A project we co-sponsored in a Dallas, Tex., general hospital assumed that if a family member has a psychiatric illness so acute as to require hospital care, his family also may be sufficiently disorganized to require considerable long-range health and welfare services. A de-

liberate effort was made to marshal the various community health and welfare services for the families of the patients who are admitted for psychiatric treatment. We hope to learn if the assumption is accurate and whether the marshaling of the services results in some demonstrable long-term rehabilitation or maintains the health of these families, or both.

We need to remind ourselves frequently that community mental health is not the exclusive property of our agency. And since many other State agencies and organizations are vitally interested in, and frequently initiate, mental health services, it seems important for us to develop and maintain good communication with them. Some of these are the crippled children's services; programs dealing with tuberculosis, chronic disease, alcoholism, venereal disease, and occupational health; State departments of education; State universities, especially extension divisions; medical and nursing schools; housing agencies; divisions of child welfare; vocational rehabilitation agencies; institutional services for the mentally ill and mentally retarded children; and mental health associations.

A State agency for community mental health might well collaborate with one or more other State agencies to strengthen services for children deprived of maternal care. State child welfare agencies usually have the responsibility for licensing children's institutions. Children in such institutions are definitely a population at risk for whom few State mental health programs are doing anything.

Another program might be to provide psychiatric consultation in crippled children's clinics. Public schools have a variety of mental health services, many of them initiated by State departments of education or by local school systems.

We have hardly scratched the surface in developing industrial mental health programs, yet there is currently a great deal of interest in mental health among occupational health people. Projects to prevent delinquency are started almost daily, and the State mental health agency should at least be informed about them. Other currently popular projects are community rehabilitation of the mentally ill, mental health services to the chronically ill, and counseling services for the aged. Activities

Inapparent Infection

Relation of Latent and Dormant Infections To Microbial Persistence

WALSH McDERMOTT, M.D.

BOTH microbes and man have an extraordinary degree of adaptive plasticity with reference to their respective environments. For centuries, man has been constantly changing his external environment and using his adaptive capacity to survive therein. In recent decades, however, man has greatly increased his capacity to alter his internal environment. And, it is man's now frequently altered internal environment to which the microbes that inhabit man must adapt if they are to survive.

When the Cornell University Medical College opened for the new term in the fall of 1958, I happened to draw the assignment of

Dr. McDermott, who is Livingston Farrand Professor of public health and preventive medicine at Cornell University Medical College, delivered the Dyer Lecture on December 16, 1958, at the National Institutes of Health, Public Health Service. A leading investigator in the field of infectious diseases, he has authored a large number of articles for scientific journals and contributed to medical classics on chemotherapy, pneumonia, and syphilis. He has also held posts of distinction on advisory and study panels of the Public Health Service.

discussing the first case at the clinical-pathological conference. The case record started off as follows:

A 43-year-old white Italian stock clerk was admitted to the New York Hospital-Cornell Medical Center for the first time June 4, 1957, complaining of swelling and tenderness of the right shoulder of 12 weeks' duration.

The patient was in good health until 3 months prior to admission when he noted the onset of swelling of the right arm from shoulder to wrist. This was shortly followed by fever and night sweats. Eight weeks prior to admission the right arm became painful. Shortly thereafter the skin over the right elbow became red and warm and the swelling increased. Despite initial improvement with corticotropin, steroids, and physical therapy, the discomfort in the right arm increased and admission was advised. A firm small right supraclavicular mass had been present for about 18 months. He had had an episode of "dry" pleurisy at age 21. One brother was known to have multiple cutaneous lipomata.

Physical examination revealed a well-developed, well-nourished white male who appeared neither acutely nor chronically ill. . . .

I shall omit the detailed presentation of the remainder of the findings in this case. I simply wish to call to your attention that the man was 43 years old, had considered himself to be per-

can be worked out. Whether the staff development program is on a State or regional basis, we must inaugurate it early or we shall find ourselves with insufficient staff or a staff that is not able to move forward into new program areas.

Yet even the best staff is on shaky ground in attempting its program planning alone. Some mechanism is essential to obtain the counsel and advice of both professional and citizen leaders in shaping broad program outlines. The staff will be kept closer to reality if there is a general advisory committee or a general committee and a technical committee.

Program Criteria

The following tentative criteria for a comprehensive, effective, and reasonable State program for community mental health are based on the foregoing assumptions, principles, and questions. As we become more experienced, the list should be critically reviewed and revised at regular intervals.

1. Are all four levels of prevention covered by some agency in the State if not by the State mental health agency?

2. Are existing services being developed with an attitude of experimentation, testing, and re-testing?

3. Are there areas of activity with both well-known and less well-recognized risk groups?

4. Is there a built-in evaluation component for all program activities?

5. Are program areas being planned and carried out in cooperation with other agencies to stimulate them to expand their own preventive activities in mental health?

6. Are at least some program areas of the State agency tangible, dramatic, and convincing?

7. Does the program encourage citizen as

well as professional participation in policy-making, at both the State and local levels?

8. Is the program's content timed both for current public concern and long-range needs of the State?

New Water Pollution Control Division

A new Division of Water Pollution Control has been established in the Bureau of State Services, Public Health Service. Gordon E. McCallum, former chief of the Water Supply and Water Pollution Branch, Division of Sanitary Engineering Services, will head the new division.

diagnostic methods it was not possible to detect the presence of corynebacteria in the tissues of the rats. Yet the evidence was quite convincing that the corynebacteria in fact were there; it was just not possible to demonstrate that they were there. Once the rats received cortisone, this infection—that could not be introduced experimentally from the outside—exploded “from the inside,” so to speak, and formed a tissue-destroying and eventually fatal disease.

The question arises as to whether it was the presence of the latent corynebacterial infection or the absence of the appropriate tissue environment that created the host resistance against our attempts at experimental infection. In any case, once the cortisone influence was established, it was the corynebacteria, and not any of the other microbial species residing in the rats, that were resurrected to the production of destructive disease. Once again we may well inquire: Why *Corynebacterium*?

In this particular case we do have a little more of a lead from studies, some by LeMaistre and others and some by György and by Zucker and their associates in the precortisone era (2, 3). These studies have shown that certain specific dietary deficiencies can provide the appropriate environment for the resurrection of *Corynebacterium* in the tissues. In short, we have a glimpse here of the sort of specificity that we sense must be present in these microbial adaptations to their environment.

Retreat into Latency

The two examples cited thus far have been concerned with one end of a phenomenon: the apparent resurrection of a microbial slumberer that is then able to surpass its fellow competitors so successfully that it finally overcomes its host. Let us turn now to what might be viewed as the other end of the phenomenon, namely, how a microbe that is surrounded by a tissue environment wholly appropriate for its flowering as disease nevertheless assumes the latent state. How does the microbe that is living openly in the host “go underground?” Or, more precisely, can either the microbe or the ideal tissue environment be artificially modified so that microbial latency is the outcome?

An approach here that immediately comes to

mind is to modify the tissue environment by infiltrating it with one or more antimicrobial drugs. For the past 15 years or so our group at Cornell has been attempting to do just this. And, I can say that we have found only one situation in which it has been possible regularly to make an infection vanish from the tissues.

In all other situations with a variety of microbial species and a large number of antimicrobial drugs, the most that it has been possible to do is to keep an infection suppressed at very low but detectable levels in the tissues. The one exception has to do with tubercle bacilli of human origin and a derivative of the nicotinamide series known as pyrazinamide.

When tubercle bacilli subsisting in the tissues of the mouse are simultaneously exposed to pyrazinamide and another antituberculous drug for an appropriate period, all of the tubercle bacilli vanish from the tissues of the animals. By “vanish” is meant that the presence of tubercle bacilli in the animal tissues can no longer be demonstrated by the most elaborate techniques of microscopy, culture, or animal inoculation. The administration of pyrazinamide alone will likewise cause the tubercle bacilli to vanish if they have just previously been exposed to isoniazid for an appropriate period. When the pyrazinamide is administered entirely alone, that is, without either prior or concomitant administration of another drug, the vanishing phenomenon does not occur, and the effects of pyrazinamide seem to be of the same type as those of other antituberculous drugs, notably isoniazid. In the last-named circumstances, the populations of tubercle bacilli in the animal tissues steadily fall during the early weeks of chemotherapy and then stabilize at a low census at which they persist throughout many months of continued chemotherapy. These two phenomena, the vanishing of “drug-influenced” tubercle bacilli when exposed to pyrazinamide and the persistence of tubercle bacilli when exposed to isoniazid or to pyrazinamide alone, may be seen in figure 2, which depicts an experiment that has been repeated many times (4).

In actuality, the vanishing of the bacilli does not represent their complete elimination from the tissues of all the animals. When a 90-day period of pyrazinamide-isoniazid administra-

fectly well until 3 months previously, and on physical examination had appeared neither acutely nor chronically ill.

Revival of Microbial Slumberers

During the next 7 months this man had many trials and tribulations including such things as widespread tuberculosis of lymph nodes and lymphosarcoma. His multiple serious ailments were all brought under excellent control by the careful and wisely chosen application of some of the wonders of modern medical science. Indeed, he attained a symptom-free state and was able to leave the hospital for a short period. Nevertheless, this gallant patient and his most dedicated physicians were finally conquered by his developing an infection with *Monilia albicans*, a common microbe that characteristically lives harmlessly in man.

Presumably, when the patient was born he was not carrying *Monilia* but neither is there any reason to believe that he "caught" the monilial infection in the weeks preceding his death. In all probability, throughout most of his adult life the microbes of *Monilia* were living quietly somewhere in his tissues. This was presumably the case whether or not by our relatively crude diagnostic methods it would have been possible to detect them there amid the welter of other microbes for which he played the host. The point that concerns us is the fact that from this welter of other micro-organisms it was this particular one, *Monilia*, that found the environmental conditions for arising and conquering. In short: Why *Monilia*?

Let us turn now from the bedside to the laboratory and regard other examples of infection. Some 7 or 8 years ago, as was correctly fashionable at the time, we were engaged in our laboratory in studying the influence of cortisone and corticotropin on infections, notably experimental infections with tubercle bacilli.

In one part of these studies, LeMaistre and Tompsett chose a model consisting of avian tubercle bacilli and the rat, in order to have an infection that was generally mild in character (1). In figure 1 may be seen the type of caseating necrotic lesion observed in the lungs of the rats infected with avian tubercle bacilli and maintained on cortisone. The avian tu-

Reproduced with the permission of the Journal of Experimental Medicine, reference 1

Figure 1. Lesions of the lung of a rat which received cortisone but was not inoculated with tubercle bacilli.

bercle bacilli could be recovered by culture of these tissues.

The initial inference was the natural one that a characteristically mild tuberculous infection had been enhanced to the point of fulminating caseonecrotic disease by the influence of the cortisone. On more careful study, however, it was revealed that the avian tubercle bacilli had nothing to do with these caseonecrotic lesions. Instead, it was found that the entire process was a disease known as pseudotuberculosis produced by quite a different microbe, *Corynebacterium pseudotuberculosis muris*.

In the absence of cortisone, the members of the rat colony uniformly showed a high degree of natural resistance to the corynebacteria when attempts were made to infect them by various routes. For this and other reasons it seemed wholly improbable that the corynebacterial infection in the animals given cortisone represented a cross-infection occurring after the start of the cortisone. Despite careful and detailed investigation, however, it was not possible to demonstrate that the rats were already harboring the corynebacteria at the time they received the cortisone.

In other words, by the use of all available

light, digestive upsets, or menstruation. As techniques for tissue culture have been developed it has become clear that the cells employed are not infrequently the site of an inapparent infection. Another case in point is the activation of an inapparent viral infection of bacteria, a bacteriophage, by appropriate change in the environment, with resultant destruction of the bacteria. Thus it is becoming increasingly recognized that inapparent infection is a broad biological phenomenon involving all sorts of microbes and every sort of host including man, lower animals, plants, and even the microbes themselves.

In the present discussion no attempt will be made to cover this field throughout its entire breadth. Dubos has a recent publication on latent infection (5), and one of his associates, Dr. Harold Simon, has virtually completed a comprehensive review of the subject which is scheduled to appear as a monograph in the latter half of 1959. Consequently, in the following discussion, attention is limited to the phenomenon of inapparent infection as it applies to bacteria and fungi because here, with antimicrobial drugs, it is possible to manipulate inapparent infections and to draw certain relatively elementary inferences concerning their nature.

The Dormant State

Thus far, the discussion of inapparent infections has centered around latent infections. It seems to me that a latent infection can be regarded as an extreme form of microbial adaptation. For, inapparent infection can exist and eventually give rise to serious disease without the microbes ever having assumed a truly latent form. In a sense, this is merely semantics, but I have found it helpful to follow the practice of subdividing infections into those which are latent and those which are dormant.

The term "latent infection" is reserved for situations in which the presence of the microbes cannot be demonstrated by any method now available and the fact that infection is present can only be demonstrated in retrospect by the emergence of overt disease (usually as a relapse).

A dormant infection is one in which the presence of the microbes can be easily demonstrated

but they are not producing disease. In a dormant infection, the micro-organisms may be living openly as the so-called commensals in the respiratory or enteric flora or less obviously in the healed lesions of previous disease as in those of the tuberculin reactor and probably also the typhoid carrier.

As we view things today, the emergence from inapparent infection to openly progressive disease occurs far more frequently with dormant infections than it does with latent infections. This could change, however, and especially what could change are our techniques for detecting the presence of latent infections.

The Antimicrobial Drug

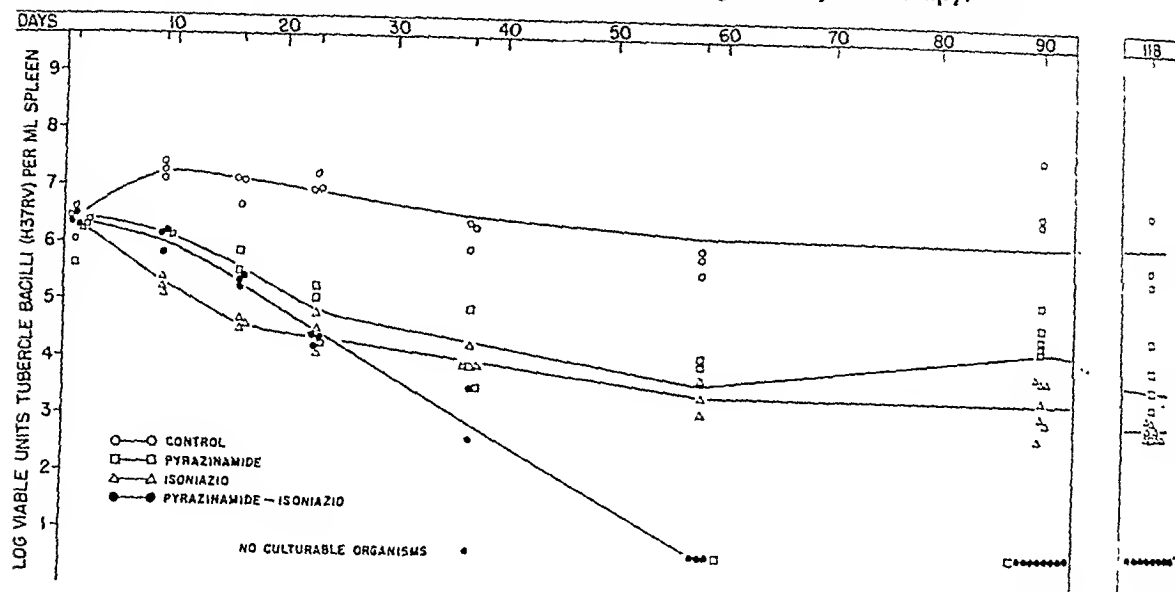

In attempting to analyze the phenomenon of microbial persistence it has seemed to me that there are five possibilities that merit consideration:

The first two are the possibilities that drug resistance of the genotypic form or inadequate drug dosage might be responsible. These can be dismissed from further consideration by virtue of the fact that experiments designed to test these possibilities have shown that they do not apply. Likewise a third possibility that microbial persistence is a result of a failure of the delivery of the drug to the parasite because of impenetrable barriers by abscess walls, fibrin membranes, or areas of necrosis can also be dismissed on the basis of appropriate experiments conducted both in our own laboratory and elsewhere.

One aspect of this barrier question does deserve special mention, however, and that is the effectiveness of intracellular residence as a sanctuary from drugs present in the intracellular fluid.

We are accustomed to hear the statement that such and such an antimicrobial drug "does not penetrate the monocyte" or some other type of cell. It is not generally realized that the type of experiment cited is not usually designed to measure whether the drug is or is not transferred across the cell boundary. Instead what is actually shown in most such experiments is that a particular microbial species, when situated within a cell, is less susceptible to a particular drug introduced into the extra-

Figure 2. Influence of pyrazinamide and isoniazid used singly and together on populations of tubercle bacilli in mouse spleens during 118 days of therapy.¹

¹ Infecting inoculum: 2.0×10^6 culturable units of tubercle bacilli.

tion was followed by a 90-day treatment-free interval, the bacilli reappeared in approximately one-third of the animals. In these animals, therefore, a truly latent infection had been induced with spontaneous resurrection after a drug-free interval of 60 to 90 days. Whether the other animals that showed no microbial revival in the 90-day period of observation also had latent infection cannot be stated, but we believe it to be the case.

There are obvious parallels between this artificially induced latent infection with tubercle bacilli and the latent monilial and corynebacterial infections of the man and the rats. In all three cases there was a stage at which there is every reason to believe that the microbes were present in the tissues, yet not the slightest trace of their presence there could be detected. In all three cases the resurrection from the latent state did not occur until the tissue environment, the external environment of the microbe, had undergone some modification. With the corynebacterial infection of the rats, the change in the nature of the environment provided by the tissue represented some consequence of cortisone.

With the fatal monilial infection of the man, the nature of the environmental change in the tissues is not clear, but the various microbial species in natural competition with *Monilia* had been suppressed and cortisone had also been given. With the infection made latent artificially, the usual environment provided for the tubercle bacilli by the tissues of the mouse was obviously perfectly suitable for the full expression of the microbes. Consequently, for microbial resurrection no tissue modification was necessary other than to free the environment of the pyrazinamide.

The two examples of "naturally" occurring inapparent infection that have been chosen were simply those most readily at hand and represent the expression of the phenomenon by a fungus and by a bacterium. A familiar example of inapparent infection with a virus is provided by the commonplace happening of the breaking out of cold sores around the lips caused by resurrection of the virus of herpes simplex. In an infected person, this event will occur predictably when the environment provided for the virus by the tissues has been modified by such factors as fever, excessive sur-

of the microbe but might have to do exclusively with activities of its early youth, for example, cell-wall synthesis. In such a case, the newborn microbe might resemble a protoplast with its capacity to carry on metabolic functions including limited cell division but without the capacity to multiply freely (6,22).

It is believed that the assumption of this state of drug indifference is induced or favored by the influence of the environment on the microbe. Included in these environmental influences are other antimicrobial drugs and intermicrobial relationships as well as the influences of the cellular and humoral defense reactions of the host and the reactions of inflammation. An environmental change of a particular sort may make the same parasite display widely different behavior to different drugs or may make different parasites display less than their maximal susceptibility to the same drug. For these reasons it is believed that it is the adaptive plasticity of the microbe that is the important factor in the influence of environment on drug effectiveness and not a chemical or physical antagonism exerted directly by the environment on the drug.

Expressed differently, pus does not neutralize drug activity, but in adapting to a necrotic environment a microbe may become less susceptible to a drug. Although instances of drug enhancement from environmental adaptation of the microbes do occur, thus far they have not been observed to lead to total eradication of a microbial population. Consequently, the net overall effect of the various environmental influences on drug effectiveness is in the direction of providing situations that favor microbial persistence.

Presumably this state, or these states, of drug indifference closely resemble, perhaps are identical to, the microbial states associated with latent or with dormant infections. Thus in concept, if not in actuality, microbial persistence may be regarded as merely the induction of the latent or the dormant microbial state by drugs.

The Parasite's Morphological Changes

Consideration of the phenomenon of microbes in the latent or in the dormant state naturally gives rise to speculation on the possible nature of such states. This is particu-

larly the case with the latent state because the question immediately arises as to the form that could be assumed by the tubercle bacilli or the corynebacteria so that they might be able to exist in the tissues without our being able to find them.

In the first place, it must be recognized that our methods for microbial detection are so relatively crude that the microbes need not change their form in order to "vanish" completely. All that would be necessary would be for the microbes to lose the ability to grow on our artificial culture media. A population of tubercle bacilli, for example, must be quite large before it is readily detectable by direct microscopy so that if it had lost its ability to adapt to artificial media, it would be undetectable.

In recent years the concept that microbes might possibly exist in more than one form has become respectable, almost fashionable. Moreover, with full realization that our inability to detect microbes during latency may simply reflect the crudity of our diagnostic methods, there remain, nevertheless, certain features of latency that suggest a major change in the form of the microbe.

The principal feature has to do with the time sequences involved in the pyrazinamide-induced latent tuberculous infection. For the uniform induction of latency, a total period of 12 weeks of chemotherapy was required. The pyrazinamide and companion drug could be administered together for the entire 12-week period or 4 weeks of treatment with isoniazid followed by 8 weeks of pyrazinamide could also suffice. But variations of these time-dose relationships, keeping the 12-week period constant, would not suffice. For example, merely reversing the order in which the two drugs were given in the sequential experiments or reducing the initial isoniazid therapy to 2 weeks instead of 4 weeks would result in a failure to induce latency. Obviously, a number of inferences are possible from these observations, but the relative precision of the time-dose requirements suggests the operation of some process that requires considerable time.

The resurrection of the tubercle bacilli from the latent state likewise required a considerable period. It must be remembered moreover, that the tissue environment in which the resurrec-

cellular environment than is the case when both the microbe and the drug are allowed to come together outside the cell.

In short what one observes is that microbes within cells are less drug susceptible than microbes outside cells; what one *infers* is that the drug was not transferred into the cell.

In reality, in the few cases in which the actual transfer of a drug has been measured, such as in Eagle's careful studies with isotopically labeled penicillin at the National Institutes of Health (7), it is found that quite substantial quantities of drug are transferred. Indeed, the quantities of penicillin transferred are more than sufficient to exert full effectiveness, so when the intracellular microbes are not fully susceptible, and sometimes they are not, some other explanation must be found.

From Eagle's studies on penicillin transfer and from some observations on penicillin-staphylococcus-leucocyte systems by Tompsett (8), it does not appear that the persistence of a minority of the intracellular staphylococci is due to a failure in drug delivery. Instead, the persistence within the phagocyte seems to be merely a replica in miniature of microbial persistence in the body as a whole.

The fourth possibility is that the environment of the inflammatory lesion exerts an antagonistic influence on the activity of the antimicrobial drug.

Although in the past I have done as much as anyone to promulgate this concept, I no longer believe it will stand up to critical scrutiny (9). It is easy to show that environmental changes result in changes in drug effectiveness. This is particularly striking in the fact that the same microbial species situated in the different organs of the same animal show widely different susceptibility to the same drug. For example, tubercle bacilli in the lung of the mouse are far more susceptible to isoniazid than tubercle bacilli in the spleen. Moreover, tubercle bacilli in the spleen are far less susceptible to streptomycin than the staphylococci in the spleen of the same animal species.

When tested in conventional circumstances *in vitro*, tubercle bacilli are quite unaffected by pyrazinamide. When the environment of the bacilli is altered, however, either by making it

more acidic or by situating the bacilli within monocytes, tubercle bacilli of human (but not bovine) origin become highly susceptible to pyrazinamide. A recent report by Williamson (10) shows that a change from an anaerobic to an aerobic environment doubles the effectiveness of dihydrostreptomycin on *Escherichia coli* over a wide range of pH. By contrast, with *Aerobacter aerogenes*, the enhanced drug activity in the aerobic environment occurs only at pH 7 or above. Since in both sets of circumstances the drug is the same, the effect of the environmental change on drug influence must be something directly related to the parasite and not a direct environmental antagonism of the drug.

Thus a number of examples exist wherein a change in environment has been accompanied by a change in drug effectiveness. In each case, however, the result could equally well have represented an influence of the environment on the parasite. Some of the examples of environmental influence, moreover, represent influences that could only have been exerted on the parasite. In view of these considerations together with the fact that a large excess of drug should usually be present in the lesion, it appears that environmental antagonisms of drug activity may well occur, but that seldom, if ever, should it attain a magnitude that would provide a satisfactory explanation for the phenomenon of microbial persistence.

The State of Drug Indifference

The fifth possibility is the one that in my opinion fits the evidence. In brief, the concept is that microbial persistence is the result of the ability of microbial populations to assume a state in which they are neither permanently incapacitated by a drug nor do they multiply freely in its presence as do the genetically drug-resistant microbes.

I have designated this state, which can be demonstrated *in vitro* and *in vivo*, as "drug indifference."

The concept of drug indifference does not imply marked suppression of all metabolic functions of a microbe but merely those related to a particular drug. The metabolic functions do not necessarily continue throughout the life

environmental change by assuming quite a different form and that this may occur within the animal body. It is of interest that the corynebacteria and mycobacteria involved in the two latent infections I have been using as illustrations are included in the list of organisms that can assume a protoplast-like form. Moreover, it is especially relevant to the present discussion to note that for some microbial species protoplast formation can be regularly induced by appropriate exposure to penicillin. The protoplasts so induced are not destroyed by penicillin, and when the penicillin is removed from the environment the protoplasts revert to the vegetative (and penicillin-susceptible) form of the microbe.

Obviously, it would be intriguing to attempt to study the pyrazinamide-tubercle bacillus relationship from the standpoint of protoplast formation especially in view of the long period necessary for microbial resurrection in the tissues.

As mentioned previously, however, we must keep constantly in mind the fact that our detection techniques for the customary forms of bacteria are so relatively crude that nonculturable but morphologically typical microbes could survive undetected in the tissues.

It might well be questioned whether there is any value in attempting to divide inapparent infections into those which are dormant and those which are latent on so artificial a basis as the ability or inability to detect the infective agent at a particular point in time. As long as this contrivance does not make us prisoners of our thinking, I believe it serves a useful purpose at this time when our knowledge is so elementary. For, the distinction keeps open the prospect that in a latent infection the microbe may be structurally and functionally in a state quite different from the microbe of overt disease or the carrier state. Along with this goes the corollary possibility that in the phenomenon of resurrection from latency to overt disease, the activation of complicated mechanisms within the parasite may be as essential as the appropriate changes in the environment provided by the host. By contrast, with a dormant infection all that may be necessary is a lapse in host defenses for the infection to become disease.

Microbial Persistence

Let us return now to consideration of experimentally induced latent and dormant infections in laboratory animals. As you will recall it was emphasized that the vanishing of the drug-influenced tubercle bacilli when they were subsequently or concurrently exposed to pyrazinamide in the tissues represented the only instance in our experience in which a microbe became truly latent as a consequence of chemotherapy. This experience includes studies with staphylococci, streptococci, *Klebsiella*, and *Brucella* as well as tubercle bacilli, and it includes all of the available antimicrobial drugs. In the case of tubercle bacilli alone, some 13 drugs with demonstrable antituberculous activity have been studied when administered singly and in various multiple drug regimens. With two compounds, a thioamide of nicotinic acid and streptovaricin, results approaching those of the pyrazinamide phenomenon were noted, but true latency could never be produced with uniformity throughout all the animals studied.

Obviously, tubercle bacilli possess the equipment to assume the latent state, but the process apparently has to be invoked in some highly specific way. Some notion of the degree of specificity that must be involved may be seen from the fact that this capacity of human tubercle bacilli to respond to pyrazinamide by assuming latency is not shared by the very closely related tubercle bacilli of bovine origin. At least one other microbe, *Treponema pallidum*, probably possesses the capacity to assume the latent state both in rabbits and man as a result of drug exposure. This point cannot be established with certainty, however, because of our lack of culture techniques whereby the tissues could be subjected to reasonably searching scrutiny to show the nondetectability of the treponemas during a latent state.

In contrast with the rarity of drug-induced latent infections, the production of dormant infections occurs regularly with all microbes studied when exposed in the tissues to an appropriate antimicrobial drug. Indeed in the experiments with latent tuberculous infections, dormant infections were produced in the groups of animals that received isoniazid or pyrazinamide as single drug therapy (fig. 2). In each case, the populations of tubercle bacilli fell

tion occurs is presumably quite favorable for the proliferation of the tubercle bacilli. Yet in the animals in which the bacilli reappear after a 90-day treatment-free interval, it has not been possible to demonstrate their presence at the 30-day or the 60-day observation point. Even when sufficient cortisone is given to evoke other microbes during the first 30 days after therapy, no resurgence of the tubercle bacilli has been demonstrated.

This appreciable delay in the reappearance of the tubercle bacilli in an apparently favorable environment and our inability as yet to hasten the process by artificial "stresses" suggest that a significant modification of the parasite was necessary before resurrection could occur. In other words, the time relations suggest that the microbial adaptation represented by the latent state of tubercle bacilli is not something that is rapidly responsive to transient fluctuations in the status of the host defenses. By contrast, resurrection of tubercle bacilli from the dormant state can occur with rapidity. The speed with which resurrection from the latent state (as contrasted with awakening from the dormant state) occurs might vary considerably among the microbial species and might likewise depend, to some extent, on the rapidity with which the appropriate environmental alterations could be accomplished.

What could be the nature of a morphological change that might accompany the physiological state of latency? Certain studies of this general subject of the existence of other forms of well-known microbes have employed antimicrobial drugs, notably penicillin, to induce the novel microbial forms. This was the case with the minute colonial forms of staphylococci, the so-called dwarf forms, and more recently with the studies of L-forms and bacterial protoplasts.

When the outer, rigid wall of a bacterial cell is removed under appropriate conditions (or its synthesis prevented), the bacterial cytoplasm and its cytoplasmic membrane may continue to exist. This surviving unit is known as the protoplast. The protoplast can carry on many, perhaps all, of the metabolic functions of the original cell except cell-wall synthesis.

It is the process of cell-wall synthesis that

appears to represent the site of action of penicillin and the protoplasts of penicillin-susceptible microbes are unaffected by penicillin. The protoplasts also appear to possess the capacity to multiply but to what extent such newborn protoplasts can survive is not yet established. These minute "peeled grapes," so-to-speak, are quite fragile and are especially susceptible to oxygen and to changes in the osmolarity of the environment.

There is some reason to believe that all protoplasts from the same microbial species are not alike. Consequently, Weibull, who is one of the outstanding investigators in this field, believes it is valuable to distinguish between true protoplasts in which no trace of the outer cell wall remains, and "protoplasts" or protoplast-like structures to which some fragment of a cell wall may remain (11). Weibull regards true protoplast formation as being something that has been clearly demonstrated for only a few microbial species and the protoplast-like phenomenon as being something more common.

In any case, the literature today contains a number of reports of observed "protoplast" formation among such micro-organisms as staphylococci, tubercle bacilli, enterococci, and many others. Moreover, a number of workers have come to regard the process of protoplast formation as being identical with what happens in the first stage of the formation of the L-form from the normal vegetative form of certain bacteria.

Despite their fragility, protoplasts can survive in vitro with appropriate manipulations of the environment. Moreover, if L-forms are protoplasts or protoplast-like structures, they would represent one form that survives in vitro where indeed the osmotic homeostasis might be expected to be more protective.

Wittler and associates in Washington have shown that the L-form of corynebacteria can be converted to the familiar vegetative form in HeLa cells by appropriate changes in the environment of the host cells (12). Wittler has also shown the same phenomenon for *Haemophilus pertussis* in mouse tissues (13).

Thus there is accumulating quite a respectable body of evidence to the effect that many microbial species are capable of responding to

crobes in a dormant infection have the capacity to assume different morphological states. In contrast with a latent infection, however, there is in a dormant infection no delay or difficulty in cultivating the microbes in their orthodox form.

Before leaving this question of possible morphological changes in the parasite in the tissues, I should like to make a brief comment on the matter of the role of the host in maintaining an infection in the dormant or the latent state. Presumably, the host plays an important role here both through the known host mechanisms of defense, by similar mechanisms as yet unrevealed, and by not providing certain types of environment such as those produced in the tissues during starvation or in the cortisone-treated animal. What I would like to point out, however, is that in quite properly focusing our attention on the host in the host-parasite reaction we have tended to regard the parasite as something that is passive and relatively constant in nature whether it is actively producing disease or living quietly in the tissues. In so doing we have tended to regard the difference between the latent and the active stages of an infection as depending almost entirely on the momentary status of the host defenses and have been neglecting the wide range of individual expression possessed by the parasite. It seems quite likely that evocation of an infection from the latent state might require some rather substantial adaptive changes by the parasite and not merely a failure of some defense mechanisms of the host. The difference between a dormant infection such as an arrested tuberculous lesion in the lung and a latent infection such as syphilis might hinge on this very point: that for resurrection to disease, the latter would require changes in the microbe itself.

Point of Drug Susceptibility

While considering the role of the host in maintaining an infection in the dormant or latent state it is also appropriate to consider to what extent antimicrobial therapy can exert an influence in this respect. The question might be phrased by inquiring whether microbes that are not actively producing disease are likely to be drug susceptible. A fair amount of information is available on this point. The

information is derived both from laboratory studies and from five clinical situations in which it has been possible to observe the effects of drug therapy administered in the early hours after the moment of infection. In all five clinical examples (syphilis, malaria, scrub typhus, tuberculosis, Q fever), the antimicrobial therapy was not eradicated, but simply held the situation frozen, so-to-speak, for as long as its administration was continued.

The observations on these various diseases suggest that there exists a stage to which the host-parasite reaction must mature before the infection is fully drug susceptible as measured by post-treatment relapse (9). In the Tigertt-Benenson studies of Q fever it was shown that this particular stage of maturity is not necessarily so old as the stage of evolution to the full clinical illness (14). When the treatment was started before this stage, however, it was clearly ineffective and served only to produce a slight prolongation of the incubation period of the clinical illness.

From these five clinical examples (6-9) and especially the two that were conducted experimentally by Smadel and Woodward and their associates (15) and by Tigertt and Benenson, it is clear that the phenomenon of drug indifference or microbial persistence can be present from the very beginning of an infection. Even at the earliest stages of an infection when the untreated microbial population is presumably at its lowest census, the introduction of antimicrobial therapy is by no means totally eradicated. In these circumstances, moreover, it is important to note that microbial persistence can occur without evoking the host-immune response characteristic of that particular infection. As a practical matter it makes no real difference whether certain microbes in an infecting population are drug indifferent at the time of implantation or whether the whole process of conversion to drug indifference occurs after infection has been accomplished and drug therapy started. In either case drug indifference can be present in the early moments of infection, and this fact is obviously of crucial importance with respect to chemoprophylaxis.

Many factors are presumably involved in the successful transmission of one or more microbes from one host to another, and the actual physi-

sharply after the start of drug therapy but then stabilized at a low census at which they remained throughout the many weeks of continued therapy.

As mentioned previously, this survival of the microbes in the tissues at a constant low census despite appropriate drug therapy can be shown for a number of microbial species and all available antimicrobial drugs. Indeed this phenomenon, which I like to designate microbial persistence, represents a biological property of very broad but perhaps not unlimited generality. In the treatment of infections in humans, the existence of the phenomenon of microbial persistence need not necessarily lead to therapeutic failure but most failures that occur stem from it. Moreover, in addition to providing the basis for post-treatment relapse, microbial persistence is obviously responsible for the post-treatment carrier state. In short, it is this phenomenon which is responsible for our inability to eradicate an infection uniformly from a group of patients or from a community by the use of drugs.

Our group at Cornell has been specially preoccupied with this phenomenon of microbial persistence ever since early 1946. An extensive review of these studies has been published recently (6). Accordingly, I shall attempt to present the subject only in sufficient outline to provide a proper basis for a subsequent consideration of latent and dormant infections. In so doing it will be necessary to employ bold assertions at certain points without bringing forward the experimental evidence that has seemed to me to be convincing. This evidence is offered in the published presentation.

In this brief consideration of microbial persistence, we start from the demonstration both in patients and in laboratory animals that microbes that are drug susceptible in the orthodox sense are nevertheless able to survive in the tissues despite the prolonged administration of the appropriate antimicrobial therapy. The horizontal trend lines of the census of microbes during therapy seen in figure 2 are merely one graphic representation of this point. Indeed, about the only situations in which antimicrobial therapy can be totally eradicated in humans are with the relatively fragile *Neisseria* and possibly also with dysentery bacilli.

The close resemblance of the microbial states of drug indifference to those of the naturally occurring latent and dormant infections may be seen in the phenomenon of drug-resistant "persisters." It is quite clear that the general phenomenon of microbial persistence is not a result of the presence or emergence of genotypically drug-resistant microbes. Indeed with the experimental model employed in figure 2, when a microbial population is resistant to a particular drug the census in the tissues does not fall on administration of the drug. Moreover, when the population is drug susceptible at the beginning but is transformed in the course of therapy to one that is drug resistant, the drug-induced downward trend of the census is reversed and the microbes proliferate freely in spite of the continued administration of the drug. But sometimes this microbial resurgence does not occur. Instead the population that has been markedly reduced by drug therapy (and is now predominantly drug resistant) simply remains at the low census throughout long periods of continued drug therapy. In short, the drug-resistant microbes behave like drug-susceptible persisters.

Unfortunately, it has not been possible to conduct the obvious experiments on the fate of these drug-resistant persisters in the period after the antimicrobial therapy has been discontinued. It is possible, however, that the situation here may resemble the paradoxical situation discussed below in connection with chemoprophylaxis in which a microbial population that is drug indifferent is nevertheless under the continued influence of the drug. What can be said at this point about the resistant persisters, however, is that microbial populations (including the drug-resistant cells) obviously can become dormant or latent within an animal body by processes not necessarily dependent on antimicrobial therapy.

The possible morphological changes in the microbe to go along with the altered metabolic states have been considered in terms of latent rather than dormant infections. The latent state appears to represent a more extreme form of microbial adaptation than the dormant state, and hence it is to the latent state that attention is understandably directed. Obviously, it cannot be stated at this time whether the mi-

crobes in a dormant infection have the capacity to assume different morphological states. In contrast with a latent infection, however, there is in a dormant infection no delay or difficulty in cultivating the microbes in their orthodox form.

Before leaving this question of possible morphological changes in the parasite in the tissues, I should like to make a brief comment on the matter of the role of the host in maintaining an infection in the dormant or the latent state. Presumably, the host plays an important role here both through the known host mechanisms of defense, by similar mechanisms as yet unrevealed, and by not providing certain types of environment such as those produced in the tissues during starvation or in the cortisone-treated animal. What I would like to point out, however, is that in quite properly focusing our attention on the host in the host-parasite reaction we have tended to regard the parasite as something that is passive and relatively constant in nature whether it is actively producing disease or living quietly in the tissues. In so doing we have tended to regard the difference between the latent and the active stages of an infection as depending almost entirely on the momentary status of the host defenses and have been neglecting the wide range of individual expression possessed by the parasite. It seems quite likely that evocation of an infection from the latent state might require some rather substantial adaptive changes by the parasite and not merely a failure of some defense mechanisms of the host. The difference between a dormant infection such as an arrested tuberculous lesion in the lung and a latent infection such as syphilis might hinge on this very point: that for resurrection to disease, the latter would require changes in the microbe itself.

Point of Drug Susceptibility

While considering the role of the host in maintaining an infection in the dormant or latent state it is also appropriate to consider to what extent antimicrobial therapy can exert an influence in this respect. The question might be phrased by inquiring whether microbes that are not actively producing disease are likely to be drug susceptible. A fair amount of information is available on this point. The

information is derived both from laboratory studies and from five clinical situations in which it has been possible to observe the effects of drug therapy administered in the early hours after the moment of infection. In all five clinical examples (syphilis, malaria, scrub typhus, tuberculosis, Q fever), the antimicrobial therapy was not eradicated, but simply held the situation frozen, so-to-speak, for as long as its administration was continued.

The observations on these various diseases suggest that there exists a stage to which the host-parasite reaction must mature before the infection is fully drug susceptible as measured by post-treatment relapse (9). In the Tigertt-Benenson studies of Q fever it was shown that this particular stage of maturity is not necessarily so old as the stage of evolution to the full clinical illness (14). When the treatment was started before this stage, however, it was clearly ineffective and served only to produce a slight prolongation of the incubation period of the clinical illness.

From these five clinical examples (6-9) and especially the two that were conducted experimentally by Smadel and Woodward and their associates (15) and by Tigertt and Benenson, it is clear that the phenomenon of drug indifference or microbial persistence can be present from the very beginning of an infection. Even at the earliest stages of an infection when the untreated microbial population is presumably at its lowest census, the introduction of antimicrobial therapy is by no means totally eradicated. In these circumstances, moreover, it is important to note that microbial persistence can occur without evoking the host-immune response characteristic of that particular infection. As a practical matter it makes no real difference whether certain microbes in an infecting population are drug indifferent at the time of implantation or whether the whole process of conversion to drug indifference occurs after infection has been accomplished and drug therapy started. In either case drug indifference can be present in the early moments of infection, and this fact is obviously of crucial importance with respect to chemoprophylaxis.

Many factors are presumably involved in the successful transmission of one or more microbes from one host to another, and the actual physi-

cal transfer of an infecting population to a new host is not necessarily followed by their successful maintenance there. The presence of a prophylactically administered drug in the fluids of the new host might well make the difference between the success or the failure of the implanted microbes to survive. What must be recognized, however, is that even if an antimicrobial drug is present in the tissue fluids at the time of the initial microbial seeding there is no reason to doubt that some of the microbes may survive as persisters. Consequently, the possibility seems highly likely that chemoprophylaxis—to the extent that it is employed to try to prevent actual infection—will only be uniformly successful with the very few highly fragile microbes, such as gonococci, meningococci, or dysentery bacilli, that appear to have little capacity to survive as persisters.

Although the premature drug therapy was ultimately unsuccessful in the five examples cited, it was clear that the infections were suppressed as long as the antimicrobial therapy was continued. This implies that the microbial populations were both drug indifferent and drug influenced at the same time. Presumably, what happens in this apparently paradoxical situation is that a significant proportion of the microbial population is in fact drug indifferent and remains so. But as the tissue environment contains antimicrobial drug, whenever individual microbes revert from drug indifference to a state of drug susceptibility or new cells are born into this state they are promptly inhibited by the drug. As a result the population as a whole is kept constantly suppressed, a condition I like to describe as being in a state of physiological imprisonment.

In the clinical instances cited, the physiologically imprisoned microbes were able to resurge to the point of producing clinical illness once the antimicrobial drug was removed from the tissue environment. It is conceivable that if the physiological imprisonment were maintained for a sufficiently long period, the microbial populations might die off completely in some cases and in others assume a latent or dormant state that would continue even in the absence of drug. Presumably something akin to the last-named possibility occurs in the puzzling case of drug-resistant persisters.

It would hardly be proper, in a discussion of inapparent infection, to fail to note the possibility that latent or dormant infections, either natural or drug associated, are capable of damaging the tissues by their continued presence there. This is the sort of speculative exercise that can rapidly get out of hand. Nevertheless, it seems appropriate to mention a few diseases, associated with microbial infection, in which demonstration of the indicted microbe in the tissues in its recognizable form has either never been accomplished or has been accomplished only rarely. The two principal diseases in this category are syphilis and rheumatic fever. Sarcoidosis might possibly represent a third example, but the indirect association of these lesions with tubercle bacilli is considerably less definite than the indirect association of rheumatic carditis with streptococci or tabes dorsalis with *T. pallidum*.

The fact that tabes dorsalis is caused by *T. pallidum* is generally accepted, yet the presence of the spirochete in the lesions has never been convincingly demonstrated. To some extent this situation is not comparable with that of other infections because no method exists whereby *T. pallidum* can be cultured. Nevertheless, *T. pallidum* can be demonstrated by microscopy of stained tissue in certain other lesions of syphilis, notably parenchymal disease of the brain and in the lungs and liver of syphilitic newborn. In the pre-penicillin era, the lesions of tabes dorsalis were generally considered to represent the sterile end result of a previous involvement with *T. pallidum*. It came as a considerable surprise, therefore, to note clinical improvement in the so-called "lightning pains" of tabes dorsalis when afflicted patients were treated with penicillin. To be sure, evaluation of improvement in "lightning pains" is notoriously difficult, but long-experienced clinicians were convinced that penicillin influenced them. Thus an antimicrobial drug appears to exert its influence in lesions that hitherto were not considered to contain microbes. As noted above, however, the possibility remains that the lesions of tabes dorsalis represent an active syphilitic process, and it is merely our inability to cultivate *T. pallidum* that makes the situation seem at all unusual.

The lesions of rheumatic carditis are not gen-

erally believed to represent a direct tissue reaction to the presence of streptococci but some type of unusual host reaction to previous streptococcal infection elsewhere in the body. Moreover, on microscopic examination of the lesions of an acute rheumatic carditis, streptococci are not to be seen. Nevertheless, reports recur of the successful cultivation of streptococci from the acute lesions of acute rheumatic carditis in patients who have died during the acute stage of the disease (16-19). These reports have been made by knowledgeable people who have presented their findings with great diffidence. In today's climate of opinion, however, the general tendency with respect to the observations has simply been to look the other way. In experiments in rabbits, however, Denny and Thomas have shown that group A streptococci could persist in the tissues for many weeks and could then be evoked to the stage of bacteremia by the administration of cortisone (20). Whether, prior to evocation, they were dealing with a dormant or truly latent infection cannot be stated because the experiments were not designed for the specific study at this point.

Thus, with all due respect to the many more widespread beliefs concerning the relationships of *T. pallidum* to tabes dorsalis and streptococci to rheumatic fever, the possibility that these microbes in dormant or latent form are actually present in the respective lesions cannot be excluded.

Our Contemporary Challenge

What is the magnitude of the problem we face today with respect to this resurrection of infectious from the inapparent state to the state of progressive disease? It is quite clear that the problem is a formidable one and by its very nature is bound to become even more so in the future. Indeed, it is not always appreciated that in the economically developed countries today it is these endogenous infections that constitute virtually the entire load of illness caused by all forms of microbial disease except those caused by viruses. In short, on an individual basis today, but on one that is bound to steadily widen, man is beginning to succumb to his own microbes.

All that is necessary to see this is to enter an adult ward of a general hospital any morning and inquire what problems are present that day with respect to infection. This is an experience that I happen to have every 6 weeks as part of our teaching program, and it is most illuminating. Certain points immediately become evident. First, a surprisingly important portion of the disease load on a general hospital ward on any one day is still caused by microbial infection. Second, no one microbial species or genus is particularly involved but rather the disease load is caused by a relatively wide assortment of microbes. Third, despite the heterogenicity, these disease-producing microbes have one outstanding characteristic in common: they all form what is customarily regarded as the normal microbial flora of man.

Thus the microbes causing the greater portion of our morbidity in hospitalized patients today are the familiar microbial species that through the years we have grown accustomed to regard without fear. On any one day the disease assortment will include infections produced by *E. coli*, *A. aerogenes*, *Proteus*, *Pseudomonas*, nonhemolytic streptococci, and *M. pneumoniae*. Two other microbes, staphylococci and tubercle bacilli, likewise deserve inclusion on the ground that although they are capable of producing disease they commonly inhabit our bodies without doing so. Approximately one-half of any group of adults are carriers of potentially pathogenic staphylococci. With tubercle bacilli the situation depends on one's age. It is estimated that 40 percent of the population of the United States over the age of 30 are harboring living tubercle bacilli so that in effect both tubercle bacilli and staphylococci can be considered to be part of man's normal microbial flora.

All of these microbes have the capacity to survive for long periods in man without causing either benefit or harm insofar as can be detected by today's methods. But when man's internal environment is suitably altered, as is so often the case today, all of these microbes have the capacity to arise and produce serious illness.

The ways whereby man's internal environment is subject to alteration today are familiar to us all and represent the unsought portion of the consequences of our great therapeutic

advances. In ever-enlarging measure these advances are making it possible for us to permit the survival of the socially desirable but biologically unfit. This sociobiological force is not limited in its impact to infancy and childhood but is operative to a considerable extent at all ages of life. As a consequence there are many more of us who consider ourselves to be in "good health" but who have some defect with respect to our ability to make our own adaptation to the microbes around us. The defect may be in our structure or in our experience.

Even those of us who were structurally sound to begin with and who have not been overly protected against life's microbial experiences may rapidly lose our veteran status if we have to give up certain of our tissues to the surgeons or of necessity must be saturated with certain hormones. When man's internal environment was modified by politically induced states of extreme deprivation, such as in a Nazi concentration camp, the disease produced was largely microbial and was caused by the more prominent of the microbes that inhabit man (21). When crudely comparable states of deprivation are produced today by long-continued corticosteroid administration, the results are the same. And, if we accompany the tissue deprivation by a drug-induced suppression of the more prominent microbes, we get disease by the less prominent microbes such as *Monilia*.

We have been relatively slow in recognizing the importance of this problem of endogenous infection today. One part of it we seem to have almost suddenly discovered, namely, the hospital infections due to staphylococci. But we are slow in recognizing that important as staphylococci are—and I have no desire to minimize their importance—they represent, nevertheless, only a part of what is a considerably larger contemporary problem. Indeed, in terms of serious or fatal microbial disease in our adult hospital services, the intestinal bacilli and the fungi are usually even greater offenders than staphylococci. We are also too prompt to attribute successful microbial survival in this drug-ridden world to the phenomenon of genotypic drug resistance. It is not so much that drug-resistant staphylococci or the drug-resist-

ant members of other microbial genera are not important today as it is that they represent only one of the many ways whereby microbes can successfully adapt to the changes around them. The serious illness and death due to microbial disease today are not chiefly a result of once-susceptible microbes that have now become drug resistant. Instead, to an increasing extent, these diseases are being caused by microbes that never were susceptible to our drugs but hitherto have managed to persist in an inconspicuous fashion in our tissues.

As we have seen, not only does man lack the power to create life but his ability to destroy it, at least at the microbial level, is sharply limited. To the extent that this means that microbial adaptability will continue to blunt our attempts at therapy and prophylaxis, the situation might be regarded as being somewhat gloomy. But to the extent that what holds for the microbes holds for us as well, any restriction on man's ability to exterminate life has its good side too.

Antibiotic Use for Preserving Fish

The use of an antibiotic to aid in keeping fresh-caught fish in sound condition was authorized for the first time by the Food and Drug Administration in an order, effective April 21, 1959, which sets a safe limit on the amount that may remain on such food without harm to the consumer.

The order allows commercial fishermen to use the antibiotic, chlortetracycline, on fresh-caught whole, headed, and gutted fish, shucked scallops, and unpeeled shrimp. Its use is not permitted on processed seafood products, including fish cuts, steaks, and filets, peeled shrimp, and shucked oysters. Chlortetracycline has been used on poultry since 1955 and extensive data on its safety are available.

The maximum amount that may remain on the seafood has been fixed at 5 parts per million. This quantity will not always be removed in cooking, but the agency has determined that it may be consumed without harm even by persons sensitive to antibiotics. Treated seafood products must be labeled to show that they contain the antibiotic and that it has a preservative effect.

Computers and Bicycles

Malaria surveillance field teams in Thailand expect to protect 5 million people each month in house-to-house visits. For this full-scale program, a report form for rapid analysis by electronic computers has been developed.

Village surveillance records are summarized for each canton, an administrative grouping of about 10 villages. The canton surveillance summary reports, about 1,000 a month, require analysis for location, population, control operations, workload, fever cases, treatment, and malaria by age groups.

A report from the northern region explained that the first cycle of the program will probably take 4 months to complete, because time is needed to improve the procedure and many employees are new to the work. Also the shortage of bicycles has meant that men must travel on foot over trails between scattered villages that cannot be reached by jeep. However, Thai officers and men treat the program as a personal challenge and are working enthusiastically to see it through.

—J. MILES BUTLER, Ph.D., *malaria eradication adviser, Chiangmai, U.S. Operations Mission, Thailand.*

The Pitha Turned Red

By the time we reached Tarabou, a village near Dacca, East Pakistan, to investigate a report of sudden fatal illnesses, 6 children had died and 8 other people had been ill. A 20-year-old woman had the same symptoms as the younger victims, cyanosis, restlessness, abdominal pain, and signs of circulatory collapse. We learned that the children, whose ages ranged from 1 to 6 years, had died within half an hour after they became ill. The others had recovered in 3 to 5 hours and had no apparent residual effects. A chemical poison seemed to be the most likely cause of the illnesses.

The detailed food histories showed that rice and

water were the only items consumed by people who were affected. The rice had been boiled and nothing had been added to it. We checked the water which came from the river and found that the alum used to clarify it. Then we discovered that the last family we interviewed had drawn water from a nearby pond and did not use alum.

Meanwhile a sanitarian, questioning the findings independently, found that some of those who had been ill had eaten a rice cake called pitha. We then questioned all the families again; everyone who had been ill had eaten pitha.

Analysis of the rice cake showed the salt ingredient contained sodium nitrite. We learned that the woman who made the cake had asked a driver to get salt for her. He had a package of salt in the bus and handed it to her. She remembered as she prepared pitha that day, that the rice turned red.

Rural Occupational Medicine

Occupational medicine and rural hygiene are combined in the research work carried on by the State Institute of Rural Occupational Medicine and Rural Hygiene in Lublin, Poland. Prof. Dr. Józef Parnas is director of the institute and Prof. Dr. F. Wysocka is its scientific secretary.

The institute's origins are connected to Prof. Dr. Witold Chodźko, Poland's first minister of health and a member of the sanitary organizations of the League of Nations, who helped to set up the nation's first health stations in 1905.

Since the institute was established in 1951, it has conducted laboratory and field research on the effects of chemicals on agricultural workers, the working conditions of drivers of farm machinery, rural housing, and the personal hygiene and prevalence of parasites in the rural population. It has dealt with outbreaks of tularemia, Q fever, leptospirosis, toxoplasmosis, and brucellosis; and has trained rural surgeons and workers for sanitary and epidemiological stations.

The newer phenolic and vinyl base paints present less of a health hazard from lead intoxication than oil base paint, according to this study which investigates the effect of a number of variables on lead solubility.

Laboratory Study of the Solubility of Red Lead Paint in Water

D. A. FRASER, M.S., and L. T. FAIRHALL, Ph.D.

CONCERN increases over the amount of lead taken into the body as it becomes more and more apparent from analyses of food, air, and water that each of these contributes a quantity of lead each day. The maximal non-cumulative daily body burden of lead has been determined to be approximately 0.5 mg. Lead intake from sources other than water approaches this permissible maximum. If it is found that any one of the three sources contributes an undue share of lead, efforts should be made to identify that source and suggest a remedy.

In view of the extensive industrial use of red lead and red lead paints and the hygienic significance of lead compounds, it is remarkable that so very little is known about the solubility of these materials in water. According to Friend (1), red lead is "practically insoluble in water." The only value we have found in

the literature is one theoretically derived by Glasstone (2) from electrode potential measurements. Glasstone measured the electrode potential of the half element $\text{Pt} \left[\begin{smallmatrix} \text{Pb}_3\text{O}_4 \\ \text{PbO} \end{smallmatrix} \right]$ against the standard mercury-mercurous oxide electrode using identical solutions of carbonate-free-N-sodium hydroxide throughout. The value obtained of -0.610 is very slightly higher than the theoretical potential of -0.617 volt. Assuming the ionization of red lead to be $\text{Pb}_3\text{O}_4 \rightleftharpoons 2 \text{Pb}^{++} + \text{PbO}_4^{--}$ the solubility of red lead in N-NaOH is 1.1×10^{-17} gram-mol per liter at 17°C .

Our study was undertaken to determine experimentally the solubility of red lead and the extent of dissolution of lead by water in contact with surfaces coated with red lead paint. Three types of red lead paint were tested: linseed oil base, phenolic base, and vinyl base. Specifications of these paints are given on p. 502. It should be noted that the oil base paint used did not contain the added litharge found in present-day specifications. Several lots of oil base paint, some ground commercially and some in the laboratory, were studied. In a supplementary experiment the three types of red lead paint were exposed to the solvating action of natural and treated waters from eight localities in the United States.

Since the data were obtained in the laboratory

Mr. Fraser, a chemist, is with the Occupational Health Branch, Division of Special Health Services, Public Health Service, at Field Headquarters in Cincinnati, Ohio. Dr. Fairhall, formerly with the branch, is deceased. Dr. Herbert E. Stokinger, chief toxicologist of the branch, and the staff of the Division of Sanitary Engineering Services provided many helpful suggestions in the critical review of the manuscript. (Manuscript received for publication February 9, 1959.)

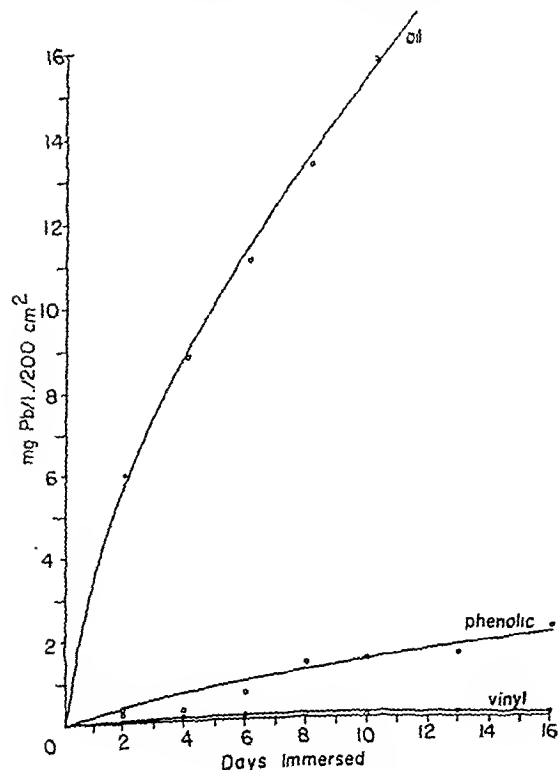

and selected variables affecting the solubility of lead were studied separately, the study does not apply to all variables, acting in combination, that may be encountered in the field. For a valid toxicological appraisal of the amounts of lead in water, samples taken from tanks actually in use with various types of water would have to be analyzed.

Red Lead Powder

The chemical procedures for determining the amount of lead taken up by water in contact with red lead may be interfered with by (a) the particle size of the red lead, (b) the colloidal tendency and penetration through filtering media, and (c) adsorption of lead by the filtering medium.

Measurements of the particle size of the samples of red lead powder showed an average of 0.8 micron (μ), with a range from 1.3μ to the lower limit of visibility of the optical micro-

Specifications and Formulas for Paints Tested

Oil Base

From Federal Standard Stock Catalog, Section IV, Part 5. Federal Specification for Paint; Red Lead Base, Ready Mixed, TT-P-86a (May 4, 1949), type I.

Component	Percent by weight
Red lead (Fed. Spec. TT-R-191, type I, grade C)-----	77.53
Aluminum stearate (Navy Spec. 52 A 12)-----	.23
Raw linseed oil (Fed. Spec. TT-O-369)-----	10.90
Pale heat-bodied linseed oil (Navy Spec. 52020)-----	3.78
Mineral spirits (Fed. Spec. TT-T-291, grade 1)-----	6.45
Liquid drier (Fed. Spec. TT-I-651, type I)-----	1.11
	100.00

Phenolic Base

From Federal Standard Stock Catalog, Section IV, Part 5: Federal Specification for Paint: Red Lead Base, Ready Mixed, TT-P-86a (May 4, 1949), type IV.

Component	Percent by weight
Red lead (TT-R-191, type I, grade C)-----	55.90
Magnesium silicate (TT-M-90)-----	4.36
Diatomaceous silica (52-MC-522, type I)---	5.25
Aluminum stearate (52 A 12)-----	.26
Phenolic varnish-----	25.35
Aromatic petroleum spirits (TT-N-97, type II)-----	7.60
Diptene (TT-D-376)-----	.94
Lead naphthenate (24 percent Pb)-----	.08
Cobalt naphthenate (6 percent Co)-----	.02
Manganese naphthenate (6 percent Mn)-----	.02
Antiskinning agent (National Aniline ASA)---	.13
	100.00

Vinyl Base

No Federal specification available. Red lead vinyl resin paint, supplied by National Lead Co., Brooklyn, N.Y.

Component	Percent by weight
Red lead (TT-R-191, type I, grade C)-----	23.70
Aluminum stearate-----	.10
Vinyl resin—VAGH-----	16.35
Tricresyl phosphate-----	1.64
Toluene-----	25.31
Methyl isobutyl ketone-----	25.31
Carbitol (low gravity)-----	7.59
	100.00

scope, about 0.5μ . A suspension showed active Brownian movement, and the colloidal aggregates precluded filtration through even the best grade filter paper. A certain amount of colloidal lead invariably penetrated the filter, as shown by the Tyndall effect, with resultant erroneously high values.

The adsorption of lead on the filter paper causes erroneously low values. O'Shea (3), who first demonstrated the adsorption of lead by filter paper, showed that filtration of dilute lead acetate solution resulted in a loss of approximately 0.2 mg. of lead in 50 cc. of solution. Preliminary experiments in this study showed that filter paper adsorbed lead from neutral solution to such an extent that three filtrations of an optically clear solution of 1 mg. of lead salt per liter of water removed 99 percent of the lead.

Ordinary filtration procedure was therefore excluded, and pressure filtration through cellophane with the Zsigmondy type of apparatus was resorted to. When wettable cellophane, designated as 600-PUT-O, was used as the filtering medium under a pressure of 150 kg./cm.²

Figure 2. Effect of drying time on dissolution of lead from oil base red lead paint.

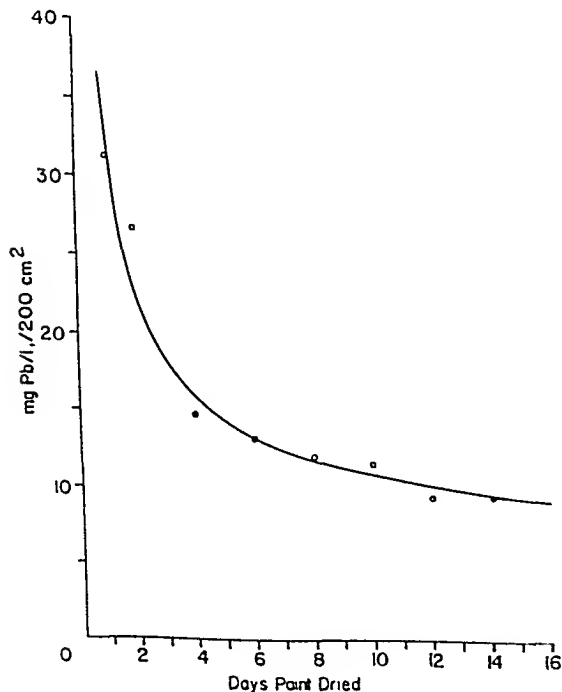

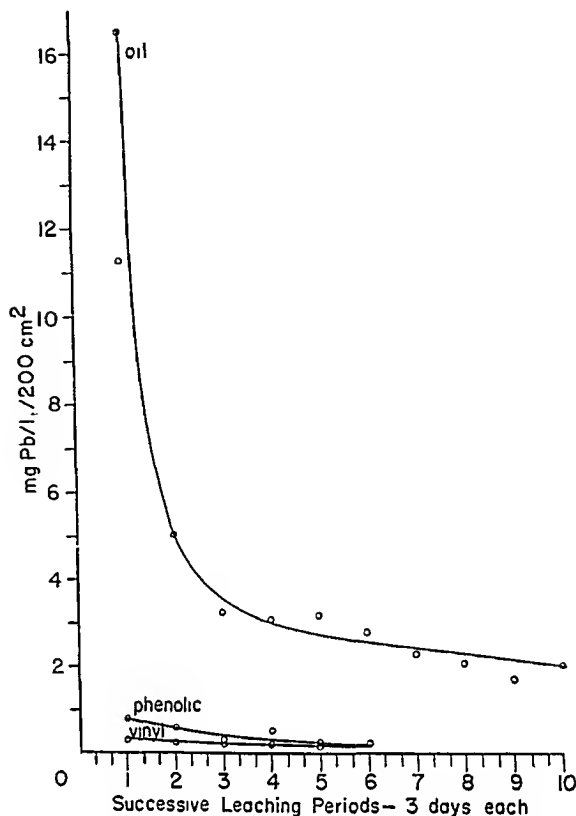

Figure 3. Effect of successive leaching of red lead paint film with water.

NOTE: Drying time for oil base paint: 10 days.

of nitrogen gas, no detectable lead loss occurred and the filtrates were optically clear.

Suspensions of red lead in distilled water were shaken in Pyrex bottles until equilibrium was reached. The lead content of the pressure-filtered solutions was determined by the chromate method of Fairhall and Keenan (4). This analytical method was chosen because, being a titration method, it is applicable over a wide range of concentrations without dilution of the sample or other extrapolation of results.

Because of probable contamination of red lead with the more soluble lead monoxide, reagent-quality red lead was purified by Glass-tone's method by repeated treatment with sodium hydroxide (1), and then washed with dilute acetic acid. The successive portions were analyzed for lead until constant values were obtained.

Purified reagent grade red lead powder gave an average value in distilled water at room tem-

perature of 5.53×10^{-4} gram of lead per liter (0.553 ppm) or 8.9×10^{-7} gram-mol of Pb_3O_4 per liter. Suspensions of red lead in distilled water gave only a slightly greater amount of lead in true solution after standing for 1 year.

Red Lead Paint

The investigation of red lead paint was concerned solely with the lead in solution. Particulate lead oxide or particles of lead paint film resulting from blisters or pinholes and mechanically swept into suspension, while hygienically important, were completely removed, and the results in all cases refer only to lead in true solution.

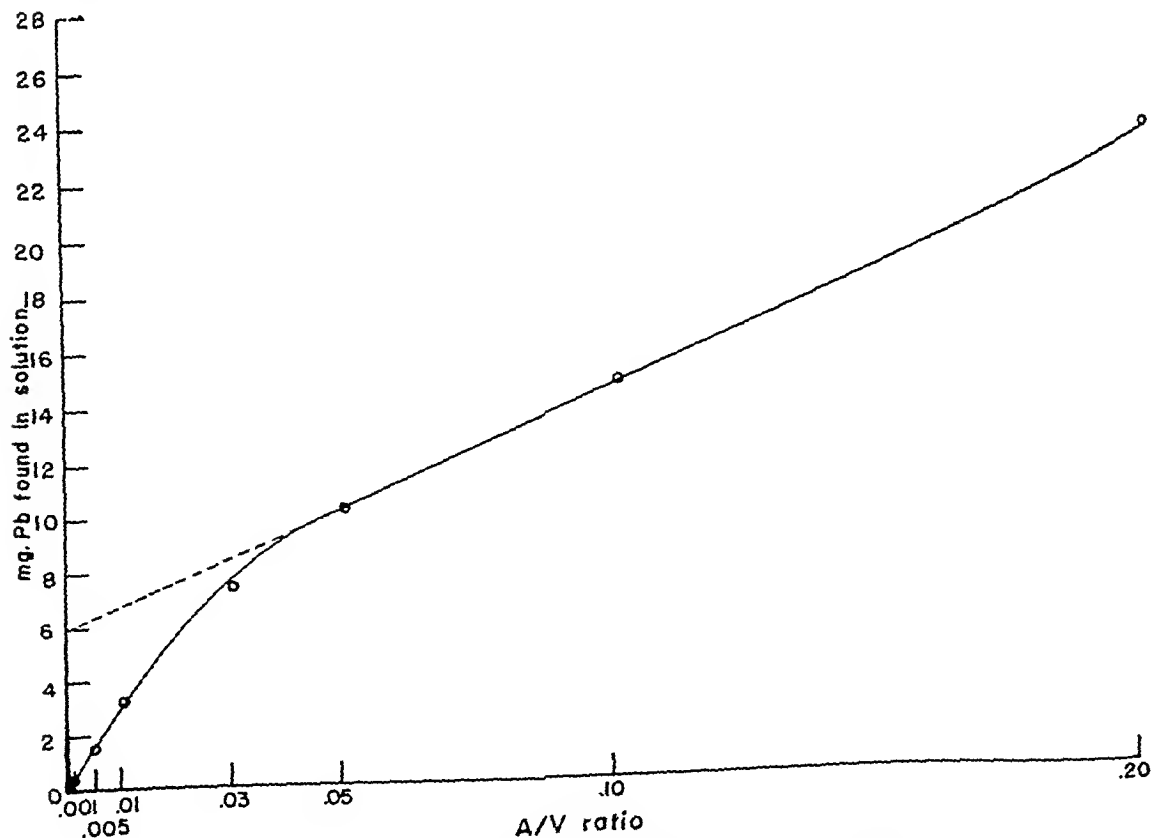

Although the effect of water alone was of primary interest, the effects on lead solubility of sodium hydroxide, sodium hexametaphosphate, free chlorine, and differences in alkalinity and acidity were also studied.

For most of the tests the paint was applied

to glass surfaces. Glass was used so that the results would reflect the solution tendency of the paint film itself rather than the effect of possible interaction of the paint film and metal surfaces. Several dozen glass plates were cut to measure 3 inches by 6 inches from stock 0.3 cm. thick. Areas of 100 cm.² were measured and marked off on each plate. The plates were washed, cleaned with nitric acid and distilled water, dried, and painted to the desired area, and the paint film was allowed to dry for appropriate periods. In studying the oil base paint, various drying times were tested. The drying time of the phenolic and vinyl base paints was less important, since drying consists principally in evaporation of the solvents (5).

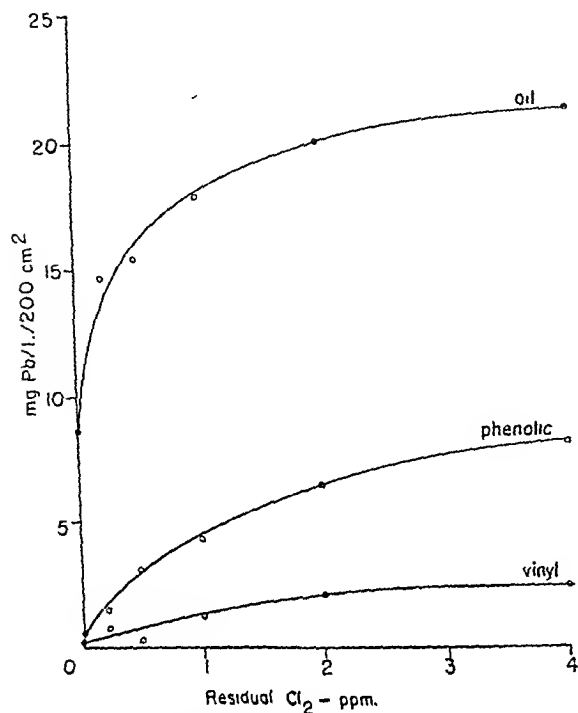

Water solubility tests were also made for lead from the three paints on black iron and on galvanized iron plates. The red lead paint was applied directly to the iron plates or over an undercoating of zinc-chromate primer.

Figure 4. The amount of lead in solution plotted against the area/volume ratio (cm.²/cm.³).

NOTE: Data for oil base paint, with drying time of 7 days and immersion time of 3 days.

Figure 5. Effect of chlorination of water on dissolution of lead from red lead paint.

NOTE: Drying time for oil base paint: 94 days. Immersion time: 3 days.

When the primer was used, the red lead paint was followed by a coat of aluminum paint.

The painted plates, both glass and metal, were placed in tall form 1-liter beakers, and 500 ml. of either distilled water or the desired salt solution was added. The beakers were sealed with sheet Parafilm and allowed to stand at room temperature for the desired time. The plates were then removed, rinsed with distilled water, and the water was analyzed for lead by the chromate method (4).

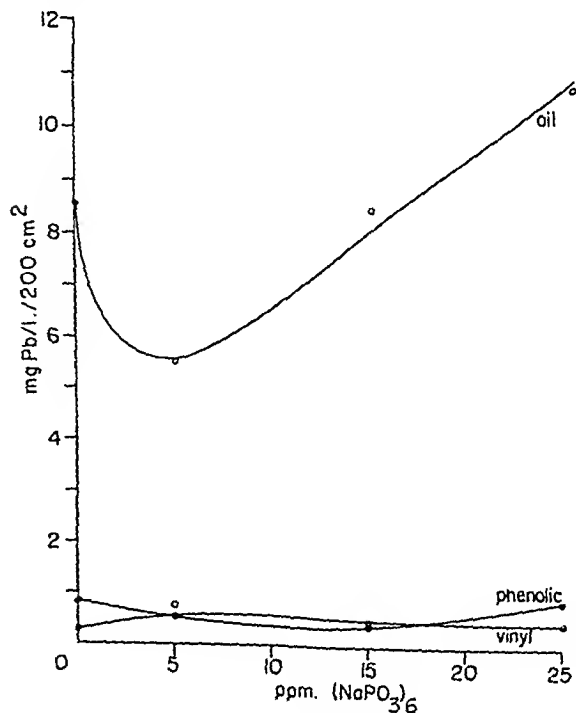

Finally, an experiment was performed in which successively smaller areas were painted with the oil base paint and dried for 7 days. These glass plates were immersed in successively greater volumes of water. After immersion for 30 days the water was drained off and tested for dissolved lead by the more sensitive dithizone method (6). This procedure permitted an investigation of the range of area/volume ratios from the experimentally determined ratios to those that might be encountered in the field.

In the supplementary investigation the three types of red lead paint were exposed to natural water. To determine the effect of variations in natural water on the solution of lead, samples of the treated city water supplies from eight localities in the United States were obtained. Areas measuring 100 cm.² on glass plates were painted with the red lead paint, and the plates were immersed in 500 ml. of each of the water samples for 30 days after the paint had dried for 7 days. The water was then analyzed for lead content by the chromate method (4).

The results of all experiments are expressed in milligrams of lead dissolved per liter of water for exposure surface of paint film of 200 cm.² In all experiments except the area/volume ratio study, the area/volume ratio was 100 cm.²/500 ml., or 1 cm.² of surface per 5 ml. of solution.

Immersion time. The results of the immersion-time experiment show clearly that the oil base paint yields increasing amounts of lead with continued exposure (fig. 1). After 10

Figure 6. Effect of sodium hexametaphosphate on dissolution of lead from red lead paint.

NOTE: Drying time for oil base paint: 97 days. Immersion time: 3 days.

perature of 5.53×10^{-4} gram of lead per liter (0.553 ppm) or 8.9×10^{-7} gram-mol of Pb_2O_4 per liter. Suspensions of red lead in distilled water gave only a slightly greater amount of lead in true solution after standing for 1 year.

Red Lead Paint

The investigation of red lead paint was concerned solely with the lead in solution. Particulate lead oxide or particles of lead paint film resulting from blisters or pinholes and mechanically swept into suspension, while hygienically important, were completely removed, and the results in all cases refer only to lead in true solution.

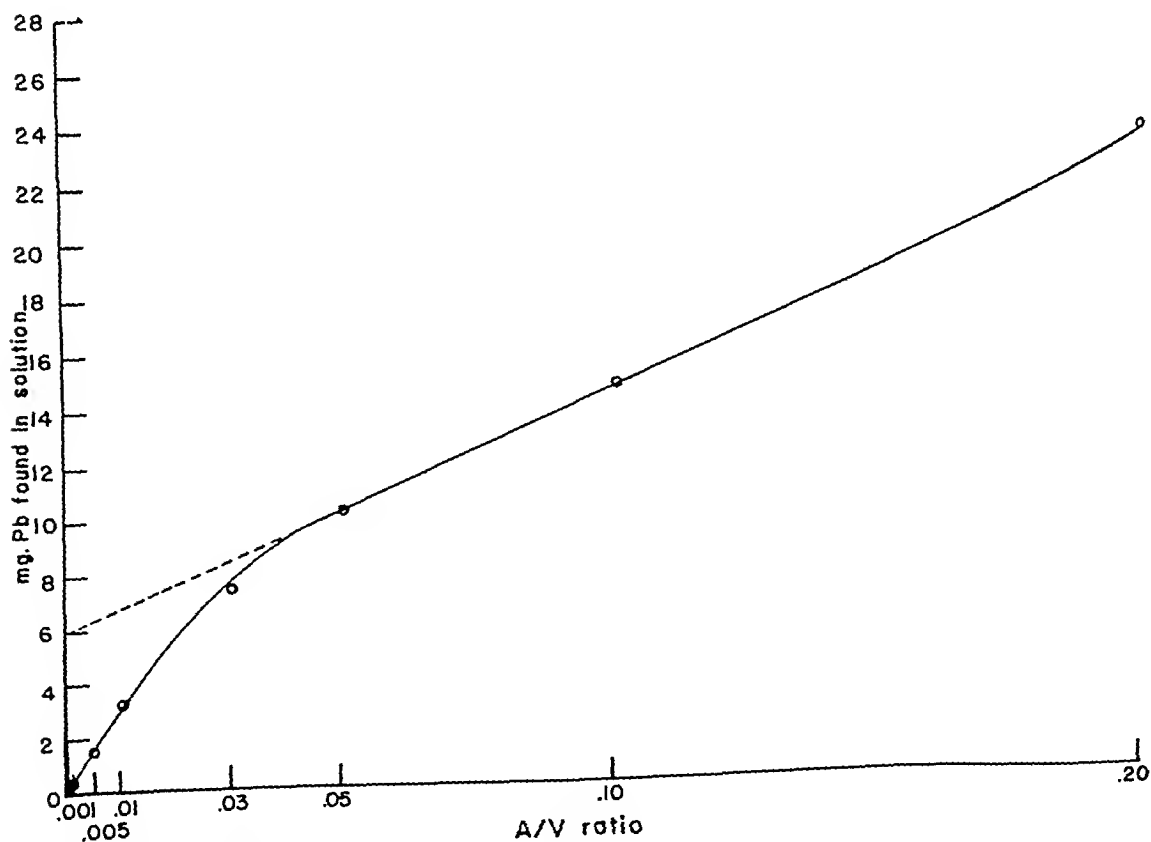

Although the effect of water alone was of primary interest, the effects on lead solubility of sodium hydroxide, sodium hexametaphosphate, free chlorine, and differences in alkalinity and acidity were also studied.

For most of the tests the paint was applied

to glass surfaces. Glass was used so that the results would reflect the solution tendency of the paint film itself rather than the effect of possible interaction of the paint film and metal surfaces. Several dozen glass plates were cut to measure 3 inches by 6 inches from stock 0.3 cm. thick. Areas of 100 cm.² were measured and marked off on each plate. The plates were washed, cleaned with nitric acid and distilled water, dried, and painted to the desired area, and the paint film was allowed to dry for appropriate periods. In studying the oil base paint, various drying times were tested. The drying time of the phenolic and vinyl base paints was less important, since drying consists principally in evaporation of the solvents (5).

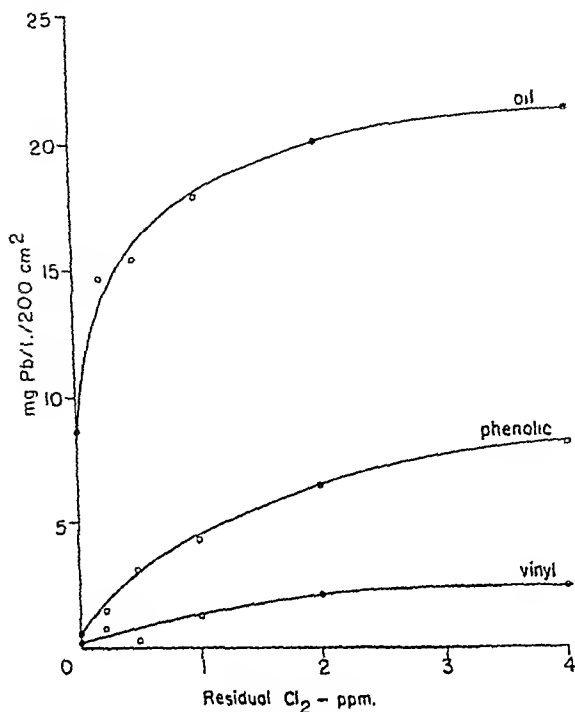

Water solubility tests were also made for lead from the three paints on black iron and on galvanized iron plates. The red lead paint was applied directly to the iron plates or over an undercoating of zinc-chromate primer.

Figure 4. The amount of lead in solution plotted against the area/volume ratio (cm.²/cm.³).

Figure 5. Effect of chlorination of water on dissolution of lead from red lead paint.

NOTE: Drying time for oil base paint: 94 days. Immersion time: 3 days.

When the primer was used, the red lead paint was followed by a coat of aluminum paint.

The painted plates, both glass and metal, were placed in tall form 1-liter beakers, and 500 ml. of either distilled water or the desired salt solution was added. The beakers were sealed with sheet Parafilm and allowed to stand at room temperature for the desired time. The plates were then removed, rinsed with distilled water, and the water was analyzed for lead by the chromate method (4).

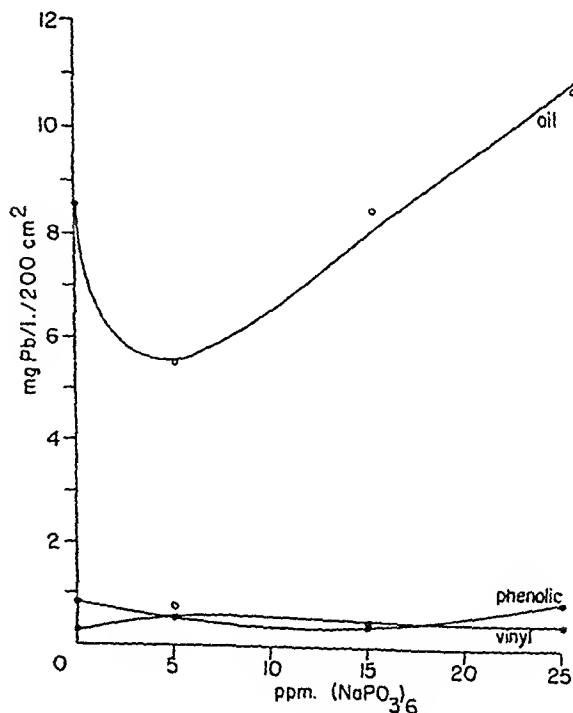

Finally, an experiment was performed in which successively smaller areas were painted with the oil base paint and dried for 7 days. These glass plates were immersed in successively greater volumes of water. After immersion for 30 days the water was drained off and tested for dissolved lead by the more sensitive dithizone method (6). This procedure permitted an investigation of the range of area/volume ratios from the experimentally determined ratios to those that might be encountered in the field.

In the supplementary investigation the three types of red lead paint were exposed to natural water. To determine the effect of variations in natural water on the solution of lead, samples of the treated city water supplies from eight localities in the United States were obtained. Areas measuring 100 cm.² on glass plates were painted with the red lead paint, and the plates were immersed in 500 ml. of each of the water samples for 30 days after the paint had dried for 7 days. The water was then analyzed for lead content by the chromate method (4).

The results of all experiments are expressed in milligrams of lead dissolved per liter of water for exposure surface of paint film of 200 cm.² In all experiments except the area/volume ratio study, the area/volume ratio was 100 cm.²/500 ml., or 1 cm.² of surface per 5 ml. of solution.

Immersion time. The results of the immersion-time experiment show clearly that the oil base paint yields increasing amounts of lead with continued exposure (fig. 1). After 10

Figure 6. Effect of sodium hexametaphosphate on dissolution of lead from red lead paint.

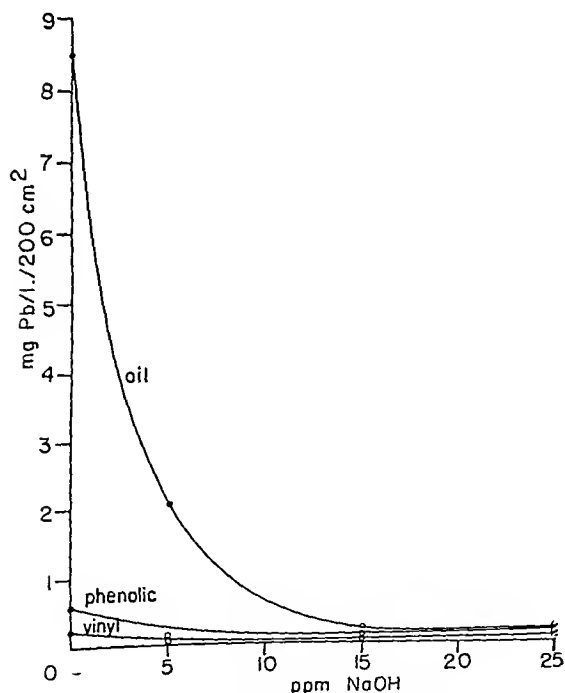

NOTE: Drying time for oil base paint: 97 days. Immersion time: 3 days.

days' immersion, the lead content of the test water was 15.8 mg. per liter. Furthermore, the oil base paint yields more lead in water than either of the other two paints. The highest value for the phenolic base paint was 2.32 mg. The highest for the vinyl base paint, which yielded the least amount of lead of any of the paints, was 0.13 mg.

Drying time. For the oil base paint, increasing the drying time from 1 day to 2 weeks appreciably decreased the release of lead, from 31.24 mg. to 9.30 mg. after 3 days' immersion time (fig. 2). Drying beyond the 2-week period caused a further slight reduction. However, an average value of 7.44 mg. per liter of water was obtained after 80 days of drying. Since the drying of the phenolic and vinyl paints consists largely in evaporation of solvent rather than the complicated chemical reactions which occur in the drying of linseed oil base lead paint, no particular change in the amount of lead in solution would be anticipated, and none was observed.

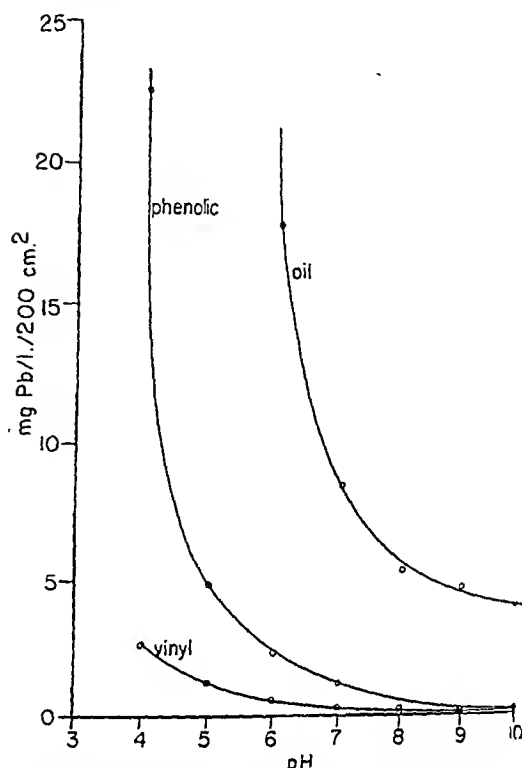

Repeated immersion. Repeated immersions,

Figure 7. Effect of sodium hydroxide on dissolution of lead from red lead paint.

NOTE: Drying time for oil base paint: 97 days. Immersion time: 3 days.

Figure 8. Effect of variation in hydrogen ion concentration on dissolution of lead from red lead paint.

NOTE: Drying time for oil base paint: 14 days. Immersion time: 3 days.

each lasting 3 days, resulted, for the oil base paint, in a decided decrease from the first high value of 16.50 mg. of lead per liter of water until a nearly constant value of 2 mg. was obtained after the 10th immersion (fig. 3). A slight decrease was also noted for the phenolic and vinyl paints, but the initial solubility was much less. The decrease was from 0.81 to 0.21 mg. of lead per liter with the former and from 0.28 to 0.19 mg. with the latter.

Area/volume ratio. As the area/volume ratio (cm^2/cm^3) decreases from 0.2 to 0.05, a straight line relationship holds (fig. 4). A further decrease results in values which lie considerably below those predicted by an extension of the straight portion of the curve.

Residual chlorine. Because public water supplies generally are chlorinated, the effect of residual chlorine on red lead was studied. With all three types of paint, lead solvency was increased by the presence of 0.0–0.2 ppm of

residual chlorine, the normal range of chlorination. With higher residual chlorine concentrations there was a further increase to a constant maximum. With the oil base paint the amount of lead dissolved in 3 days increased from a value of 8.54 mg. per liter per 200 cm.² in chlorine-free water to 14.54 mg. at a chlorine value of 0.2 ppm. Phenolic base paint under the same conditions increased from 0.59 to 1.62 mg., while vinyl base paint increased from 0.24 to 0.85 mg. (fig. 5).

Sodium hexametaphosphate. Addition to the water of low concentrations of sodium hexametaphosphate, another chemical often used in treating public water supplies, caused depression in the solubility of lead during an immersion period of 3 days (fig. 6). This effect has been noted previously by Ruchhoft and Kachmar (7) with reference to other lead salts. The solvent action of sodium hexametaphosphate was apparent only at relatively high concentrations (25 ppm). At the concentrations investigated this salt had little or no solvent effect on vinyl base red lead paint.

Sodium hydroxide. With increasing amounts of sodium hydroxide (up to 25 ppm) the amount of lead carried into solution decreased, for all three types of paint (fig. 7). With the oil base paint there was a decrease from 8.54 mg. after 3 days' immersion in distilled water to 0.23 mg. following immersion for the same period in water containing 25 ppm of NaOH.

Hydrogen-ion concentration. Variation in

pH from 4.0 to 10.0 indicated that water on the acid side of neutral has a greater solvent effect on paint film than does water on the alkaline side (fig. 8). Sodium acetate buffer with either acetic acid or sodium hydroxide was used to cover this entire range. The solution was made as weak as possible, consistent with obtaining buffering capacity, in order to limit the effect of the acetate ion and to record only the effect of the hydrogen-ion concentration. Immersion time was 3 days, and the oil base paint film was dried for 14 days prior to testing.

With all three paints, pronounced solubility of the red lead occurs at a pH of 4. The solubility value for oil base paint increased from 8.44 to 117.2 mg. per liter per 200 cm.² at this pH; for phenolic base paint it rose from 1.21 to 22.4 mg.; and for vinyl base paint, from 0.31 to 2.71 mg.

Nature of surface. Whereas most of the foregoing work was based on paint films on glass, further studies were made, as noted above, of red lead painted plates of black iron, galvanized iron, and iron plates with a priming coat of zinc chromate conditioner. When the iron plates were completely covered with red lead paint, the results were similar to those obtained with glass plates. The values were somewhat lower when the red lead paint blistered, formed pinholes, or became detached in any way so that the more basic metal was in contact with the solution. It was assumed that such decrease was due to the replacement of Pb ions by the metal higher in the E.M.F. series. Unpainted

¹ Not reported.

iron plates placed in the same beaker with glass plates coated with oil base red lead paint caused a reduction in values for the glass plates of 3.4 mg. in a test period of 7 days.

Further experiments with unpainted iron plates in a very dilute solution of lead acetate caused a drop in concentration from 9.56 mg. to 1.31 mg. of lead per 500 cc. Plates painted with vinyl base paint followed by an overcoating of aluminum paint yielded as much as 0.114 mg. of lead per liter.

Water samples. For the tests of the effect of water from city supplies, samples were obtained from localities differing widely with regard to such factors as fluorides, hardness, total solids, and pH value. The normal water data given in table 1 are average results supplied by the water departments of the various cities and are not necessarily the exact mineral content of the samples used. All water samples were tested for lead by the dithizone method before use, and no lead was found.

In the experiment with oil base paint, the amount of lead found in solution after immersion for 30 days varied from 28.9 mg. per liter for water from Amarillo, Tex., to 3.62 mg. per liter for water from Seattle, Wash. The effect of the various types of water tested on the phenolic and vinyl base paints was equally variable (table 2).

Discussion

Whereas red lead purified by Glasstone's method gives somewhat lower values than those obtained with the commercial product, the value obtained by direct measurement is greater than the theoretical figure arrived at by electrode potential measurement. An explanation of the low results which Glasstone calculated from such measurements may exist in the fact that these measurements were made in N-NaOH (40,000 ppm). Our results show that sodium hydroxide decreases the solubility of red lead within the range investigated (fig. 7). It is possible that this may hold also for higher concentrations of sodium hydroxide.

Particularly interesting in our study are the results regarding the effect of pH and certain substances on the rate of dissolution of lead. Pertinent data are summarized in table 2.

Table 2. Dissolution of lead from red lead paint on glass plates immersed for 30 days in water from eight localities

Locality	Milligrams of lead per liter of water per 200 cm. ²		
	Oil base paint	Phenolic base paint	Vinyl base paint
Amarillo, Tex.-----	28.9	0.31	0.17

Seattle, Wash.-----	3.62	.60	.58

They show clearly the increased rate of solution of lead during the test period in the presence of residual chlorine or at low pH.

It had been anticipated that the protective oxidized oil film, coating the particles of red lead and resulting from the drying of oil base paint, would tend to reduce the solvent action of water. Of outstanding interest, therefore, is the finding in this study of a greater amount of lead in solution following contact with red lead oil base paint in comparison with the amount resulting from red lead powder suspended in water. Thus, the theory that a protective film retards the solution of red lead is not tenable in this case.

Table 3. Solubility of red lead paint according to type of water

(NaPO ₃) ₆ (5 ppm)-----	5.5	.6	.8

NOTE: Drying times for oil base paint corrected for case of comparison. Immersion time: 3 days.

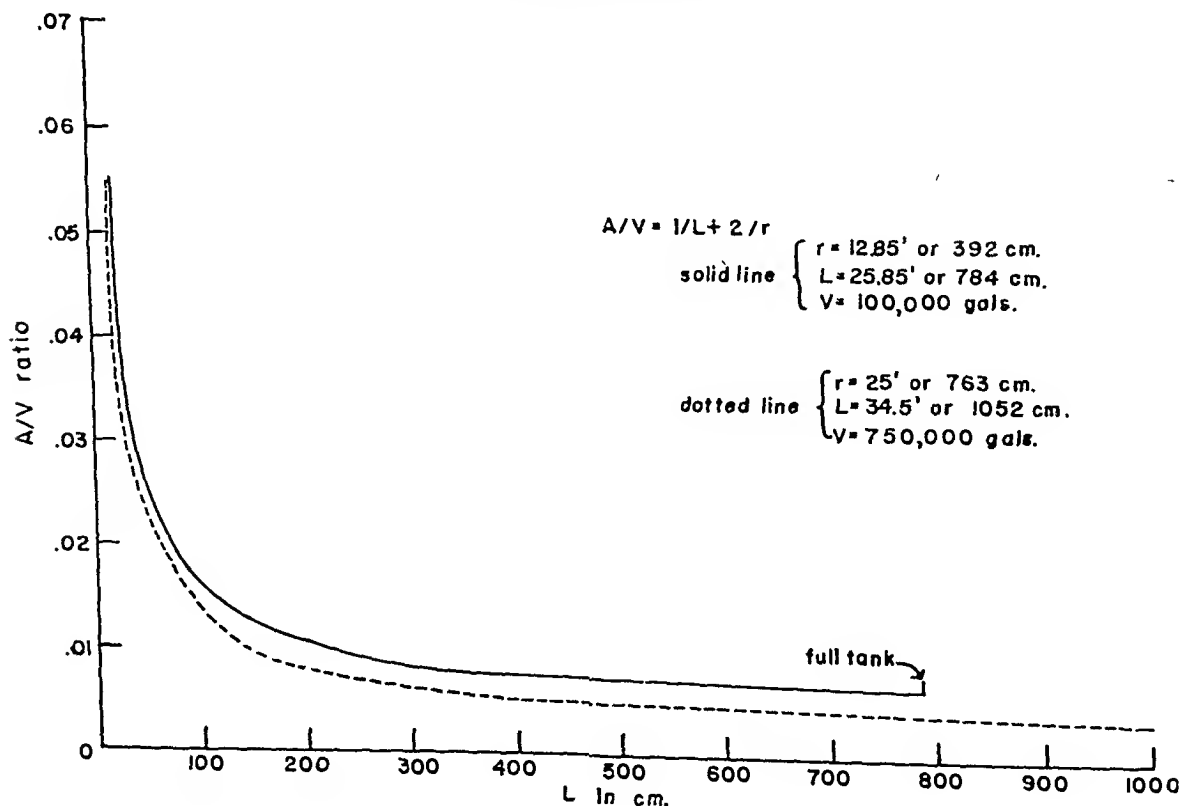

An explanation for this result is found in the effect of linseed oil on red lead itself. Red lead in contact with linseed oil results in the formation of either a small amount of lead soap, presumably lead linoleate, or a glyceride of lead (8-10). A preparation of the lead salt of the fatty acids of linseed oil exhibited solution properties similar to and values higher than the oil base film itself.

Although no figures for lead linoleate are given in the literature, values (calculated) for lead palmitate, lead myristate, lead stearate, and lead laurate (11) vary from 21.2 mg. of lead per liter of water to 46 mg. The value for the solubility of lead linoleate prepared from linseed oil used in the paint experiments in our investigation was 41.1 mg. of lead per liter of water. It is understandable, therefore, that appreciable amounts of the lead salt would leach out of this type of paint film in contact with water.

The effect of repeated leaching should provide a clue as to whether or not this was merely a surface effect yielding a relatively high initial concentration of lead, which tended to wash off and lessen in amount. The results obtained with the three types of paint exhibit such an effect. However, for the oil base paint the uptake of lead after 30 days of successive immersion approaches a nearly constant value of 2 mg. per liter per 200 cm.² of painted surface.

When the values shown in figure 3 are summed and compared with those of figure 1, it is found that, if the area of painted surface is kept constant while the volume of water is increased, the dissolution of lead from the paint surface is constant and independent of the volume. Therefore, the concentration of lead found in solution varies directly as the ratio of the area of paint to the volume of water. That this straight line relationship does not hold throughout the entire lower range of the area/

Figure 9. Area/volume ratios (cm.²/cm.³) attained in two cylindrical tanks of different dimensions as water level is increased.

NOTE: L=water height; r=tank radius.

volume ratio is shown by figure 4. The decrease in the amount of lead found at lower area/volume ratios may be due to the high initial solubility exhibited by the painted surfaces.

Figure 9 shows how the area/volume ratio changes with the water level in two cylindrical tanks the height of which is equal to the diameter. Comparison with figure 4 indicates that the values of lead concentration to be expected in normally operating public water supply tanks would be less than those determined experimentally with an area/volume ratio of 0.2.

Summary

The solubility of red lead powder and of lead from three types of red lead paint has been studied in a series of laboratory experiments. The effects of a number of variables were investigated separately.

The solubility of purified red lead in distilled water was found by analysis to be 8.9×10^{-7} gram-mol of Pb_3O_4 per liter (0.553 ppm) at room temperature.

The uptake of lead by water standing in contact with oil base red lead paint varies with the length of time of contact. In an immersion period of 6 days, 11.2 mg. of lead per liter per 200 cm.² of surface dissolved from oil base paint, 0.70 mg. from phenolic base paint, and 0.11 mg. from vinyl base paint.

The amount of lead dissolved by water in contact with oil base red lead paint varies inversely with the time of drying of the paint film.

Repeated immersion tests indicated that the leaching is partly a surface effect, and the dissolution of lead tends to approach a constant value.

Sodium hexametaphosphate causes a reduced rate of lead solvency in distilled water within the range of concentration of that used in treating public water supplies. At relatively high concentrations (greater than 15 ppm) there is an increased solubility of lead.

Sodium hydroxide up to 25 ppm depresses the rate of solution of lead with all three types of paint.

An increased hydrogen-ion concentration up to pH 4 causes a pronounced increase in the rate at which lead is dissolved from the oil base as well as the phenolic and vinyl base paints.

The nature of the material painted did not affect the lead solubility provided that no free metal was in contact with the water.

Results obtained with water samples from eight localities, differing widely in chemical characteristics, indicated that such characteristics have a profound effect on the rate of solution of red lead from paint film.

Of the three paints tested, the oil base paint was at least 10 times more soluble under the conditions of the test than either the phenolic or vinyl base paints.

f luoridation

- 1** Statement by Arthur S. Flemming,
Secretary of Health, Education, and Welfare
- 2** Report on Fluoridation in the United States
- 3** Statements on Proposed Alternatives
to Fluoridation of Water Supplies

1 Statement by Secretary Flemming

Surgeon General Leroy E. Burney has called my attention to a very significant setback in the progress of the fluoridation program during the last 2 years.

Although controlled fluoridation has been proved over and over again to be an inexpensive and completely safe means of preventing

65 percent of dental decay, only one out of every four people in this country today has this protection.

Moreover—and this is the most disturbing fact of all—the proportion of the population not benefiting from this remarkable health measure is actually increasing.

Why every community with a public water supply has not availed itself of the proved dental health benefits of controlled fluoridation is difficult for me to understand in the light of the following facts:

1. Intensive research over a quarter of a century shows conclusively that water containing a proper amount of fluoride reduces dental decay by about 65 percent.

2. Equally conclusive research has demonstrated that controlled fluoridation is completely safe, causing no bodily harm of any kind.

3. The American Dental Association, the American Medical Association, and virtually all other scientific and professional organizations having competence in the field have recommended the fluoridation of public water supplies.

4. This protection costs only a few cents per person per year. If started in childhood, the protection is effective over a lifetime.

5. Controlled fluoridation does not mean adding a foreign substance to water; all water contains some fluoride. Fluoridation of water as a public health measure simply means controlling the amount of fluoride in a public water supply.

6. Even water containing as much as eight times the amount of fluoride recommended for prevention of tooth decay does not injure a person's health. Too much fluoride in water does cause discoloration of tooth enamel but has never been known to injure health.

7. Public opinion polls reveal that the majority of people who are informed about fluoridation are favorably disposed to the idea.

I have inquired into why, in the light of all these factors, the extension of fluoridation has been lagging in the last 2 years.

I have come to the conclusion that it amounts basically to this: the opponents of fluoridation are a militant minority; the proponents of fluoridation, as is so frequently the case with proponents of new health measures, are an unmilitant majority.

In my review of the situation with Surgeon General Leroy E. Burney and his associates in

the Public Health Service, it seems to me that what is needed is a militant majority for fluoridation.

I am convinced that fluoridation would be proceeding rapidly if the question were decided on its merits by informed people.

Some informed people will, of course, continue to oppose fluoridation as a matter of principle. I respect their views even though I cannot, on the basis of the scientific evidence, concur in their conclusions.

But such persons are not, by and large, the ones who succeed in blocking local fluoridation projects.

For example, some of the most vocal opponents of fluoridation are persons who have been charged by the Food and Drug Administration with making false health claims for nostrums and devices and thereby influencing their customers against seeking needed medical service.

Dr. George F. Lull, then secretary and general manager of the American Medical Association, in an editorial in *Today's Health*, June 1955, used these words to describe the opposition to fluoridation:

"In addition to the sincere opposition which merits respect, there is the usual hue and cry from those who take every opportunity to discredit medical science and legitimate public health progress. We will find in the antifluoridation camp the antivaccinationists, the antivivisectionists, the cults and quacks of all descriptions, in short, everyone who has a grudge against legitimate scientific progress. They bring all manner of irresponsible charges, including the allegation that fluoridation is promoted for commercial profits by those who manufacture the chemicals and machinery and that irresponsible scientists and public officials have been 'bought.' The ridiculousness of such a charge evaporates into thin air when one merely looks at the official and professional bodies that have endorsed fluoridation."

As Dr. Lull implies, the kind of opposition to fluoridation which we are now experiencing is by no means new in the public health field. Indeed, this opposition is very similar to that which arose in the early days of such invaluable health measures as chlorination of public water

supplies, pasteurization of milk, and vaccination. Owing in large part to such opposition, it has taken 50 years, for example, to get widespread acceptance of chlorination. I hope that urban communities which have not yet fluoridated their water supply will not be denied this health benefit for a comparable period.

It is nothing short of tragic to deny millions of children the benefits, now and in their later years, of healthy teeth, particularly when, in addition to the scientific evidence that points to the efficacy of fluoridation, public opinion polls indicate that a majority of citizens desire to take advantage of this established health measure.

Yet this is clearly what is happening in a

number of communities large and small. For example, a poll by Elmo Roper and associates in 1957 showed that 57 percent of the people in cities of 1 million and over said fluoridation was a good idea, while only 20 percent said it was not. In communities of 100,000 to 1 million the response was 50 percent for and 19 percent opposed, while in communities of 2,500 to 100,000 it was 54 percent for and 24 percent against.

As long ago as 1953, when fluoridation was still relatively new and before the opposition became fully organized, a poll by Dr. George Gallup showed that people who knew about fluoridation favored its adoption as a community health measure by a margin of nearly four to one.

2

Report on Fluoridation in the United States

Dental decay is recognized as man's most widespread chronic disease. Few persons escape. No social stratum or age group is immune. A decayed tooth never heals by itself, by prescription, or by advice. About 97 million people in the United States have decayed teeth requiring treatment; more than 21 million others are edentulous; the average high school graduate has had 10 teeth attacked; and family dental bills total \$1.7 billion annually although only 40 percent get treatment. If everyone who needed dental care wanted it, there would not be enough dentists to provide it. The current progressive accumulation of dental disease is a heavy national burden—painful, costly, and disfiguring. This serious health problem remains largely neglected because of the undramatic nature of the disease, cost of treatment, the widespread tendency not to regard dental decay as a hazard, and insufficient professional manpower to provide care. This combination of factors points to the need for a preventive measure that is effective, safe, in-

expensive, convenient, widely acceptable, and automatic. The fluoridation of community water supplies meets these requirements.

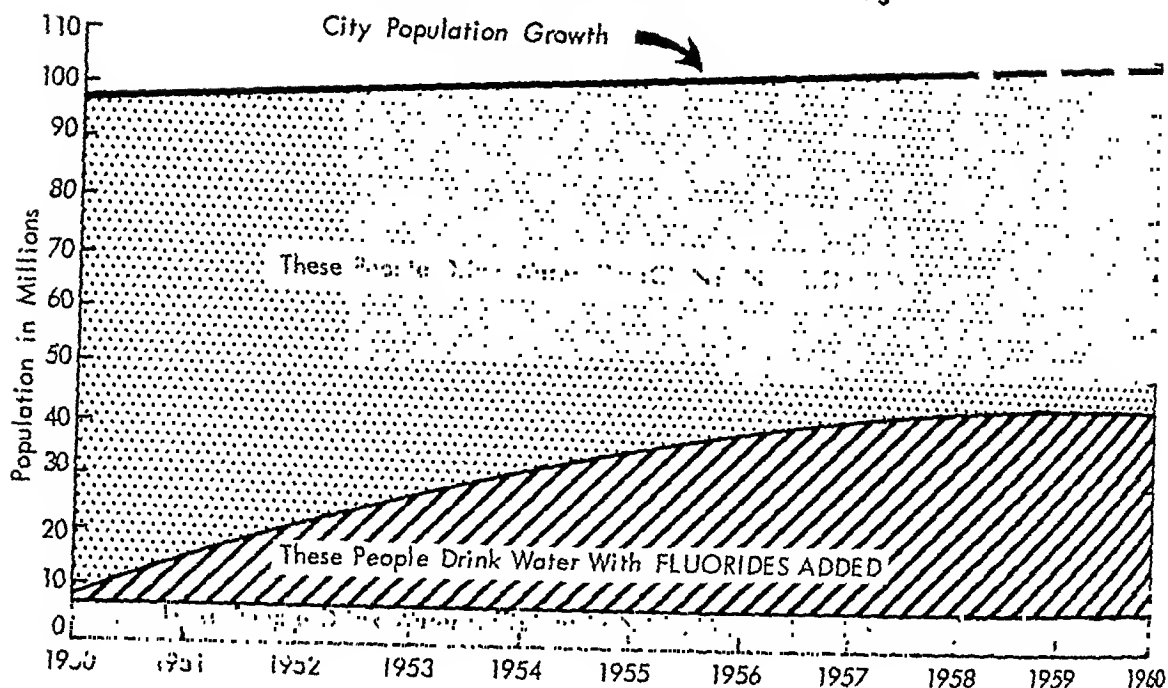

Fluoridation is the adjustment of fluoride-deficient communal water supplies to the optimal level by adding small, but precise amounts of fluoride-containing compound to yield in solution one part of fluoride in every million parts of water. In effect, it supplements the daily ingestion of fluoride to a level which effectively and safely prevents up to 65 percent of the dental decay among children, and provides protection and benefits that continue into adult life. In principle, water fluoridation is similar to standardized water-treatment procedures designed to promote the health of consumers.

Research

The early history of the fluorine and dental decay relationship goes back to the last quarter of the 19th century, when clinicians noted that less tooth decay accompanied mottled enamel. In 1916, Dr. Frederick McKay reported mottled enamel to be a waterborne disease, which in 1931 was discovered to be caused by excessive fluorides. A hypothesis evolved that trace amounts

*Prepared by the Division of Dental Public Health,
Bureau of State Services, Public Health Service.*

Urban Growth and the Fluoridation Lag

of fluoride in water might inhibit dental caries. A series of epidemiological studies was carried out by the Public Health Service led by Dr. Trendley Dean and his associates. They found a strikingly low prevalence of dental decay associated with 1 ppm fluoride in the drinking water. These studies in natural fluoride areas were confirmed by animal experimentation in laboratories and by independent scientists in other countries.

In light of the evidence that no undesirable effects accompanied the dental benefits derived from water supplies naturally containing 1 ppm fluoride, three controlled fluoridation programs were begun independently in 1945 to determine whether these benefits could be duplicated by controlled fluoridation. The results of these and other studies were remarkably uniform and demonstrated that the use of drinking water containing 1 ppm fluoride: (a) produces identical dental and general effects whether the fluoride occurs naturally or is added by mechanical means; (b) effectively, safely, and economically prevents up to 65 percent of tooth decay; and (c) does not produce observable mottling of the teeth.

Although alternative techniques and vehicles have continued to be tested, none of them to

date can substitute for fluoridation as a public health measure. (See statement on proposed alternatives, p. 517.) In the absence of water fluoridation or, where water fluoridation cannot be practiced, direct application of topical fluorides to the teeth has been found to reduce caries. However, the cost in professional time is rather high and limits this method on a large-scale public health basis.

Endorsements

After a thorough examination of all scientific evidence relating to the safety, effectiveness, and practicability of fluoridation, the Public Health Service endorsed it in 1951. Since that time many communities throughout the Nation have instituted fluoridation programs. Careful study of their experience with this measure plus continuing scientific research have provided additional evidence supporting fluoridation. The literature about the relation of fluorides to health now exceeds 8,500 references.

In this country fluoridation is approved by every major scientific and professional organization having competence in the field. It has also been approved by the World Health Or-

ganization, by professional and scientific associations in many foreign countries, and by responsible health officials throughout the world.

Present Status

Today more than 42 million people in the United States (or about 1 in every 3 persons provided water by community water supplies) are drinking water containing the minimum or higher level of fluoride recommended. Of these, 35 million in 1,778 communities are supplied water in which the fluoride level is controlled, and 7 million in 1,903 places use water naturally containing 0.7 ppm or more fluoride. Since 1950, the number of persons provided with fluoridated water in this country has increased by about 34 million. Fluoridation programs are also in operation in 20 foreign countries.

Water engineers report that the addition of fluorides to public water supplies is similar to chlorination and other procedures widely employed in waterworks practice. Fluoridation presents no administrative, technical, or industrial problems of any consequence. Presently, five fluoride compounds are used: sodium fluoride, sodium silicofluoride, hydrofluosilicic acid, ammonium silicofluorides, and fluorspar. Costs of fluoridation vary according to the amount and kind of compound required, but the average cost is 10 cents a year per person. A device developed by Public Health Service engineers now enables communities to use fluorspar, further reducing the costs by two-thirds.

Current investigations by the Public Health Service related to fluoridation include continuing evaluation of community water fluoridation programs; improving technical, control, and testing procedures; developing individual fluoridators for homes and schools in rural areas; testing various fluorides for a more effective agent to be applied topically to the teeth; and developing practical methods for removing excessive fluorides from water supplies.

Decline in Community Acceptance

At first glance, the acceptance of fluoridation during the last 8 years appears satisfactory.

A closer look, however, reveals that most of the gain has been made in the larger cities. Sixty-six percent of the Nation's cities with populations of more than a half million, and 32 percent of the cities with populations between 10,000 and 500,000 have fluoridation programs. By contrast, only 17 percent of those communities having populations of 2,500 to 10,000 and 5 percent of communities with populations of less than 2,500 have such programs. Consequently, most of the people benefiting from this measure live in the larger cities.

Of special concern is the steady decline in the rate of community acceptance in the past 6 years. Community acceptance proceeded slowly from 1945 to 1950, the early years of the demonstration studies. By 1952, however, most scientific and professional groups had examined the evidence and formally approved water fluoridation. That same year 243 communities instituted fluoridation programs. The following year, 1953, was the peak year during which 378 separate communities adopted fluoridation. Since 1953 the number of separate communities starting fluoridation programs has declined. Only 145 places began fluoridation programs in 1958. Moreover, the number of communities which discontinued fluoridation programs in the past 5 years has steadily increased.

The question may well be raised as to why this slow rate of acceptance has occurred, and what steps need to be taken to accelerate the utilization of this measure for the improvement of our Nation's health. Obviously, the big job is yet to be done.

There are two circumstances which explain the initial acceleration and subsequent slowdown in community acceptance of fluoridation. During the earlier years (1945-52) fluoridation was instituted by governing bodies that were convinced by the weight of scientific evidence. Only occasional objections were voiced against the measure. By late 1952, however, the formerly disorganized and sporadic opponents joined forces, forming two national organizations specifically to oppose fluoridation. As a result, the opponents obtained substantial resources; and, by employing a wide variety of tactics, they have been able to thwart the institution of fluoridation.

The other circumstance may be that the com-

munities which normally accept new health measures readily had done so by late 1952. Thereafter the rate of acceptance may have declined somewhat because it is more difficult to get acceptance by the remaining communities.

Organized Opposition

Four different groups oppose fluoridation—those who oppose it on principle; those in whom the measure arouses personal anxieties; those who acquire status, political gain, or personal profit; and those who are uninformed. Opponents, mostly laymen, but also including a few scientists, physicians, and dentists, carry on a nationwide campaign through their two national organizations in the United States.

It is quite evident that a relatively few people can create doubt and fear in many others who otherwise would accept the advice of competent experts. Antifluoridationists publish a monthly newspaper and submit articles to medical journals, popular magazines with national circulations, and newspapers. A book, "The American Fluoridation Experiment," has become the opposition textbook and is widely distributed. Opponents have delayed fluoridation by numerous injunctions. They have filed suits unsuccessfully in more than a dozen State courts. Two cases were even appealed to the U.S. Supreme Court where they were dismissed. Opponents send a steady flow of letters and literature to Federal, State, and local officials. As one after another irresponsible claim is refuted, opponents change their attack. Local merchants and editors frequently are intimidated by threats and harassing telephone calls. Proponents are abused by smear tactics and public heckling, and they and their families are threatened with physical harm. It is noteworthy that opposition in many communities comes in the first instance, not from residents of the city considering fluoridation, but from elsewhere.

Objections to fluoridation, however unfounded or unrealistic, strike a sympathetic chord in a sizable number of people. Continuous sensational assertions of an emotional type have far more effect on public opinion than the precise correct statements of scientists. Furthermore, some people, once persuaded to op-

pose something they do not understand, seldom change their attitude.

From coast to coast, numerous strife-torn communities, confused and divided over a word that was not even in their vocabulary a generation ago, can attest to the effectiveness of the antifluoridation campaign. The referendum is a particularly effective framework in which to oppose fluoridation. Irresponsible statements, misleading and horrifying, have succeeded in defeating fluoridation by referendums in Seattle, Wash., San Diego, Calif., Birmingham, Ala., Columbus, Ohio, and well over 230 other communities. By referendums, twice as many communities have rejected fluoridation as have adopted it.

Several factors contribute to the problem. Tooth decay is not a dramatic, infectious, crippling, or killing disease. Most people have learned to live with their dental problems and do not regard them as sufficiently serious to require treatment. The scientific arguments for fluoridation are not simple; fluoridation cannot compare with the drama of the wonder drugs, and the benefits to be derived from it cannot be observed for more than a decade—even then they are not obvious.

Viewed in historical perspective, the opposition to fluoridation has been quite similar to that which arose when other public health measures were introduced, particularly chlorination, pasteurization, immunization, and vaccination. The psychological bases for objecting to fluoridation are the same: (a) fear of being physiologically injured by a potentially noxious agent; (b) ethical aspects, with special concerns about invasion of human rights; (c) rejection of a new discovery that conflicts with entrenched beliefs; and (d) resistance to change.

The crux of the problem is that a relatively few people are blocking the progress of an approved health measure. By so doing they are not only withholding health benefits from a large portion of the population, especially children, but they are perpetuating a disease that seriously impairs the Nation's health, manpower, and economic resources. If dental decay were a direct cause of death, there would be little doubt of the widespread adoption of water fluoridation.

Statements on Proposed Alternatives to Fluoridation of Water Supplies

Tablets

"An extensive program has been instituted in Switzerland (1) in an attempt to control dental caries through the administration of fluoride tablets to school children. Held and Piquet (2) in a preliminary report of a study of 6-year-old school children, which continued 3 years, reported that compressed sodium fluoride tablets were effective in reducing the incidence of dental caries. With the report of positive results, the practice has spread rapidly, and approximately 500 Swiss communities are using this method of caries prevention (1). Apparently the tablets are distributed in the primary schools; the method of administration, if any, of the fluorine prophylaxis to preschool children and infants is not known. A recent communication from H. J. Schmidt indicates that prophylaxis by means of fluoride tablets is also being administered in the state of Hessen, Germany.

"Use of fluoride tablets has been limited in the United States. Dietz (3) has reported a study involving a small number of children. Positive results were reported. Bibby, Wilkins, and Witol (4) state that the use of fluoride lozenges may contribute to the control of dental caries, and that the effects are probably the result of fluorine acting on external surfaces of the teeth. The number of persons observed was relatively small and the duration of the study only 12 to 14 months.

"In discussing the question of using fluoride tablets beginning at 5 or 6 years of age (first school year), certain presumptive evidence from fluoridation studies might be kept in mind. From the behavior of the results that A. L. Russell (personal communication, 1955) is obtaining in his studies in Montgomery and Prince Georges Counties, Md., the ingestion of fluorides after the period of tooth formation may not give the same protective effect as ingestion during the period of calcification. Effects observed in the earlier fluoridation

studies support this inference; for example, the present dental caries prevalence rates in the Grand Rapids children who were 6 years old when fluoridation started (now 16 years old) as compared to those of the 16-year-old, Aurora, Ill., children who have used fluoride water all during their lifetime. It would seem logical, in the light of present evidence, to assume that an appreciable measure of protection would be lost if fluoride tablets were used by children only after starting to school, even if fluoride tablets are theoretically as effective as fluoride-bearing water.

"Another point to be borne in mind is that from the standpoint of effective public health application, the individual administration of fluoride tablets presents more difficulties than a broad community action, such as fluoridation. As a large portion of a child's permanent teeth are calcified prior to 6 years of age (normal time to enter primary school), a high degree of intelligent participation on the part of each mother, an alertness against waning interest, and a daily constancy of purpose measurable in years, is essential. The health education question posed by the tablet method of application becomes highly important if any degree of success is to be attained.

"In the light of present available evidence, prophylaxis by means of fluoride tablets cannot be evaluated properly until carefully controlled studies, including adequate numbers of children and observed over the necessary number of years, are available. At the present time, such studies are not available. From the standpoint of theoretical physiology, there would seem no reason why fluoride tablets should not be effective, providing some method can be found to ensure their conscientious daily consumption, at least over the period of tooth calcification. Because of the health education essential for their success it might be well, for the present, to limit the use of fluoride tablets in the control of dental caries to prescription by the dentist.

munities which normally accept new health measures readily had done so by late 1952. Thereafter the rate of acceptance may have declined somewhat because it is more difficult to get acceptance by the remaining communities.

Organized Opposition

Four different groups oppose fluoridation—those who oppose it on principle; those in whom the measure arouses personal anxieties; those who acquire status, political gain, or personal profit; and those who are uninformed. Opponents, mostly laymen, but also including a few scientists, physicians, and dentists, carry on a nationwide campaign through their two national organizations in the United States.

It is quite evident that a relatively few people can create doubt and fear in many others who otherwise would accept the advice of competent experts. Antifluoridationists publish a monthly newspaper and submit articles to medical journals, popular magazines with national circulations, and newspapers. A book, "The American Fluoridation Experiment," has become the opposition textbook and is widely distributed. Opponents have delayed fluoridation by numerous injunctions. They have filed suits unsuccessfully in more than a dozen State courts. Two cases were even appealed to the U.S. Supreme Court where they were dismissed. Opponents send a steady flow of letters and literature to Federal, State, and local officials. As one after another irresponsible claim is refuted, opponents change their attack. Local merchants and editors frequently are intimidated by threats and harassing telephone calls. Proponents are abused by smear tactics and public heckling, and they and their families are threatened with physical harm. It is noteworthy that opposition in many communities comes in the first instance, not from residents of the city considering fluoridation, but from elsewhere.

Objections to fluoridation, however unfounded or unrealistic, strike a sympathetic chord in a sizable number of people. Continuous sensational assertions of an emotional type have far more effect on public opinion than the precise correct statements of scientists. Furthermore, some people, once persuaded to op-

pose something they do not understand, seldom change their attitude.

From coast to coast, numerous strife-torn communities, confused and divided over a word that was not even in their vocabulary a generation ago, can attest to the effectiveness of the antifluoridation campaign. The referendum is a particularly effective framework in which to oppose fluoridation. Irresponsible statements, misleading and horrifying, have succeeded in defeating fluoridation by referendums in Seattle, Wash., San Diego, Calif., Birmingham, Ala., Columbus, Ohio, and well over 230 other communities. By referendums, twice as many communities have rejected fluoridation as have adopted it.

Several factors contribute to the problem. Tooth decay is not a dramatic, infectious, crippling, or killing disease. Most people have learned to live with their dental problems and do not regard them as sufficiently serious to require treatment. The scientific arguments for fluoridation are not simple; fluoridation cannot compare with the drama of the wonder drugs, and the benefits to be derived from it cannot be observed for more than a decade—even then they are not obvious.

Viewed in historical perspective, the opposition to fluoridation has been quite similar to that which arose when other public health measures were introduced, particularly chlorination, pasteurization, immunization, and vaccination. The crux of the problem is that a relatively few people are blocking the progress of an approved health measure. By so doing they are not only withholding health benefits from a large portion of the population, especially children, but they are perpetuating a disease that seriously impairs the Nation's health, manpower, and economic resources. If dental decay were a direct cause of death, there would be little doubt of the widespread adoption of water fluoridation.

supply is fluoridated or already contains sufficient fluorides.

4. The practical difficulties and hazards that would exist, both in controlling the rate of application and in testing the amount of fluorides added to relatively small volumes of milk by the large number of individual milk plants that might adopt this practice. From an administrative standpoint, the fluoridation of milk would spread the responsibility for control, and would necessitate the introduction of a complicated system of supervision.

5. The likelihood that only a portion of the milk supply would be fluoridated in a given market, resulting in a lack of uniform distribution. This would reduce the benefits to be obtained by the community as a whole. From this point of view, it would appear that water is a much better vehicle."

—*U.S. Public Health Service. The fluoridation of milk—a statement of policy.*

"Technical problems are such that representatives of the milk industry have resisted the idea of fluoridating milk in the past. It has been estimated that fluoridation will add 1 cent per quart to the milk price. Health department supervision of milk fluoridation would be costly. To provide adequate checking, 25,000 samples per year would need to be tested in the laboratory. The health department would have to construct adequate facilities for the testing program and enlarge the staff to perform the work. It is estimated that the annual cost exclusive of facilities would be \$294,800 for performance of tests by official methods of analysis. The cost of fluoridated milk for school children only in New York City is estimated at \$2,140,000, or \$2.14 per person."

—*From Report to the Mayor on Fluoridation for New York City, by the Board of Health, City of New York, October 24, 1955, p. 38.*

"In regard to the distribution [of fluoridated milk], the committee feels that there would be a lack of uniformity of intake in various parts of the country and that small farms and dairies in rural districts would have problems in controlling the addition of fluoride to small quantities of milk. Furthermore, the intake of milk during the first year of life would depend on

the extent to which the babies were breast fed. Human milk contains only traces of fluoride, the highest concentration found in our study (Hodge and associates, unpublished data) being 0.09 ppm."

—*The problem of providing optimum fluoride intake for prevention of dental caries. National Academy of Sciences-National Research Council, Publication 294, November 1953, p. 12.*

Bread

"Common foods suitable as carriers for fluoride, must above all meet the requirements of food technology for easy handling and mixing. Flour, as an example, may be considered a feasible vehicle from the standpoint of stability and the technology of distribution of the fluoride uniformly throughout the food. According to the study of Widdowson, the consumption of cereal increased from approximately 2 ounces per individual per day in the 1-year-old group to an average of 6 ounces in the 12-year-old. The consumption of bread showed roughly the same quantitative increase with age. Consequently, the average intake of fluoride, if added to flour, bread, or cereal, would come near to the desired increase with age from infancy to adolescence. The average daily consumption of flour in this country is estimated to be similar, or about 6½ ounces per individual per day in the adult. Considering the desirable intake of fluoride in older children as 1 mg. per day, the approximate amount of fluoride to be incorporated in the flour could be calculated. However, we have already referred to English observations suggesting that there are marked individual variations within single age groups in the consumption of bread. In addition, it is believed, for lack of exact data, that in the United States bread would not be used to a great extent in infancy during the early stage of tooth development."

—*The problem of providing optimum fluoride intake for prevention of dental caries. National Academy of Sciences-National Research Council, Publication 294, November 1953, p. 11.*

Salt

"No exact information has been obtained with regard to the consumption of salt in various age

When all considerations are weighed, it would seem that in a community having a public water supply, the most economical and efficient manner of applying the fluorine prophylaxis to the greatest number of people is through fluoridation of the domestic water."

—H. Trendley Dean. *Fluorine in the control of dental caries. Journal of the American Dental Association*, vol. 52, January 1956, pp. 7-8.

"The preparation of fluoridated water at home by adding fluoride tablets to tapwater would be less expensive than the purchase of bottled water, but much more costly than communally fluoridated water. However, the proper preparation of such water in the home presents a very difficult problem of regulation. The problem is not merely one of assuring the addition of the proper amount of fluoride but also of proper mixing of the solution. An additional disadvantage of both alternative water procedures is that of inconvenience. It would be difficult to induce a high proportion of housewives and certainly of children to get their drinking and cooking water from a bottle rather than from the convenient sink tap.

"The daily consumption of tablets likewise raises questions of effectiveness and practicality. In the hands of trained personnel at the water treatment plant fluoride levels can be precisely controlled. But experience with other home remedies—even the aspirin tablet—prompts caution. The philosophy that 'if one tablet is good, two are better' may produce harm. A child's accidental ingestion of a large number of tablets is a great hazard from the viewpoint of those familiar with accidents in the home."

—From *Report to the Mayor on Fluoridation for New York City*, by the Board of Health, City of New York, October 24, 1955, pp. 33-34.

Bottled Water

"The process of preparing fluoridated water to be distributed in the same manner as bottled water involves the installation of equipment in one or more bottling plants and distribution to those who are willing to buy it. It is unlikely that a bottling plant would install the same kind of equipment that would be used in water treatment. One method that might be used is

that of dissolving tablets containing fluoride ion in the water. A number of technical problems are introduced. The water would have to be tested for fluoride ion by the health department and bottled water companies would have to employ technical staff to supervise treatment procedures.

"Persons using the water must pay for the water as well as the fluoride ion. It is estimated that bottled fluoride water would cost 5 cents per day per person using it, or about \$18.25 per year per person.

"Minimum health department supervision of bottled water fluoridation is estimated at \$20,000 per year. The minimum estimate of the cost of bottled fluoride water at present prices would be not less than \$18.25 per person per year. Such a price is of course prohibitive, and it is doubtful if many adults or children would have the benefit of fluoride water if such a fluoridation program were instituted."

—From *Report to the Mayor on Fluoridation for New York City*, by the Board of Health, New York City, October 24, 1955, p. 37.

Milk

"The Public Health Service does not favor the addition of fluorides to milk for the purpose of prevention of dental caries. The reasons for this position are as follows:

1. It is not known whether the addition of fluorides to milk is effective in preventing tooth decay, although it is known that such addition is effective in water. Further studies of this matter are indicated.

2. The individual consumption of milk by children varies considerably more than their water intake. For economic and other reasons, a considerable number of children in some age groups consume little or no milk. Furthermore, the use of fluorides in milk has not been investigated. On the other hand, we do know, on the basis of examination of many thousands of children who have consumed water varying in fluoride concentration, the amount of fluorides which must be added to water to be effective.

3. The possibility that fluoridation of milk may be harmful in an area where the water

supply is fluoridated or already contains sufficient fluorides.

4. The practical difficulties and hazards that would exist, both in controlling the rate of application and in testing the amount of fluorides added to relatively small volumes of milk by the large number of individual milk plants that might adopt this practice. From an administrative standpoint, the fluoridation of milk would spread the responsibility for control, and would necessitate the introduction of a complicated system of supervision.

5. The likelihood that only a portion of the milk supply would be fluoridated in a given market, resulting in a lack of uniform distribution. This would reduce the benefits to be obtained by the community as a whole. From this point of view, it would appear that water is a much better vehicle."

—U.S. Public Health Service. *The fluoridation of milk—a statement of policy.*

"Technical problems are such that representatives of the milk industry have resisted the idea of fluoridating milk in the past. It has been estimated that fluoridation will add 1 cent per quart to the milk price. Health department supervision of milk fluoridation would be costly. To provide adequate checking, 25,000 samples per year would need to be tested in the laboratory. The health department would have to construct adequate facilities for the testing program and enlarge the staff to perform the work. It is estimated that the annual cost exclusive of facilities would be \$294,800 for performance of tests by official methods of analysis. The cost of fluoridated milk for school children only in New York City is estimated at \$2,140,000, or \$2.14 per person."

—From *Report to the Mayor on Fluoridation for New York City, by the Board of Health, City of New York, October 24, 1955, p. 38.*

"In regard to the distribution [of fluoridated milk], the committee feels that there would be a lack of uniformity of intake in various parts of the country and that small farms and dairies in rural districts would have problems in controlling the addition of fluoride to small quantities of milk. Furthermore, the intake of milk during the first year of life would depend on

the extent to which the babies were breast fed. Human milk contains only traces of fluoride, the highest concentration found in our study (Hodge and associates, unpublished data) being 0.09 ppm."

—*The problem of providing optimum fluoride intake for prevention of dental caries. National Academy of Sciences-National Research Council, Publication 294, November 1953, p. 12.*

Bread

"Common foods suitable as carriers for fluoride, must above all meet the requirements of food technology for easy handling and mixing. Flour, as an example, may be considered a feasible vehicle from the standpoint of stability and the technology of distribution of the fluoride uniformly throughout the food. According to the study of Widdowson, the consumption of cereal increased from approximately 2 ounces per individual per day in the 1-year-old group to an average of 6 ounces in the 12-year-old. The consumption of bread showed roughly the same quantitative increase with age. Consequently, the average intake of fluoride, if added to flour, bread, or cereal, would come near to the desired increase with age from infancy to adolescence. The average daily consumption of flour in this country is estimated to be similar, or about 6½ ounces per individual per day in the adult. Considering the desirable intake of fluoride in older children as 1 mg. per day, the approximate amount of fluoride to be incorporated in the flour could be calculated. However, we have already referred to English observations suggesting that there are marked individual variations within single age groups in the consumption of bread. In addition, it is believed, for lack of exact data, that in the United States bread would not be used to a great extent in infancy during the early stage of tooth development."

—*The problem of providing optimum fluoride intake for prevention of dental caries. National Academy of Sciences-National Research Council, Publication 294, November 1953, p. 11.*

Salt

"No exact information has been obtained with regard to the consumption of salt in various age

groups. It is not even certain that this vehicle would be practical from a technical standpoint; it would have to be determined, for instance, whether the addition of sodium fluoride would be uniform throughout and whether it would affect unfavorably the anti-hygroscopic property of the product. While the daily consumption would have to be determined more exactly, there are doubts as to whether this vehicle would serve the purpose for infants and young children."

—*The problem of providing optimum fluoride intake for prevention of dental caries. National Academy of Sciences-National Research Council, Publication 294, November 1953, p. 12.*

Summarization

"Various vehicles have been proposed for the systemic administration of fluoride in regions where water fluoridation cannot be applied. The most important of these vehicles seem to be milk, table salt, and fluoride tablets which are now all being tested. Milk might be a possible alternative vehicle in countries with a universal milk consumption by the children, while salt might be possible for regions with a low or irregular milk consumption.

"At present, the value of milk and salt for fluoride administration cannot be compared with that of drinking water, since the evidence in favor of the first two vehicles is incomplete; in particular, there is a total lack of clinical

evidence of their effectiveness. On the other hand, tablets have been shown to have some positive effect, although the experiments with tablets have been performed for a much shorter time and on a much smaller scale than drinking water fluoridation.

"Continued research on these fluoridation methods should be encouraged. If their effectiveness, practicability, and safety of application can be satisfactorily demonstrated, they may become very valuable in regions where water fluoridation is impossible."

—*Expert Committee on Water Fluoridation, First Report. World Health Organization Technical Report Series No. 146, Geneva 1958, p. 19.*

Drinking Water Standards To Be Revised

An advisory committee of physicians, scientists, engineers, and administrators has been appointed to consider revision of the Public Health Service Drinking Water Standards. At its first meeting, March 24-25, 1959, special attention was given to limits for nonliving contaminants such as radionuclides and synthetic organics.

The Drinking Water Standards, first formulated 45 years ago and last revised in 1946, were originally applicable only to water used on interstate carriers. This is still their only legal basis. However, State health departments, the American Water Works Association, and the Armed Forces have accepted them as standards for public water supplies.

Education, and Welfare, April 7, 1959*

Indian Health

ONE of the Nation's most dramatic health stories of our time has been unfolding quietly and steadily among American Indians and Alaska natives.

I have received from Surgeon General Leroy E. Burney a report of recent progress in the Indian health program covering improvements in health and medical services to the 385,000 American Indian and Alaska native beneficiaries. This report traces health trends since 1954, immediately prior to the transfer of the program to the Public Health Service in 1955, through facts and figures available in the closing quarter of 1958. Here are some of the highlights:

- Tuberculosis, once the leading cause of death among Indians and Alaska natives, dropped a full 40 percent among the Indians in the 4-year period ended with 1957. Among Alaska natives, the decrease was even greater—63 percent in the same period. This disease now ranks as the eighth cause of death among Indians, and fifth among Alaska natives.

- New cases of tuberculosis have dropped 25 percent among Indians and about 33 percent among Alaska natives.

- The Indian infant death rate has been reduced by 12 percent.

- The Indian death rate from diseases of the stomach and intestines came down by 26 percent.

This is the first report of a series to be issued regularly so that full, current information on the progress of health services to Indians and Alaska natives may be constantly available.

In calling attention to progress since 1954, neither Dr. Burney nor I wish to give the impression that this country's Indian health problems are solved. This is far from true,

even with respect to tuberculosis. That disease still claims nearly four times more lives among American Indians than among the Nation's general population, and upwards of eight times more Indians contract tuberculosis. The tuberculosis death rate among Alaska natives is more than 10 times greater than the national average.

Health problems among American Indians and Alaska natives still are unique and severe. Language differences combined with limited understanding by Indians of health and disease concepts still constitute obstacles of considerable magnitude. Geographic and cultural isolation on some 250 Federal Indian reservations and in hundreds of native villages in Alaska, combined with an extremely low economic level, are serious handicaps in the provision of services.

The health program operates over tremendous areas in 25 States, including Alaska. Its hospital at Point Barrow, above the Arctic Circle, is the most northerly in the world. In this area, the Public Health Service has medical personnel who drive their own dogsleds and fly their own airplanes. The first operation ever performed in Alaska involving the transplanting of a cornea was on a 16-year-old Eskimo girl in the Public Health Service hospital at Anchorage in December 1958.

Distances, population dispersion, and absence of local water supplies pose severe obstacles for doctors, nurses, health educators, and sanitation personnel in the southwest. One Public Health Service dental officer travels 10,000 miles a year treating his patients on the vast Navajo reservation, which covers an area the size of West Virginia. Construction of an urgently needed new hospital for the Papagos

on the Arizona desert was delayed for months because of difficulties in locating a water supply.

Gross and widespread environmental sanitation problems—notably lack of safe water supply and overcrowded and inadequate housing—persist as the allies of excessive disease rates. These are problems which the Indians are generally unable to correct within their own economic resources. The task ahead is still enormous.

Substantial increases in funds for Indian health during recent years have enabled the Public Health Service to make inroads against critical disease problems. Trained professional staff members, so vital to the success of a direct service operation such as the Indian health program, have been substantially increased in number. A good start has been made in eliminating the generally unsatisfactory condition of Indian health facilities and the shortage of modern medical equipment.

Notable progress also has been made against trachoma, the infectious eye disease which still exists in this country among Indians. Dr. Phillips Thygeson, internationally recognized

authority on this disease, serves as the Public Health Service's consultant in planning and developing trachoma control activities. His "Trachoma Manual and Atlas" published last year by the Service is, I am told, a valuable aid in the diagnosis and treatment of trachoma not only among Indians but in other countries where this disease is a major health problem.

Although Indian infant deaths dropped 12 percent in the 4 years ended with 1957, the Public Health Service recognizes that the present rate of 57 deaths per 1,000 live births is excessively high. Increasing numbers of Indian babies are born in the Service's Indian hospitals, and as a result the Indian infant death rate in the first month of life now compares favorably with that of the general population. However, because of unfavorable environment, Indian infants die at more than five times the rate for the population as a whole during the succeeding 11 months of life.

We will never be satisfied until the health of the Indians is fully comparable with that of most Americans. It is our aim not only to hold present gains but to increase our efforts in this field.

New Reports on Death Rates

A new series of 62 reports presenting age-specific and age-adjusted death rates is being released by the National Office of Vital Statistics, Public Health Service. The series, Vital Statistics—Special Reports Volume 49, is entitled "Death Rates for Selected Causes by Age, Color, and Sex: United States and Each State."

These reports include both age-adjusted and age-specific rates for the average of the 3 years 1949, 1950, and 1951.

With the exception of No. 1, which summarizes data on death from all causes, each number contains data for a single cause of death or group of related causes. The reports follow the classifications in the "Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death." Thirty of the series have already been released, and the remainder are scheduled for publication during 1959.

Copies are available from National Office of Vital Statistics, Public Health Service, Washington 25, D.C.

Each nation in the Western Hemisphere has a concern with childhood accidents, which vary in nature according to geography, technology, and custom.

Accident Prevention in Childhood

JAMES L. GODDARD, M.D., M.P.H.

ACCIDENTS are the leading cause of death in children 5 to 14 years of age in 13 countries of the Western Hemisphere. If trends of the past two decades continue, we shall find within 20 years that in many nations of the Americas accidents will constitute the leading cause of death for all age groups 1 to 15 years.

Granted the urgency of organizing a broad attack on the childhood accident problem, how shall we proceed?

Once the established techniques of factfinding and casefinding have defined the task of preventing childhood accidents in any given area or community, the procedure eventually emerges.

Each specific accident hazard requires specific methods of prevention. The traffic-filled street in New York or Rio de Janeiro, the Texas ranch, or the Peruvian mountain village contains unique hazards in a unique setting, requiring its own preventive program.

Mortality and Morbidity

Nothing illustrates more clearly the geographic variation in the relative significance of accidents to children than an analysis of mortality tables for the 17 countries of the Americas and Puerto Rico, Jamaica, and Trinidad. Data on the five principal causes of death, with rates per 100,000 population, for children in

two age groups, 1-4 and 5-14 years, for 1956 are given in figures 1 and 2. In considering death rates in these two age groups, it should be noted that the rates are much lower for the age period 5-14 years than for the age period 1-4 years in many countries where disease still takes a high toll.

Only in the United States and Canada were accidents the leading cause of death in the 1-4 age group. In only eight of the remaining countries were accidents even listed among the five leading causes of death. In the 5-14 age group, however, accidents are the leading cause of death in two-thirds of the countries reporting, and only in Guatemala are accidents missing from the five chief causes of death. The highest rate given is for Ecuador, where the figure (39.7) is almost double the United States rate of 20.

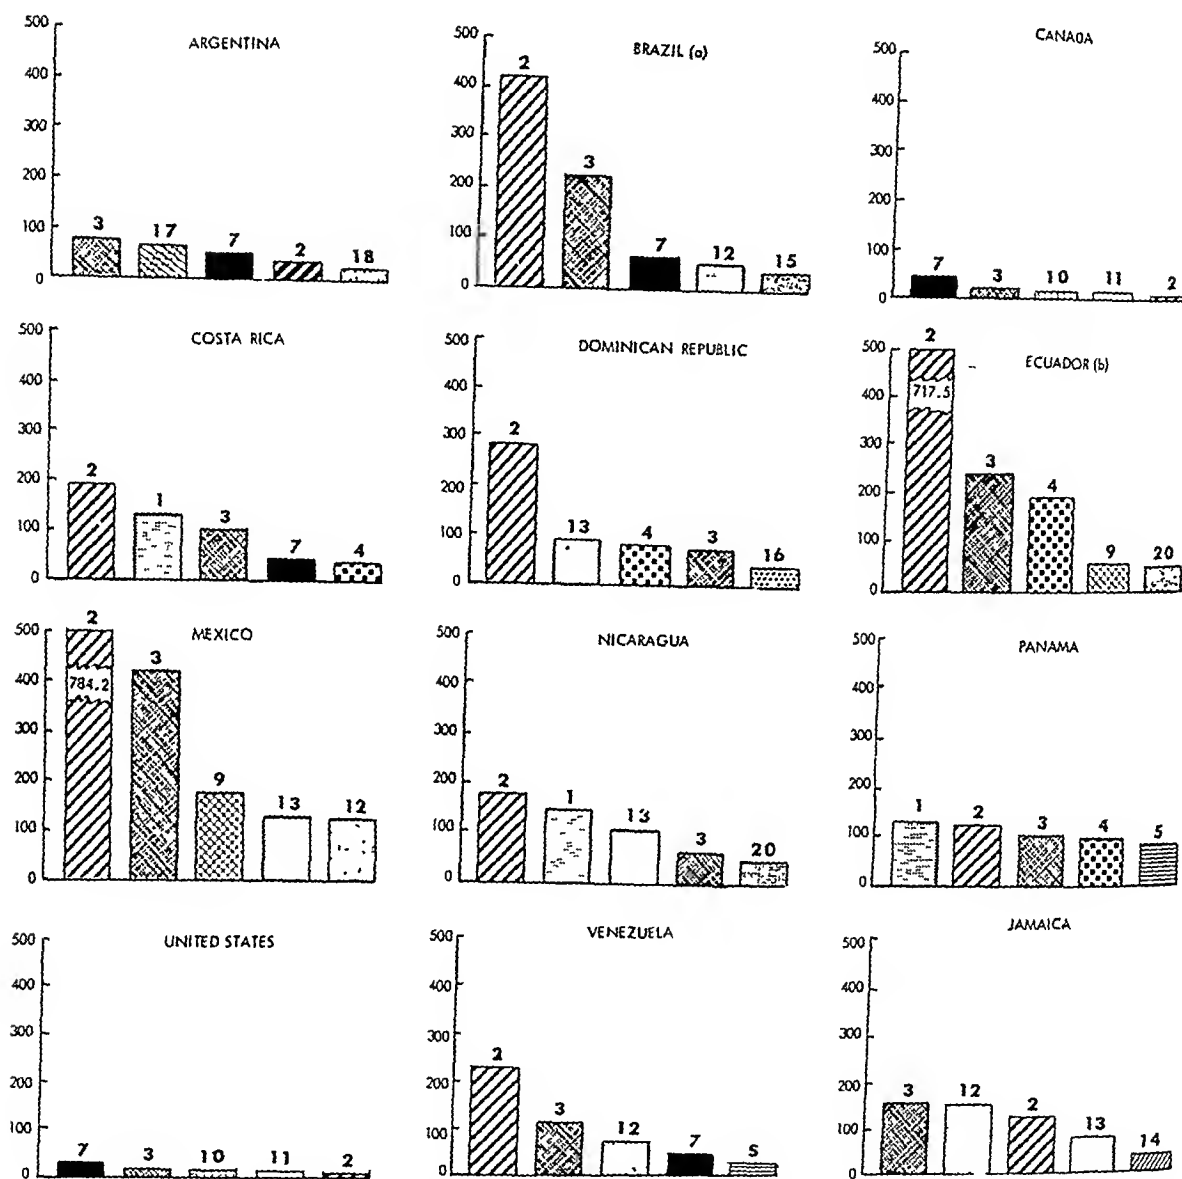

The California Health Survey of 1954-55 reveals that incidence of illness from accidents ranks second only to diseases of the respiratory system for children under 15 years of age (table 1).

For those who survive the common diseases of infancy and childhood, there is the ever-

Dr. Goddard is chief of the Accident Prevention Branch, Public Health Service. This article is based on a paper presented at the 15th Pan American Sanitary Conference held in San Juan, Puerto Rico, September-October 1958.

present threat of death or injury from accidents. This threat is both widespread and complex.

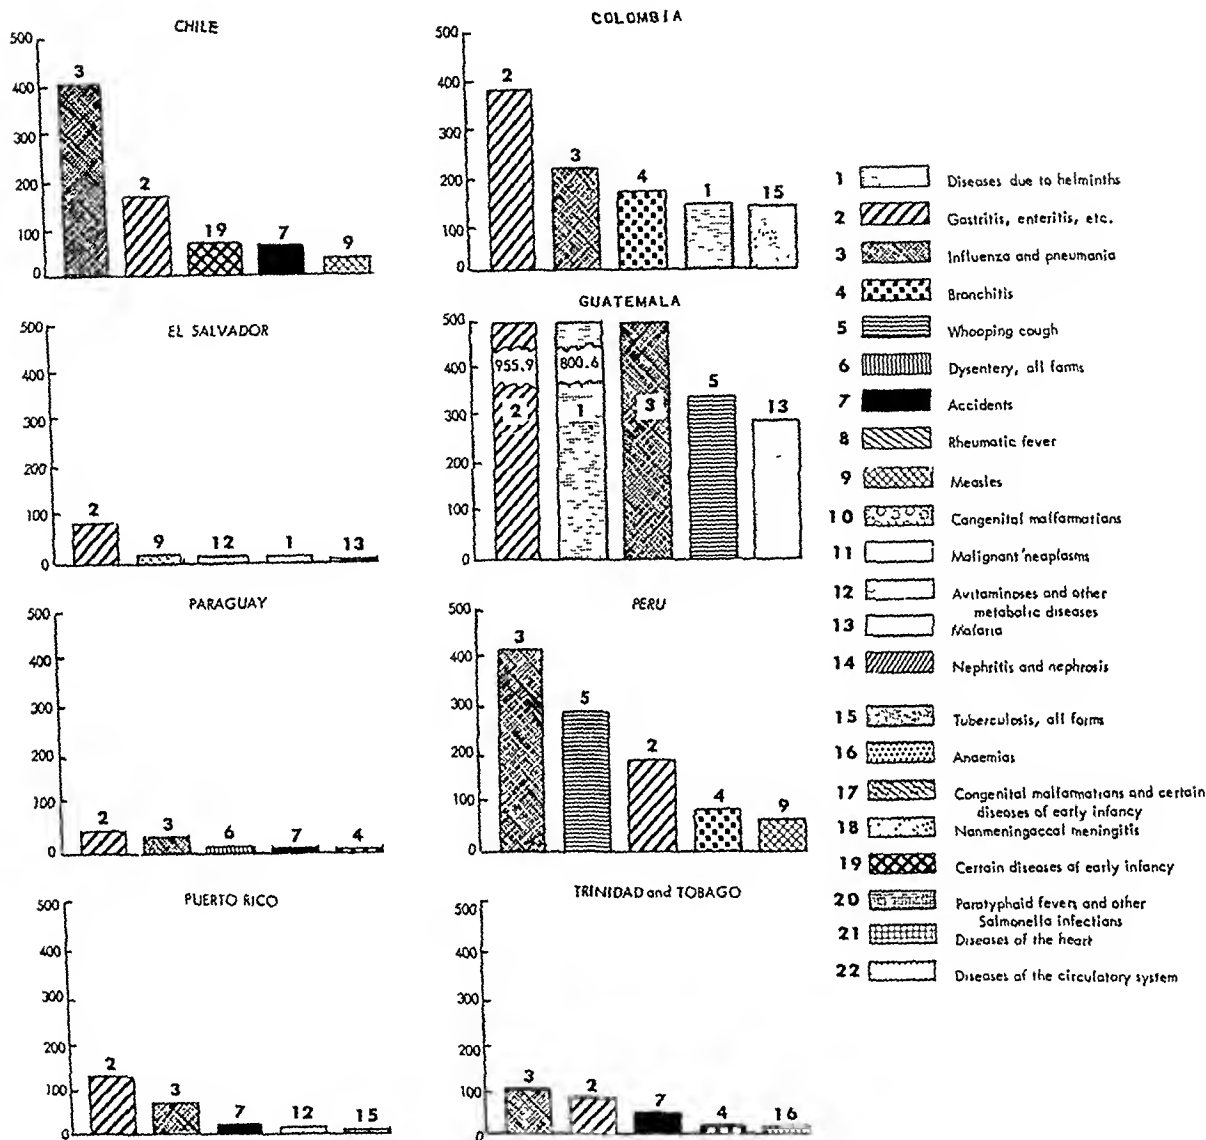

On the basis of the first 6 months' report of the National Health Survey in the United States, it is estimated that approximately 16 million children are injured each year, with the rate about twice as great in boys as in girls.

Of girls under 15 years of age, one child in three is injured each year, and most of them are injured in and around the home.

Throughout the Americas, frequently encountered causes of accidental death in children are motor vehicle accidents, drowning, burns, poisoning, falls, and bites from poisonous insects or snakes.

Figure 1. Principal causes of death among children 1-4 years of age in the Americas, 1956—Continued.

Rates per 100,000 population

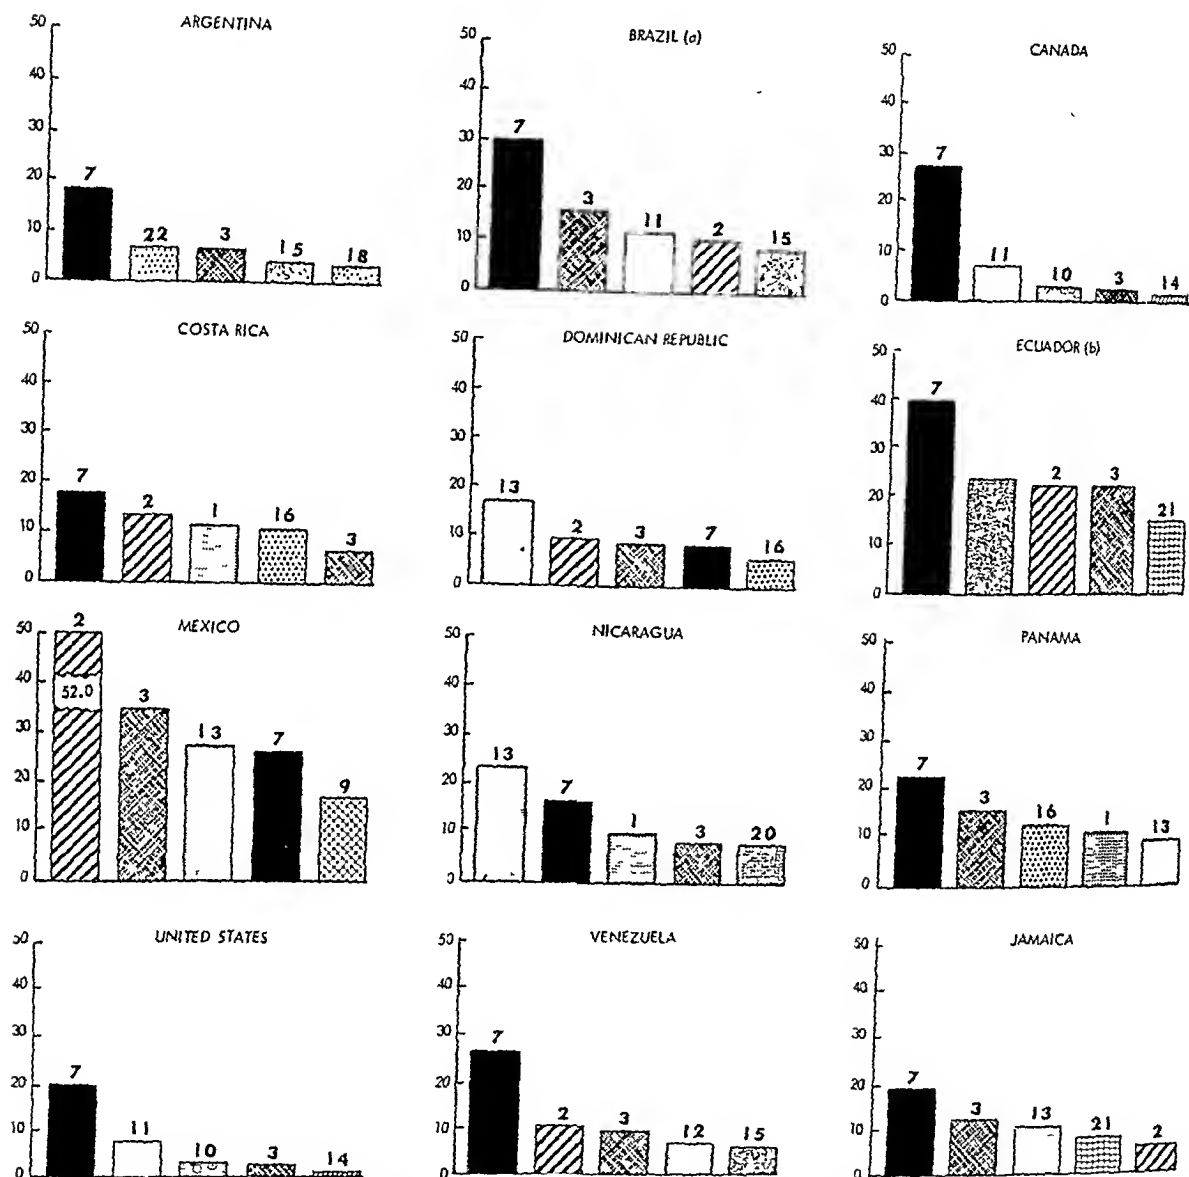

The number of reported deaths of children 1-4 and 5-14 years of age from accidents, with rates per 100,000 population, in the Americas is presented in table 2.

Analysis of specific causes of mortality for the United States and Venezuela reveals a greater number of both fatal and nonfatal injuries among boys. It is generally assumed that the growing boy is more active and more inclined to take risks than a girl of the same

age. There are also other striking differences. In the 5- to 14-year-old girls in Venezuela, for example, burns are the most frequent cause of accidental death. In boys of the same age, drowning is the most frequent cause, and burns rank fifth. Obviously such differences are related to exposure factors. The risk of drowning is greater for boys because more boys are exposed to the risk. Burns are more frequent for girls because they spend more time in the

home at this age, learning how to cook and, of special importance, wearing clothing more susceptible to fire hazards (table 3).

In Puerto Rico, a slightly different pattern is noted for the age group 1-4. Poisoning is the leading cause of accidental death, followed by burns, motor vehicle accidents, drowning, and falls.

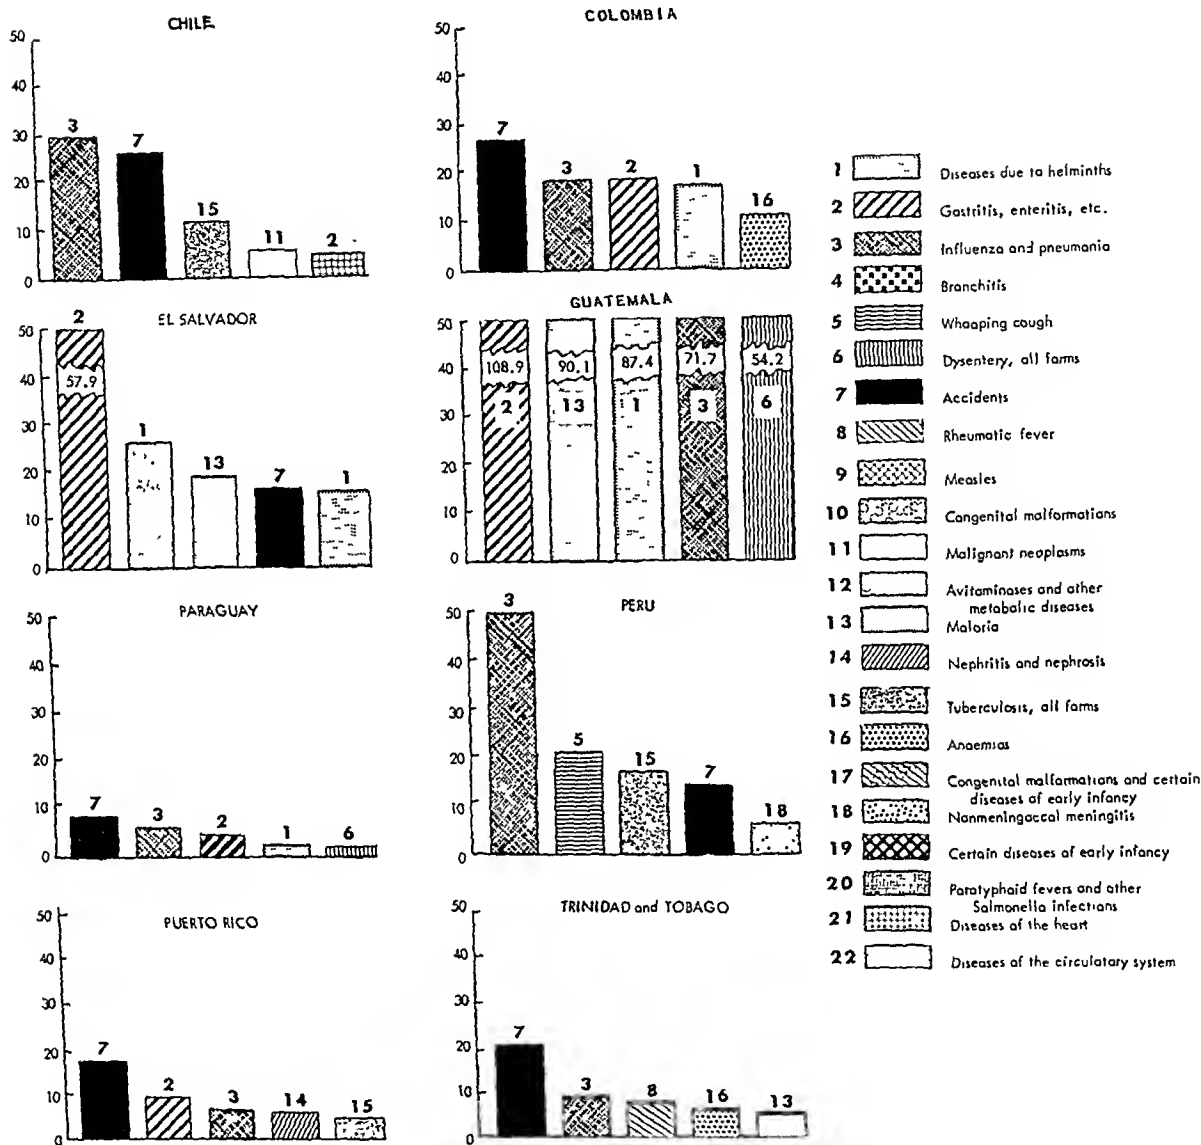

In Mexico, deaths from tetanus are frequent in the age group 5-14. Most cases of tetanus are preceded by an untreated injury, usually a laceration or puncture wound of the foot.

Poisonings

Accidental poisoning is a special threat, particularly to children under 2 years of age. The

Figure 2. Principal causes of death among children 5-14 years of age in the Americas, 1956—Continued.

Rates per 100,000 population

common agents responsible for fatalities in the United States are petroleum products, aspirin and salicylates, arsenical compounds, and lead and its compounds (table 4).

Central and South American countries also report that petroleum products and pesticides are frequently the cause of fatal poisonings.

Better definition of the problem of accidental poisoning is possible when hospitals and emergency centers keep simple but accurate records

of the causative agents. The experience of 23 poison control centers in the United States is summarized by type of substance in table 5.

In approximately 25 percent of those cases involving medicine, aspirin or other salicylates were ingested. Aspirin may not be quite so widely available elsewhere. In 230 poisoned patients seen in 1 year at a children's hospital in South America, only 2 had swallowed aspirin or salicylates. Petroleum products and bleach-

ing fluid were the two most frequent poisons reported by this institution.

Site of Accidents

Although detailed data on the sites of childhood accidents are not now available, preliminary analysis of the U.S. National Health Sur-

vey data for all age groups shows that 45 percent of all accidental injuries occur in the home, 30 percent in public places, 14 percent at work, and 10 percent on the highway. A study of accident cases treated in the emergency room of the municipal hospital in San Juan, Puerto Rico, had a somewhat similar pattern of results: 56 percent of all injuries were caused by home accidents, 34.5 percent were accidents at public places, 6 percent were motor vehicle accidents, and 3.5 percent were work accidents.

The use of a uniform accidental injury report, such as form PHS-2916, obtainable from the Accident Prevention Branch, Public Health Service, Washington 25, D.C., can provide a wealth of data in a short time. On the basis of data gathered, preventive measures can be designed to meet the specific preventive needs.

Causative Factors

Accident causation is beginning to inspire formal research programs of an increasingly elaborate nature. Almost every one of the physical, natural, and social sciences has something to contribute to our understanding of this problem.

There is some risk at this stage, therefore, of being overwhelmed by the complexity of re-

search needs or confused by the tremendous scope of research possibilities. Every aspect of the classic epidemiological trinity (host, agent, environment) undoubtedly contains secrets that will ultimately yield to study and enhance our understanding of accident causation.

To help define the child as an "accident host," clearly we need to learn as much as we can about his growth and development, about the relationship between his mental and physical condition and accidents, about his educational background and progress.

The "agent" in childhood accidents can be almost anything he contacts, and this group of causative factors must be studied in a systematic and specific way if even limited progress is to be made. The motor vehicle is a prime example of an accident agent that is readily identified and isolated for study. Specific toxic substances that cause accidental poisoning offer a similarly delimited field of study.

In general, advances will be achieved by careful pursuit of specific study goals.

The child's "environment," the third element in the epidemiological triad, is as small as the crib or as large as the whole community, depending upon the age of the child. Geography, climate, economics, sociology, even history and politics play a part in molding the child's environment and in creating the causative relationship between that environment and accidents.

Since space does not permit an exhaustive analysis of this multitude of causative factors, we must be content with calling attention to a few dynamic factors. Common to all accidents are the person and the environment; their respective susceptibility and potential; habits, attitudes, and patterns of operation; specific changes, events, or irregularities in the pattern; and the built-in protective factors or feedbacks which may affect or avert the trigger action.

"Accident susceptibility" is obviously strong in a child because this factor is conditioned by training, experience, and judgment. Also, such special physiological and mental factors as illness, emotional upsets, and the like may be expected to affect children even more drastically than adults.

Finally, the "unsafe act or trigger mechanism" is clearly illustrated when a child starts a fire while playing with matches, or swallows poison while in search of candy.

In short, close study of such dynamic factors will well repay all who are professionally or personally concerned with improved accident prevention techniques based on better understanding of the causative factors. These have been charted graphically (1).

Prevention

Effective programs for the prevention, control, and amelioration of the effects of childhood accidents will be achieved through definition of the problem, formulation of specific hy-

potheses, testing and validation of the hypotheses, and translation of findings into action.

Since each accident results from a multiplicity of causative factors, no single solution can be expected. Diversities in cultural patterns, environmental conditions, and host factors necessitate careful selection of preventive activities.

Recommended activities are presented here with respect to principles of primary and secondary prevention. Many principles are, of course, applicable to both.

Primary Prevention

DEFINITION: There is a serious lack of sufficient data concerning accidents in childhood. Mortality and morbidity data, supplemented by special epidemiological studies, are the conventional sources of such information. In those Latin American countries where hospital and emergency services are provided by the government, data on accidental injuries may be obtained more readily than in voluntary or private institutions in Canada and the United States.

The minimum requirements of an accident reporting system include the following items for each injured patient: age, address, sex, race, marital status, occupation, hour, day, and date

of the accident, activity of the injured person at the time of the accident, nature of the injury, part of the body injured, severity or condition of the patient, name and address of

hospital and attending physician, and identification of the reporter.

Such data may be supplemented by analysis of death certificates. As programs are developed, routine specification on the death certificate of the type of fatal accident will be required.

The study of accidents by type (motor vehicle, falls, drowning, poisoning) and by type of injury (burns, lacerations, wounds) helps to suggest remedial measures. Defects in design of equipment or environmental hazards are frequently exposed by such analysis.

The redesign of refrigerators has been undertaken as a consequence of studies which revealed how many children crawled into discarded ice-boxes and were locked in.

The Cornell University Automotive Crash Injury Research project has profoundly influenced the design of passenger cars in the United States. The importance of the safety belt, validated by the Cornell studies, has altered the thinking of automotive safety engineers.

In a rural area of Georgia, an epidemiological study, inspired by the high incidence of burns reported among children there, formed the basis for a public health program to encourage the use of screens in front of fireplaces.

A Latin American analogy may be found in rural Chile where a brazier on the floor or the ground is the usual equipment for cooking. Protective devices, coupled with public health educational campaigns, could diminish this particular threat.

Knowledge of the relationship between childhood growth and development and accident patterns at different ages is necessary for educational programs directed to parents and schools. Longitudinal studies, while expensive and time consuming, will always be necessary.

The discriminate use of surveys on cross sections of population groups also helps in identifying and defining needs.

Retrospective study of deaths from accidents using supplemental death certificate forms has been made for years in different parts of the United States. The data have been useful in educating the public and in alerting health workers to hazards.

EDUCATION: Education is an elementary step

in accident prevention. In all fields, education progresses as distribution of information is fortified by experience.

Public health agencies need to be equipped with appropriate information and skills and motivated to accept educational responsibility when they attempt accident prevention.

The staff of a health agency may help other groups in the community and the citizens of the community themselves to acquire the necessary facts, equipment, and habits.

Physicians are one of the essential groups in accident prevention. They become excellent teachers. No medical practitioner speaks with more authority on safety for children than the pediatrician. Dr. Harry F. Dietrich defines the pediatrician's role as follows: (a) he must gain an enlightened awareness of the problem; (b) he must attempt to immunize his patients against serious accidents by providing parents with the theory of accident prevention and sufficient advice and encouragement to apply it; (c) he must alert the entire medical profession to the gravity and needs of the problem; and (d) he must enlist the aid of all available organizations in a continuous community and national campaign to prevent childhood accidents.

To this, perhaps, should be added: (e) he can alert us to new hazards; and (f) he can, by virtue of his detailed knowledge of the patterns of growth and development (both mental and physical), advise us as to the appropriateness and acceptability of preventive measures.

The school teacher is also important in accident prevention, as are all key leaders in the community.

It is the opportunity of the health agency to organize, stimulate, coordinate, inspire, and, sometimes, to finance cooperative efforts by all components of the society.

COORDINATION OF ACTIVITIES: The prevention of childhood accidents is of concern to many governmental agencies, traffic departments, and departments of education, health, social security, and labor. There is clearly a need for closer coordination between agencies engaged in this common effort. The role of the health agency in some instances actually may be limited to coordination; in other situations, the health department may play a direct role as well.

Coordination of health agency activities with educational departments is particularly important. The teaching of safe living has long been accepted as a responsibility of the schools in the Americas. In this work, health agencies assume a subordinate role, which initially may be limited to provision of suitable and up-to-date material. Later it may be possible to propose and assist in the development of preventive activities, such as swimming classes for preschool children as well as school children.

The frequency of traffic accidents suggests the need for coordination among several agencies. In countries such as the United States, Canada, and Mexico, where school-boy patrol activities have been initiated, liaison has been effected between the education and traffic departments. Extension and improvement of such programs is a goal of many health agencies.

Another civic activity is the development of adequate recreational facilities for children. A well-planned recreational program helps in keeping youngsters off the streets and away from traffic hazards. Again, such a program is seldom the direct responsibility of the health agency, but the demonstration of the need and recommendations for action could be.

LEGISLATION: In many instances, special hazards to children have been eliminated or controlled by the enactment and enforcement of legislation.

For example, in the United States flammable fabrics in children's clothing were brought under Federal regulation by act of Congress. The U.S. Congress has similarly acted to protect the public by legislation on the manufacture and sale of insecticides.

There are similar problems throughout the Americas, and as the reporting of injuries is improved, new hazards will be exposed which may warrant legislative control.

RESEARCH: There is obviously a need for developing and continuing operational research, as exemplified by surveys, analyses of hospital data, and analyses of death certificates. In addition, it is essential to initiate and expand basic research on human factors in accidents.

As has been mentioned, the epidemiological technique lends itself readily to studies in the accident field. McFarland, Gordon, and others

have pointed out the value of applying the principles of epidemiology to the study of accidents. Use of this technique already has led to reductions on a limited scale in certain types of injuries and deaths. In the past, these have been related usually to environmental factors or agent factors immediately associated with accidents.

One value of the epidemiological approach is that it facilitates appraisal of the data collection process. Epidemiological studies provide the basis for determining the value of data currently being collected, as well as pointing out the need for routine collection of additional data.

A second type of important research is related to improving education. Practically nothing has been done as yet to increase understanding of why people accept or reject recommendations for their own safety, or how various cultures are influenced in acceptance or rejection of specific practices.

A third type of essential research relates to improvement in treatment of injuries, through planned cooperative study involving several hospitals or treatment centers. One example is the study of kerosene poisoning now being conducted in the United States by the American Academy of Pediatrics, the American Public Health Association, and the Public Health Service. By pooling data from numerous hospitals, it is hoped that the question of the value of lavage in these cases can be reliably determined. Another such study could be carried out to compare the results from various treatments for serious burns.

The clinical study or case study will also be valuable in childhood accident prevention. The individual clinician, and particularly the pediatrician, can make a significant contribution through careful observation and analysis of patients seen day-to-day.

Secondary Prevention

Hazards to children are not wholly eradicable. Thus efforts must be directed not only toward a reduction of fatal accidents but also toward amelioration of the effects. Prevention of deaths from secondary causes and prevention or modification of disabilities are, there-

fore, aspects of the accident problem that cannot be neglected.

IMPROVEMENT OF EMERGENCY SERVICES: It was conclusively demonstrated during World War II that survival rates, length of hospitalization, and even the degree of disability could be related to the quality and distribution of emergency care.

The significance of careful handling of the victim, from the time of injury until definitive care begins, is appreciated by the medical profession. Unfortunately, their concern has not always been communicated to those responsible for emergency services.

There are three major elements involved in the care and transport of the injured: training of personnel, adequacy of equipment, and distribution of services in relation to population and the facilities used by the population.

Untrained ambulance attendants, inadequate equipment, speeding ambulances, lack of services in rural areas (as well as in some urban areas) are common throughout the Americas. Curry and Lyttle (2), in their excellent description of how one community was successful in overcoming these difficulties, provide a blueprint that can be adopted by others.

Adequate emergency room services are vital to secondary prevention. The controlling factors are again the training of personnel, the adequacy of equipment, and the availability of services. The special problem presented by accidental poisoning demonstrates the importance of recognizing these factors. Not only must the physician be capable of directing or providing general treatment for the child, he must, because of the multitude of possible toxic agents, be able to track down the specific ingredient.

The prevention of secondary complications is not limited to proper treatment for poisoning. Lack of treatment or inadequate treatment may introduce further stresses. For example, in Mexico, as has been pointed out, there are a significant number of deaths each year caused by tetanus in the age group 5-14 years.

REHABILITATION SERVICES: Applied early, rehabilitation services contribute to reduction in the degree of disability following severe injury. Indeed, the caseload of rehabilitation centers in the Americas is comprised largely of accident

victims. As more of these facilities are developed and the time lag between injury and rehabilitation services is decreased, a marked improvement can be expected. Although the expense of rehabilitation is usually well justified, the prevention of serious injury is even more economical.

Summary

Extension of current trends suggests that accidents will, within the next two decades, be the leading cause of death in children 1 to 15 years of age in many nations of the Americas.

Rehabilitation centers in the Americas report that caseloads are comprised largely of accident victims.

Each specific hazard must be identified and prevented on an individual basis, but traditional public health procedures, such as epidemiology, provide tested methods.

Although diseases such as gastritis and enteritis are the first cause of death for half the countries of the Americas in the 1 to 4 age group, accidents are the leading cause in two-thirds of these countries in the 5 to 14 age group. Nonfatal accidents are found to cause great economic loss because of resultant disabilities and longer and more expensive hospitalizations. Motor vehicle accidents, drowning, burns, poisoning, falls, and bites of insects and snakes are leading causes of accidental death. With significant exceptions, boys have more accidents than girls. More than one-half the accidental poisoning cases occur under 2 years of age, the toxins varying from country to country.

Mortality and morbidity data gathered from surveys are essential bases for initiating accident prevention activities by health departments. U.S. National Health Survey data indicate 45 percent of all accidental injuries occur in the home.

Accident survey data help to define epidemiological study areas and aid evaluation of programs. Accident causation, the subject of increasing study, is extremely complicated and awaits the application of a multidiscipline approach. The host-agent-environment triad of the epidemiological method is relevant. Accurate record systems are essential to accident studies. Analysis of accurate records has made

possible specific successful prevention activities in the United States and can serve other nations of the Americas.

Both longitudinal and retrospective studies of childhood accidental deaths and injuries contribute to prevention.

Primary and secondary prevention benefit equally by educational activities. Education in accident prevention is also a major duty of a public health agency. Physicians can perform valuable educational work in this field.

Health departments can establish leadership in accident prevention and coordinate the work of other community groups.

Research is needed in epidemiology, educational techniques, and emergency treatment and first aid. Emergency treatment services can be greatly strengthened as a secondary prevention technique.

Epidemiological Notes

Meningococcal Infections

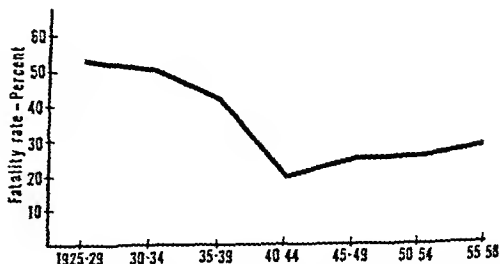

A progressive decline in mortality from certain bacterial infections followed the introduction of sulfonamides in 1937 and of antibiotics in the next decade. The fatality rates for meningococcal infections declined from a level of about 40 percent just prior to the use of sulfonamides to about 20 percent during the next few years. However, in the past 15 years the fatality rate has remained at a slightly higher but relatively constant level of about 25 percent, as shown in the chart.

The two principal classes of meningococcal infections are meningitis and septicemia. The number of deaths for each of these types has fluctuated with increases and decreases in reported incidence of cases. About 1950 approximately two-thirds of all deaths from meningococcal infections were attributed to meningitis, but during the past few years there has been about the same number ascribed to meningococcemia as to meningococcal menin-

gitis. Since no morbidity data by type of infection are available, it cannot be determined whether the septicemic form is becoming relatively more frequent.

The number of deaths from meningococcal infection currently reported annually is about 800, which is far in excess of those from diphtheria, measles, streptococcal sore throat and scarlet fever, typhoid fever, or whooping cough. Since 1955 meningococcal infection has outranked poliomyelitis as a cause of death.

Case fatality rates for meningococcal infections, United States, 1925-58.

The fact that this acute infection causes 800 deaths a year and 1 fatality for every 4 cases reported suggests the need for the development of more effective methods for its control.—DR. CARL C. DAUER, *medical adviser, National Office of Vital Statistics, Public Health Service.*

Poliomyelitis in the United States, 1957

LAURI D. THRUPP, M.D., HELEN E. FORESTER, B.A.,
and JACOB A. BRODY, M.D.

POLIOMYELITIS reported in the United States during 1957 reached the lowest level since 1942. A total of 5,485 cases were reported to the National Office of Vital Statistics, Public Health Service, a rate of 3.2 per 100,000 population. Of these cases, 2,499 were reported as paralytic, and 2,826 nonparalytic. The paralytic status was unspecified for the remaining 160 cases.

Table 1 presents total national poliomyelitis incidence rates from 1935 through 1957 as reported to NOVS. Although wide annual variations occurred, the incidence of poliomyelitis remained high from 1948 through 1955. During 1956, half as many cases occurred as during the previous year, while in 1957, reported cases were only one-fifth of the 1955 figures.

Seasonal Distribution

Variability in seasonal distribution patterns as well as in annual poliomyelitis incidence in recent years is further apparent from figure 1, which presents the seasonal curve of weekly reports to NOVS for the years 1942, 1947, and 1952 through 1957.

For paralytic poliomyelitis alone, as shown in figure 2, the seasonal rise in 1957 was gradual, and peak incidence was not reached until

the end of September (39th week), much later than the late August peaks reached in 1955 and 1956. Data specifying paralytic status, prior to 1955, are not available on a nationwide scale.

During 1957 the seasonal distribution curve for paralytic poliomyelitis differed considerably from nonparalytic poliomyelitis. Cases reported in the *poliomyelitis surveillance program* during 1957 by week of onset are presented in figure 3. Whereas nonparalytic disease reached a sharp, seasonal peak in early August, paralytic poliomyelitis rose gradually to a minor peak in early August and subsequently remained at a plateau, not reaching maximum weekly incidence until almost 2 months later. The proportion of paralytic cases among reported poliomyelitis cases was notably lower in all regions of the country during July and August as compared with the remainder of the year.

Morbidity Reporting

In recent years increasingly widespread application of virus diagnostic tissue-culture techniques has permitted study of numerous outbreaks of nonparalytic aseptic meningitis. It is now well documented that many agents of the ECHO and Coxsackie groups are capable of producing an illness clinically indistinguishable from aseptic meningitis caused by the poliovirus. On rare occasions these agents have also been associated with paralytic disease.

During 1957, large outbreaks of illness with aseptic meningitis syndrome due to nonpoliomyelitis enteroviruses were recorded in many States, including Wisconsin, Minnesota, Michi-

Dr. Thrupp, formerly chief of the Poliomyelitis Surveillance Unit, Communicable Disease Center, Public Health Service, Atlanta, Ga., is now with the Fourth Medical Service, Boston City Hospital. Miss Forester is a statistician and Dr. Brody, epidemic intelligence service officer, with the Poliomyelitis Surveillance Unit.

Data Collection

Basic functions of the National Poliomyelitis Surveillance Program are the continual collection of data on the safety and efficacy of poliomyelitis vaccine and the study of the epidemiological trends of poliomyelitis in the United States. Established in April 1955 at the Communicable Disease Center of the Public Health Service, the program is based on participation by local and State health departments, the National Office of Vital Statistics, diagnostic and research laboratories, the National Foundation for Infantile Paralysis, and others with responsibility and interest in the field of poliomyelitis and poliomyelitis-like diseases. Mimeographed Poliomyelitis Surveillance Reports are issued regularly, reviewing data reported in the program. In addition to these periodic reports, reviews of information recorded in 1955 and 1956 have been presented (1-4).

During 1957, 47 States, the District of Columbia, and three Territories participated with the Poliomyelitis Surveillance Unit in studying data, including age, race, sex, date of onset of symptoms, paralytic status, and vaccination status of reported poliomyelitis cases. The present report reviews poliomyelitis incidence during 1957 and summarizes the epidemiological patterns in that year in comparison with 1955 and 1956.

gan, Ohio, North Carolina, Virginia, and Tennessee. These included communitywide epidemics of febrile illnesses often with aseptic meningitis symptoms or skin rash, or both, associated with ECHO-9 virus.

With reported poliomyelitis at a low level, individual case diagnosis has become more important. During the year, a relatively low percentage of cases were paralytic. This percentage was lowest in July and August, the period during which the aseptic meningitis epidemics were occurring. A proportion of the cases reported as nonparalytic poliomyelitis during this time are felt to have been caused by the ECHO and Coxsackie viruses. Included in this group are endemic aseptic menin-

gitis cases, as well as early cases from aseptic meningitis outbreaks later demonstrated epidemiologically and virologically to be due to other than polioviruses.

Routine practices in the morbidity reporting of such cases vary. While a number of non-poliomyelitis aseptic meningitis cases were included in routine morbidity reports as nonparalytic poliomyelitis, data recorded in the epidemiological reports to the Poliomyelitis Surveillance Unit were refined in some States by subtraction of cases from known aseptic meningitis outbreaks initially reported as nonparalytic poliomyelitis.

Distribution

Geographic

In contrast with recent years, no large outbreaks of paralytic poliomyelitis occurred during 1957 in the United States. Table 2 presents poliomyelitis cases reported in the poliomyelitis surveillance program by State and region during 1956 and 1957 and estimated attack rates by paralytic status. The generally low incidence of paralytic disease in all regions is apparent. Highest attack rates for 1957 were reported in the southeastern, south central, and southwestern regions, where paralytic rates were 1.8, 2.9, and 2.0 per 100,000,

respectively. Only Texas and the District of Columbia reported more than 3 paralytic cases per 100,000, whereas in 1956 this rate was exceeded in 27 States.

Age

During the past 5 years there has been a progressive rise in the proportion of paralytic cases among preschool children. As shown in

Figure 1. Poliomyelitis incidence in the United States, 1942, 1947, 1952-57.¹

¹ Provisional data from the National Office of Vital Statistics, Public Health Service.

table 3, 44 percent of paralytic cases reported in the 1957 poliomyelitis surveillance program were in children under 5 years of age, compared with 42 percent in 1956, 32 percent in 1955, and 29 percent in 1952. This concentration of paralytic poliomyelitis in the preschool age group was observed throughout the Nation, although the tendency was more marked in southern regions.

In figure 4, age-specific attack rates for paralytic poliomyelitis in the United States during 1955, 1956, and 1957 are plotted on a logarithmic scale. During 1957, as in 1956, the highest age-specific rates occurred at 1 year of age, with a rapid decline thereafter to relatively stable rates beyond age 10. This pattern is in contrast with the experience during the previous 20 years (5), when attack rates in this country generally tended to remain high throughout the first decade.

The remarkable trough in paralytic poliomyelitis attack rates among children 7 and 8 years in 1955 has persisted in this cohort through 1956 (then 8 and 9 years of age) and

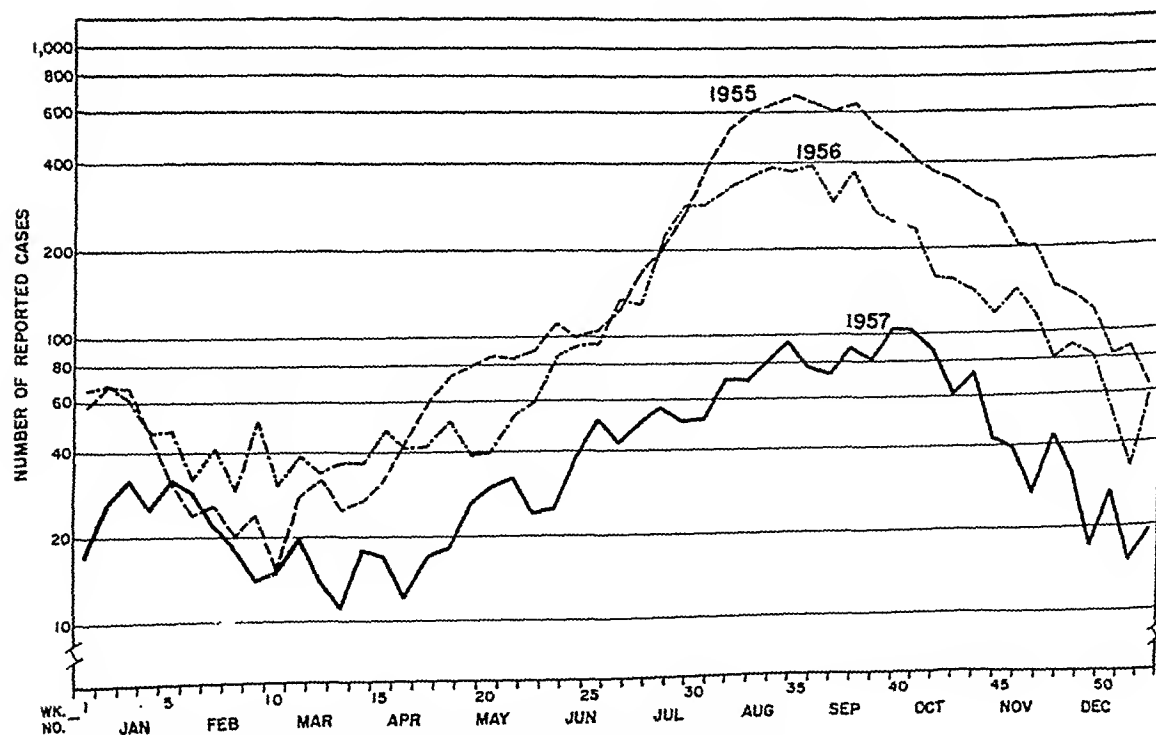

1957 when the lowest rates were among the 9- and 10-year-olds (fig. 4).

For nonparalytic poliomyelitis, in contrast with paralytic, the age distribution during 1957 was not appreciably changed from the pattern of 1952, 1955, and 1956 (table 3). The largest proportion of cases appeared in the 5- to 9-year age group, and the estimated age-specific attack rates for nonparalytic disease peaked approximately at ages 3 through 7.

Sex

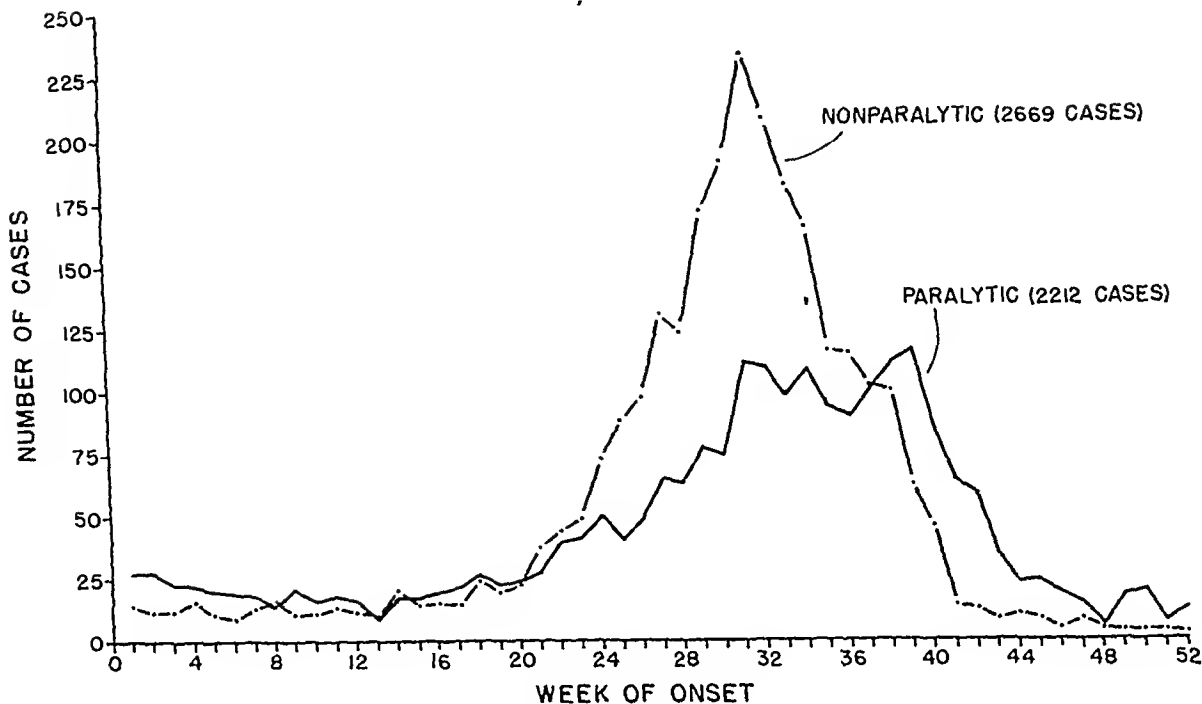

During 1957, just as in 1956 and in previous years, total poliomyelitis incidence in males exceeded that in females. In recent years, however, incidence in young adult females has tended to exceed that in males (3, 5). This pattern was seen in 1956 (4), when more cases occurred in females than in males at age 12 and ages 20 to 24. During 1957 the cases in females outnumbered the cases in males throughout the 20- to 40-year age group (table 4), but when corrections are made for the fact that the female population exceeds the male population

Figure 2. Paralytic poliomyelitis incidence in the United States, 1955-57.¹

Figure 3. Seasonal incidence of poliomyelitis in the United States, 1957.¹

¹ Cases reported to the Poliomyelitis Surveillance Unit, Communicable Disease Center, Public Health Service.

in this age group, these differences are not so prominent.

Racial

Current age-specific attack rates cannot be derived by race since nationwide population estimates by race and age are not available beyond the 1950 census and since reporting of poliomyelitis by race is not a uniform practice.

Nevertheless, data from southern States and from several urban areas suggest that paralytic poliomyelitis attack rates in Negro populations are increasing both absolutely and relative to the rates in whites. Estimation of paralytic poliomyelitis attack rates by race in southern States in 1955 revealed the rate among whites to be 1.8 times that among nonwhites, while in 1957 the rate among whites was only 0.75 times that for nonwhites (6).

In the 1956 Chicago epidemic attack rates for paralytic poliomyelitis among Negroes were almost eight times those in whites (7,8). During 1957, the only large city with any concentration of poliomyelitis was Washington, D.C., where the paralytic attack rate in nonwhites was four

times as high as in whites. In 1956 and 1957, study of 14 additional urban areas reveals that 6 of these 14 experienced a similar increase in paralytic rates among nonwhites, in contrast with patterns of previous years. These areas were Philadelphia, Richmond, Norfolk, New York, Baltimore, and Atlanta.

Vaccination History

Evidence suggesting poliomyelitis vaccine effectiveness in the prevention of paralytic disease continued to accumulate during 1957. Table 5 presents by age group the proportion vaccinated of paralytic and nonparalytic cases reported during 1957 in the poliomyelitis surveillance program from 47 States and the District of Columbia. Since much of the nonparalytic illness was caused by nonpolioviruses against which the vaccine is ineffectual, it was expected that the proportion vaccinated among nonparalytics would be higher than among paralytics. This higher incidence among nonparalytics was observed in all age groups. An

overall total of 54 percent of nonparalytic cases had received some vaccine as compared with 30 percent of paralytic cases.

The ability of the vaccine to modify the clinical characteristics of the disease is indicated in the correlation which exists between number of doses received and absence of paralysis. Whereas 56 percent of all nonvaccinated poliomyelitis cases were paralytic, only 25 percent of all triply vaccinated cases were reported paralytic.

Data obtained in August and November of 1957 for the Poliomyelitis Vaccine Activity Unit by NOVS through a supplement to the Census Bureau's Current Population Survey permitted an estimate of the vaccination status

of the United States population by age group. This analysis was under the direction of Dr. Monroe Sirken, chief, Actuarial Analysis Section, National Office of Vital Statistics. Using as numerators the vaccination history of cases of paralytic poliomyelitis reported by age groups in the poliomyelitis surveillance program and as denominators the above United States population estimates by age group and vaccination status, rough calculations of paralytic poliomyelitis attack rates were derived in vaccinated and unvaccinated populations. The estimated paralytic poliomyelitis rates were lower in the triply vaccinated than in the unvaccinated population (table 6). The percentage reduction ranged from 90 percent in the 0-4 year age group to 54 percent in the 20-29 year age group.

Such estimates represent uncontrolled comparisons of ratios rather than measured attack rates in controlled populations, and as such are subject to many potential errors. Such factors as variations in the vaccine status in different areas, ages, and population groups, and variations in the actual exposure to virus in individual groups should be taken into account in analyzing effectiveness of vaccine. Various studies are in progress at the present time to evaluate vaccine effectiveness in more controlled population subgroups.

Triply Vaccinated Cases

Cases occurring in triply vaccinated persons during 1957 included 207 paralytic, 588 nonparalytic, and 1 unspecified case. Of these, lab-

oratory data were reported on 85 paralytic cases and 171 nonparalytic cases (table 7). Studies were negative in the large majority of these cases; only 19 percent of the paralytic and 15 percent of the nonparalytic cases studied were confirmed as exhibiting current or recent infection with poliovirus, while other viruses were isolated in 10 percent of the paralytic cases and in 20 percent of nonparalytic cases.

Data regarding the extent of paralytic involvement remaining after convalescence were

submitted by physicians in 135 cases (table 8). Residual paralysis was roughly estimated to be severe in 42 cases, moderate in 39, and mild in 54 cases. Of the severe cases poliovirus infection was confirmed in 7 and laboratory studies were negative in 15.

During 1957 three deaths from poliomyelitis were reported in triply vaccinated persons. Pathological findings were characteristic of acute poliomyelitis in one case from which type 3 poliovirus was isolated. In a second case, pathological findings were suggestive but laboratory studies were negative. The remaining fatal case was not confirmed; postmortem examination was not performed, and no material for virus isolation was available.

Vaccine Distribution

During the period April 1955 through December 1957, a cumulative total of 186.2 million cc. of net bottled poliomyelitis vaccine was distributed for domestic use. This total includes 27.7 million cc. shipped during the period April–December 1955, 70 million in 1956, and 88.2 million in 1957. In addition, 19.2 million cc. were exported during the period August 1956 to December 1957. During 1957, shipments lagged considerably behind releases, and a balance of 33.1 million cc. was cleared by the National Institutes of Health but not shipped by the end of the year. Distribution of vaccine by calendar quarters is presented in figure 5.

Vaccine Safety

Reporting of cases occurring within 30 days of a poliomyelitis vaccine inoculation was less thorough during 1957 than in 1955 and 1956. Analysis of 36 cases in 1957 with complete data revealed no tendency for the onset of illness to group in the 4- to 11-day period following inoculation. Onset of paralysis occurred in the inoculated limb in six cases and in the opposite uninoculated limb in four cases during 1957. No specific vaccine lot was known to be associated with more than three paralytic cases. The 1955 Cutter cases, in contrast, were associated with a small number of specific lots, and paralysis usually began in the inoculated limb 4 to 11 days following vaccination (1).

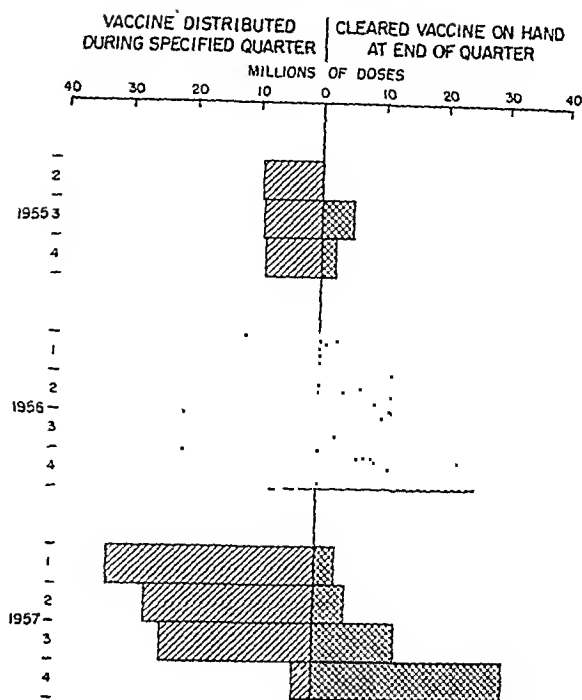

Discussion and Summary

Reported incidence of poliomyelitis in the United States during 1957 reached the lowest level since 1942. There were no major poliomyelitis outbreaks, and attack rates, particularly of paralytic disease, were low in all regions of the country.

Concurrently, during 1957 almost 90 million cc. of poliomyelitis vaccine were shipped in this country, bringing to over 180 million cc. the total vaccine distributed for domestic use since April 1955. More than half of our population has now received at least one dose of vaccine.

The extremely low incidence for paralytic poliomyelitis of 1.5 cases per 100,000 during 1957 is impressive in view of the extensive use of vaccine. However, marked annual variations have characterized poliomyelitis incidence

Figure 5. Poliomyelitis vaccine distribution, 1955–57.¹

¹ Data from Poliomyelitis Vaccine Activity Unit, Bureau of State Services, Public Health Service.

in this country in recent years. Furthermore, response to commercial poliomyelitis vaccine has been variable (9), and vaccinated subjects appear to be readily susceptible to gastrointestinal infection upon natural exposure to poliovirus (10–12). Therefore, it cannot be concluded that the widespread use of vaccine was alone responsible for the low total incidence of the disease during 1957. Final evaluation of the effect of inactivated poliomyelitis vaccine on poliovirus ecology and on total poliomyelitis incidence will require continued study over the next several years.

Changes in epidemiological patterns may nevertheless reflect the size and character of the vaccinated population since the Nation is not uniformly vaccinated. It has, therefore, become of increasing importance to continue detailed study of epidemiological trends of poliomyelitis in this country.

The striking change in age distribution pattern of paralytic disease observed during 1956 continued through 1957, with preschool children accounting for the largest proportion of cases

and with peak age-specific attack rates encountered in 1-year-old infants. Since the preschool ages were less thoroughly vaccinated than older children, it is probable that this change in the relative age distribution is at least in part a result of the vaccination programs. The trough in age-specific attack rates for paralytic poliomyelitis noted in 1955 among 7- and 8-year-olds and again in 1956 among 8- to 9-year-olds has persisted this year among the same cohort, now 9 and 10 years of age. Since this group in particular was thoroughly vaccinated in the school programs of 1955, the persistence of lowest paralytic attack rates in this population for 3 years suggests both effectiveness of the vaccine and duration of the induced immunity over the 3-year period.

Relatively and absolutely increased incidence of paralytic poliomyelitis was encountered during 1956 and 1957 among nonwhite racial groups in the south and in several metropolitan areas throughout the country.

Paralytic poliomyelitis cases tended to occur among unvaccinated individuals during 1957. Examination of vaccination history for paralytic cases in comparison with the estimated vaccination status of the United States population has permitted gross but reasonable estimations of paralytic attack rates in vaccinated and unvaccinated populations. The rate of paralytic disease in the triply vaccinated group was apparently reduced compared with that in unvaccinated populations. Further, a progressively lower incidence was recorded for those who had received 1, 2, or 3 doses of vaccine. These variations in calculations of effectiveness of three doses of vaccine reflect the unequal exposures of populations to virus and differing vaccination status of specific groups. The estimates are useful in determining the range rather than the specific degree of effectiveness.

Poliomyelitis vaccine shipments declined during the latter part of 1957. It is evident that increasingly active immunization programs will be required in order to achieve completion of the requisite three-dose schedule in large segments of the population as yet incompletely

vaccinated. Particular effort will be necessary in groups at relatively increasing risk, including the preschool ages and nonwhite populations.

Youth is the period of building up the habits, hopes, and faiths. Not an hour but is trembling with destinies.—JOHN RUSKIN.

Federal Interest in Juvenile Delinquency

AIMS C. McGUINNESS, M.D.

MANY American children grow up in a rough world. They come from homes broken by desertion, divorce, or separation, or are children of unwed mothers. These, generally, are the youngsters, deprived of a father's support, who are dependent upon the Federal-State aid to dependent children programs for the bare necessities of life. Throughout the Nation there are more than 2 million of these children.

There are many pressures. Thousands of children under 12 years of age, whose mothers work full time away from home, have no daytime afterschool supervision. There is no telling how many children live in undesirable neighborhoods with substandard housing. Every year millions of children change schools, moving from State to State, from town to town, or into different neighborhoods. Many children, of course, grow up in combinations of these unfortunate situations, these pressures.

And from their numbers come many of the disturbed children, the youngsters in conflict with the law, members of what has been called "the shakedown generation."

Police currently handle more than 1.7 million cases of juvenile misbehavior a year. About a quarter of these, or 428,000, are referred to the juvenile courts by police; an additional 175,000

delinquency cases are referred to juvenile courts by parents, teachers, or social agencies, making a total of more than 600,000 delinquency court cases every year.

Their number grows. The delinquency cases handled by the juvenile courts increased by 137 percent between 1948 and 1957, whereas the child population from 10 to 17 years of age increased only 28 percent.

By 1965 there will be an estimated 30 million children in the United States in this high-risk, vulnerable age group, a third more than in 1957. If the incidence of juvenile delinquency continues to increase at the same rate as it has since 1948, then by 1965 the juvenile courts will be handling delinquent children at an annual rate of about a million cases. And by then, police will be handling a much greater number, many of which will never reach the courts.

There isn't any simple solution, as we all know. But we know, too, that juvenile delinquency has reached perilous proportions. Two things urgently need doing: first, we must arouse ourselves and our communities to get on with the job of doing those things that could and should be done now, and second, we must pursue with vigor the search for better understanding of the basic conditions which lead to this fearsome complex of social behavior.

Cooperative Efforts Needed

Successful efforts to combat juvenile delinquency require cooperation. It is a job for a number of people: the parents and relatives,

Dr. McGuinness is special assistant to the Secretary for Health and Medical Affairs, Department of Health, Education, and Welfare. He presented the full text of this paper before the Michigan Branch of the American Academy of Pediatrics in Detroit, March 10, 1959.

Standard Family Court Act

Family courts would take the place of separate juvenile and domestic relations courts in model State legislation developed by the National Probation and Parole Association in cooperation with the Children's Bureau, Department of Health, Education, and Welfare, and the National Council of Juvenile Court Judges.

The model legislation, entitled the "Standard Family Court Act," was published in April 1959, in the *Journal of the National Probation and Parole Association*, as the culmination of a 4-year project.

The need for a unified court approach to family problems has been indicated by various students of judicial procedure since early in this century. The new standard act represents a radical departure from previous model legislation by bringing together, under the jurisdiction of a single court, the major legal issues and problems of a personal nature which arise within families.

The family court, as proposed, would be set up on a statewide basis and would include a corps of specialized services within each court to treat such problems as delinquency and neglect, as well as provide special services in cases involving divorce, legal separation, support, adoptions, and certain criminal actions involving adults who commit offenses against children or other members within a family.

The new proposal, for the use and implementation by State legislatures, spells out the duties and responsibilities of the court as well as its relationship to other agencies. It sets up safeguards around the rights of parents and children in its provisions for legal counsel and in certain limitations it places on the court's procedures and disposition powers.

Specifically prohibited by the act would be transfer of a delinquent child to an institution for adult criminals; placement of a neglected child in an institution for delinquents; and subjecting a child to criminal court penalties and juvenile court control for the same offense.

The organizational pattern of the family court act would permit the establishment on a national basis of an accurate count of the number of children and families in trouble. Statewide reporting exists now in several States but not on a unified basis.

the doctor, the psychologist, the teacher, the social worker, the minister, the lawyer, and the police. And it is a job for citizens groups, voluntary organizations, and government at all levels, local, State, and Federal. The main work, of course, must be done in the communities, for troubled youngsters must be reached in person, in their homes, their churches, their schools, or on streets and back alleys, if that's where they are.

At the same time, juvenile delinquency is a matter of State and Federal concern. Because it is a highly complicated problem, many diversified approaches are required in its solution. In one way or another, it is of concern to virtually every unit of the Department of Health, Education, and Welfare.

The Children's Bureau, with responsibility for helping improve the conditions under which children are born and grow up, has a particular concern for those youngsters in conflict with society. In 1955 it established the Division of Juvenile Delinquency Services, whose staff members on request give professional consultation to juvenile courts, probation officers, police, youth commissions and councils, and citizens' organizations in cities and counties all over the country.

An important function of this unit is the development, in consultation with State and local authorities, of standards and guides for the use of professional personnel and agencies concerned with juvenile delinquency. A much-needed standard for the use of juvenile courts has been completed. In cooperation with the National Probation and Parole Association and the National Council of Juvenile Court Judges, the Children's Bureau is now working on a revision of the family and juvenile court acts.

As in the past, the Children's Bureau is the focal point in the Federal Government for initial planning of the White House Conference on Children and Youth. This historic conference, which has been called by the President of the United States in every decade in this century, will concern itself in 1960 with lasting values in the changing world. The problems of juvenile delinquency undoubtedly will have an important place in the program.

Between now and 1960, communities, States, and the Federal Government will be examining

how our changing world is affecting children. Specifically, study groups will explore such things as family, religion, and the arts. They also will look at community organizations and services as they impinge on the life of the child. In addition, they will inquire into the manner in which the behavior of adults, in their interactions with children and youth, deter or foster individual fulfillment and constructive services to humanity.

I am sure the many studies leading up to the conference will give us valuable new insights into the ultimate solution of juvenile delinquency prevention.

Prevention Main Objective

Prevention is the central objective of many other Federal activities that bear directly or indirectly on the question of juvenile delinquency. In 1956, the President called the first Conference on Fitness of American Youth, and subsequently created the President's Council on Youth Fitness and a Citizens' Advisory Committee to that council. For the past 2 years it has been my privilege to represent the Department of Health, Education, and Welfare on the Interagency Advisory Group to the Council.

The President has thus brought together many creative minds and new energies for a single purpose: to stimulate and encourage the building of men and women of physical, moral, and spiritual strength.

In the words of Homer C. Wadsworth, of Kansas City, chairman of the Citizens Advisory Committee, "The Council should serve three main purposes: (a) to continue to alert the American people to the need for special emphasis on the fitness of American youth; (b) to act as a clearinghouse for information on activities proven to be especially effective in this regard; and (c) to encourage a more effective coordination of public and private services in our communities designed to promote youth fitness."

These and other related activities are bound to bring enormous benefit to our children and young people. A really heartening advance was made for children when Congress last fall amended the Social Security Act to authorize the Children's Bureau to provide welfare serv-

ices for children in urban areas on the same basis as for rural children, services that will help to keep children in their homes and strengthen family life; that protect babies who are going to be adopted; that provide good foster homes when necessary; that help children in danger of becoming delinquent. This is the first time that Federal funds have been authorized to augment and strengthen local and State public and voluntary efforts.

In 1956, Congress amended the Social Security Act to give emphasis to social services in public assistance programs that lead, importantly, to the strengthening of family life and that help stimulate city and community efforts to help families and individuals get back on their feet and to tap all sources of help for families in trouble.

By incorporating in the legislation the word "services," Congress gave a powerful incentive to the States to move in the direction of prevention of human disasters that so frequently happen when a family undergoes a social breakdown. To move in the direction of helping people off assistance rather than helping people on assistance is the goal toward which all these programs must strive.

The Family Approach

The family approach to social problems is of real significance in the treatment of juvenile delinquency. Disturbed youngsters often come from disturbed families. And when we, as a Nation, are able to do a better job of reaching these multiproblem families, we will have come a long way in helping prevent juvenile delinquency and other social ills. Among the individual members of these families will be found not only juvenile delinquency but combinations of all the other problems that confront our society today: mental illness, physical disability, alcoholism, unmarried parenthood, broken homes, prostitution, drug addiction, and many others. These are the marginal families, dependent or potentially dependent. Their children are in "clear and present danger."

It should be emphasized that multiproblem families are not confined to low-income groups. There are probably as many multiproblem

families among the self-supporting as there are among families on public assistance. Problems of a family often first show up on hospital records, when an illegitimate baby is born or a mentally ill person is identified, or on police records, when a youngster comes in conflict with the law, or even on school records, when a child is consistently truant or an academic failure.

No one, of course, knows just how many of these families there are. But from a recent analysis of 25 cities based on records of official agencies, we get a rough idea of the number of families that have undergone a social breakdown. In half the cities the rate was 67 families per 1,000. Eastern and northern cities showed a rate between 29.4 and 78.3 families per 1,000. Southern cities had a uniformly higher rate.

These families are not all in hiding. Many are known to social agencies, teachers and the clergy, and members of our profession, and they are frequently known to the police. It makes sense to bend every effort to reach a family before it becomes dependent, or failing that, to help a swamped family get back on its own feet, emotionally and financially.

And that again is what the Department is trying to foster through its new emphasis on social work in the public assistance programs. This approach is gaining momentum all the time. But the full potential of public assistance programs will be approached only when all the resources of the community, public and private, that could possibly be of help to families in trouble are brought together in an organized way to bear upon immediate problems.

Program Interrelationship

In this and other programs of the Department, we seek to destroy the seeds of social evils before they have had a chance to germinate. The programs are interwoven, interrelated.

The Office of Education, alerted to the role that schools can play in identifying and helping delinquents or potential delinquents, has contracted with a number of universities and colleges for research studies on various aspects of juvenile delinquency in its relation to education.

One of the provisions of the new National

Defense Education Act should have an extremely beneficial effect in the prevention of juvenile delinquency. This is the title that sets up a nationwide system of testing, backed up by counseling and guidance programs. It seems to me that when special talents in boys and girls are identified when they are young, and when they are encouraged to pursue these talents and make the most of themselves, there will be a good deal less risk that they will become members of street gangs or get in trouble with the law. School counselors in many cases should be able to identify potentially delinquent children and bring community resources to bear on their problems in time to prevent real trouble.

The Public Health Service is intensifying its efforts in areas of mental health, with a number of significant programs relating to juvenile delinquency. Important fundamental work was done last year by scientists of the National Institute of Mental Health toward clarifying some of the basic mechanisms of psychological development and human behavior.

It is very encouraging to note the widespread expansion of community mental health programs. A high share of the cost of these programs is being provided by State and local resources. An alltime high of \$54 million was expended, from all sources, for these purposes during the past year, but only 7.4 percent of this represents Federal funds.

Delinquency In Perspective

I think, in any discussion of juvenile delinquency, we should put statistics in perspective. Not all of our children are growing up to be troublemakers. Most parents do a good job. Churches of all denominations have a large membership among children and young people. And our schools and numerous youth-serving organizations are doing a commendable job in promoting good citizenship.

But for those children who are delinquent, or likely to become so, we have an obligation to do what we can, when and where we can, and to start doing it now!

From its earliest days, our Nation has been a symbol of freedom to the rest of the world, freedom to stretch our minds in the way they incline, freedom of opportunity. Of the

world's 2½ billion people, somehow our Nation of 175 million has managed to accumulate almost half of the world's wealth.

We have the resources and much of the know-how to end hunger and scarcity and poverty and disease, and to slash out at social evils that have beset mankind through the ages. We have the resources to encourage more intellectual attainment among more young people. In our

own generation we could bring untold benefit not only to ourselves and our children, but to future generations of all people of the world.

Surely, amidst our plenty, we can realize the sheer practicality and find the resources of time, energy, money, and creative thinking to help these thousands of boys and girls in our society whom society, in some way, has failed and whom we have tagged "delinquent."

Protection of Dairy Products

As a result of developments such as the mass production of penicillin and of chlorinated hydrocarbon pesticides and the widespread use of these chemicals on the farm, interstate concern with milk has multiplied. In 1949, the Department of Agriculture joined the Food and Drug Administration in advising farmers that sprays containing DDT should not be used on milk cows or in dairy barns. These uses have largely been discontinued.

We have found that when a cow eats feed that contains DDT, she excretes the pesticide in her milk. Most of the other chlorinated hydrocarbons also leave poisonous residues in milk when used on the cow or her feed.

When penicillin is infused into the cow's udder to treat mastitis, it comes out in the milk for a considerable period of time. Some farmers are using chlorinated hydrocarbons and penicillin improperly and residues of these chemicals are showing up in milk. Although the residues are very small, they cannot be tolerated.

Our limited surveys of milk conducted in 1954 and 1955 disclosed that 3 percent of the 1954 samples and more than 11 percent of the 1955 samples contained minute quantities of penicillin. A larger survey in 1956 covering the entire country showed similar penicillin residues in about 6 percent of the samples.

In our nationwide survey of market milk for pesticide residues in 1955, quantitative chemical tests on 169 samples believed to have

highest insecticide residues (based on earlier bioassay) showed 33 samples with residues ranging from 0.05 to 1.5 ppm of DDT, or its equivalent.

Remedial steps we have taken since then include the requirement that penicillin-containing drugs for treating mastitis by infusion into the cow's udder must bear a warning on the label itself that milk from treated cows should not be used as food for 72 hours after the treatment; formerly, this warning might appear only on the circular shipped with the drug. The penicillin content of mastitis treatments is now limited to 100,000 units per dose; formerly much larger amounts were being used.

A recent nationwide survey gave the following preliminary findings:

- Around 0.1 ppm of chlorinated hydrocarbons by chemical tests in about 4 percent of almost 800 market milk samples tested. The more sensitive bioassay shows a higher percentage of samples with residues.

- Penicillin residues in 3½ percent of more than 1,100 samples tested. When the positive samples were averaged, the penicillin content was approximately 0.1 unit per milliliter of milk. (These percentage figures are not strictly comparable with those obtained earlier because of some variation in sampling procedures.)

It is clear that there has been significant improvement in the milk supply. This reflects sincere, extensive efforts.

—Excerpt from a speech delivered by George P. Larrick, Commissioner of Food and Drugs, at the Dairy Products Improvement Institute in New York City, February 19, 1959.

Although automobile exhaust contains dozens of compounds, only a limited number of these are a potential public health hazard.

Health Hazards of Automobile Exhaust

JOHN R. GOLDSMITH, M.D., M.P.H., and LEWIS H. ROGERS, Ph.D.

THE GASES, vapors, and particles in automobile exhaust are considered by many to be the major contributing factors of Los Angeles' air pollution, which is so strikingly characterized by irritation of the eyes (1,2). Other west coast cities, including San Diego and San Francisco, appear to have a similar problem in less severe form. We have learned that when the nitrogen oxides and partly burned fuel of automobile exhaust are irradiated the characteristic photochemical type of smog is produced (3). Concern regarding this form of air pollution derives both from the widespread symptoms and from the possibility of immediate or long-term effects on health (4). If attention is focused on hydrocarbons and nitrogen oxides, in an effort to abate eye irritation, other adverse effects of automobile exhaust may unfortunately be ignored. This review attempts to place these other effects in perspective.

When only a few automobiles are driven on country roads, there is no public health problem, but when thousands of cars are operated in a small area with a limited supply of fresh air, automobile exhaust may constitute a potential hazard to the health of the community. This will be true even in the absence of irritated eyes and reduced visibility, so characteristic of photochemical smog.

Dr. Goldsmith is head of studies of health effects of air pollution, California State Department of Public Health, Berkeley, and Dr. Rogers is associate director, Vitro Laboratories, West Orange, N.J., and formerly senior chemist, Air Pollution Foundation, San Marino, Calif.

The solution of two imperative questions lies in the future: How much exhaust can be tolerated in how much air? When does this potential hazard become an actual one? For the present, we shall concern ourselves with what is known about the constituents of automobile exhaust and with an approach to answering these questions.

Composition of Automobile Exhaust

We are confining our attention to air pollution from spark-fired internal combustion engines and excluding that from diesel engines. In most urban areas, the latter, although sometimes a local nuisance, is of lesser importance to the community. In Los Angeles, for example, the air pollution from diesel engine exhaust is about 20 tons of organic emissions per day, whereas auto exhaust contributes about 1,200 tons of organic emissions per day (5).

When a petroleum fuel is completely burned, the products are carbon dioxide and water, together with nitrogen and unused oxygen from the air. However, in a spark-fired internal combustion engine some of the nitrogen is also oxidized producing the several oxides of nitrogen. In automobiles the ratio of air to fuel is seldom maintained at the theoretical value of 15:1 required for complete combustion. More frequently, this ratio amounts to about 12:1 at idling and 13.5:1 at cruising.

Under these conditions, other products appear in the exhaust, including carbon monoxide, hydrogen, aldehydes, and unburned hydrocarbons. In addition, oxides of sulfur occur in

exhaust depending on the amount of sulfur in the fuel, and lead compounds are present in a form determined by the additives used in the fuel. Because of tremendous differences in operating conditions, condition of cars, and other factors, it is difficult to give representative analyses. Some characteristic ranges of exhaust gas composition are presented in table 1. Of the constituents listed in table 1, we shall consider only hydrocarbons, oxides of nitrogen, lead compounds, and carbon monoxide.

Effects of Time and Weather

Since the composition of exhaust gas is so variable and is quickly diluted several hundred-fold when it is released to the atmosphere, knowing the actual concentrations of exhausted gases in the atmosphere is important. These concentrations are affected by windspeed, presence and intensity of a temperature inversion; vehicle operating conditions, number of automobiles operating per square mile, and further reactions of the atmospheric constituents. To illustrate how high the concentrations may become, table 2 shows values of hydrocarbons and carbon monoxide at five busy intersections in Los Angeles during peak traffic and adverse weather conditions.

About 5,000 vehicles per hour passed the intersections at which the samples were taken except at Hollywood and Harbor Freeways, where about 11,000 per hour passed.

Community and Industrial Exposure Hazards

The substances listed in table 1 have been subject to conventional toxicological studies, especially from the viewpoint of occupational hazards (9-11). Although the toxicological procedures are well established there are several reasons why this approach is inadequate for our purposes.

Industrial exposure standards are usually determined by the American Conference of Governmental Industrial Hygienists. These standards, called "threshold limits," are based upon exposures of healthy adults to a single substance for a period not to exceed 8 hours followed by a recovery period of at least twice that long. In community air pollution from auto-

mobile exhaust, concentrations vary from hour to hour, but the exposure may be continuous, both in time and, for most persons, in place. Coming home from work does not mean an end of exposure to air pollution and may mean a great increase if the trip requires driving during peak traffic.

The extent to which exposure to one or more of the substances in automobile exhaust increases the effect of another is not known. Concern over this possibility is heightened by some examples of synergistic effects. Amdur (12) has shown the extent to which aerosols enhance the effects of SO₂ on the pulmonary airway flow resistance in guinea pigs, and Falk (13) has shown the effect of soots on deposition of carcinogens. Until further studies have clarified such interactions, it is necessary to suspect that components of exhaust may have synergistic effects.

While industrial exposures usually involve small numbers of relatively healthy people, community exposures affect, in varying ways, the entire population of a community, the sick with the well, the frail with the vigorous. In sufficient concentrations, exhaust from automobiles may lead to morbidity or even mortality in the sick and frail segment of the population whereas the same exposure might not noticeably affect healthy and vigorous persons. For persons with circulatory failure or with reduced competence of cerebral or myocardial circula-

tion, slight impairment of the oxygen transport function of the blood may have serious consequences. In addition to these people, two other groups are at unusual risk from communitywide exposure to auto exhaust. They are the workmen who experience a similar type of exposure while employed, and persons who inhale tobacco smoke. If a member of these multiple exposure groups is also ill, or has impaired health, then the hazard may be compounded.

Finally, we cannot assume that termination of exposure terminates risk of ill effects. In this connection, data on lung cancer reported in Eastcott's study of emigrants from Great Britain to New Zealand are revealing (14). He found that the duration of exposure to urban air pollution in Britain before emigration was significantly associated with rates of development of lung cancer observed many years later. Since cigarette consumption was similar in Great Britain and New Zealand, the evidence points toward atmospheric pollution as a factor in the causation of the disease.

It will take years to estimate accurately the possible delayed consequences of exposure of large numbers of persons to automobile exhaust fumes, but the possibility of harm exists and is difficult to evaluate by conventional toxicological methods.

Carbon Monoxide

The maximum carbon monoxide concentration reported in table 2 is 93.2 ppm, while the

average values were 15 to 36 ppm. Average concentrations of 4 to 20 ppm, with a maximum of 80 ppm, have been reported in British cities during smog (15). Similarly, an average of 28.9 ppm carbon monoxide in Detroit during heavy traffic has been reported, with a maximum of 80 ppm (16).

More is known about the mechanism of absorption and action of carbon monoxide than about any other noxious substances found in exhaust. This tasteless, odorless, colorless gas is 250 times as firmly bound to hemoglobin as is oxygen. It may be calculated that at equilibrium for every part per million of carbon monoxide reaching the lung, 0.16 percent of the body's hemoglobin is combined with carbon monoxide, and hence inactive. Roughton (17) has shown further that in the presence of carbon monoxide-hemoglobin compounds, oxygen is bound more firmly to hemoglobin, thus further impairing oxygen transport.

While no health damage has been attributed to carbon monoxide exposures below 100 ppm, the presumption that such levels inactivate a small amount of hemoglobin is inescapable. Gaensler and his associates (18) have shown that urban nonsmokers have a CO level corresponding to saturation of 0.62 to 1.24 percent of hemoglobin, while smokers have 3.1 to 7.8 percent. The public health importance of this lies in the certainty that smoking and exposure to automobile exhaust are so common that a very large number of persons are affected in such a way that up to 8 percent of their hemo-

globin is unavailable for oxygen transfer. Accurate predictions of carbon monoxide-hemoglobin levels from environmental measurements are complicated by the fact that some time is taken to reach equilibrium and this time varies with the activity of the subject.

In studies on the adaptation of eyes to darkness McFarland (19) demonstrated an impaired adaptability in older persons which was duplicated in young subjects when breathing gases deficient in oxygen or when exposed to low levels of carbon monoxide. The importance to automobile drivers of visual sensitivity at night is obvious. However, it has not been shown that exposure to automobile exhaust at the levels found on the freeways of a modern city impairs the adaptability of eyes to darkness or alters the exchange of vital respiratory gases, although this is a plausible inference.

Some idea of the possible exposures of drivers is obtained by sampling air in the driver's compartment of motor vehicles, as shown in table 3 (20).

Another way of stating the effect of carbon monoxide is that its inactivation of hemoglobin is similar to withdrawing the corresponding amount of blood from circulation. From this viewpoint a concentration of carbon monoxide of 100 ppm, when equilibrated, is associated with inactivation of about one-sixth of the body's circulating hemoglobin, equivalent in volume to about one pint of blood, with corresponding loss for other concentrations of carbon monoxide.

Nitrogen Oxides

During acceleration and cruising, automobiles emit appreciable quantities of nitric oxide. On mixing with oxygen, nitric oxide is oxidized to nitrogen dioxide, so that a mixture of these two oxides is found in the atmosphere. The concentration of nitrogen oxides in the open air may be 1 ppm at times when CO is 50 ppm.

The toxicity of nitrogen dioxide is based on its irritant properties, often delayed in onset. In cases of significant exposure, signs and symptoms of pulmonary edema have been noted hours to days later (21). Nitric oxide also forms a stable compound with hemoglobin in vitro, which, if it occurred in vivo, would make

the hemoglobin unavailable for transport of carbon dioxide and oxygen.

Nitrogen dioxide on dissolving forms some nitrite ion which is capable of reacting with hemoglobin to yield methemoglobin, also unsuitable for transporting respiratory gases. That this may occur under some circumstances is suggested by a report of methemoglobin levels of 2.3 to 2.6 percent in welders exposed to a mixture of gases including nitrogen oxides (22).

It is unlikely that toxic effects would occur solely from the levels of nitrogen oxides found in places with air pollution due to automobile exhaust. But the similar effect of the reaction of hemoglobin with carbon monoxide and with nitrogen oxides lends greater significance to studying the latter.

Lead Compounds

Nearly all gasoline used in automobiles contains lead tetraethyl, up to as much as 3 ml. per gallon. This lead is mostly discharged through the exhaust to the atmosphere, and this fact has caused much concern over the past 25 years as to the possible effects of lead on health. Lead occurs mostly in the particulate form, and a maximum concentration of 16 micrograms per cubic meter has been reported by Cholak and others in Los Angeles with average values of 7 micrograms per cubic meter (23) during a 4-month period, August-November 1954.

In general, analyses of urban air show lead concentrations which are low in relation to the amount of lead burned in gasoline. This may

Table 3. Levels of carbon monoxide in parts per million found in compartments of drivers of motor vehicles in California

Parts per million	Number of vehicles	Percent of vehicles
0-49-----	1, 014	91.8

be explained by the fact that the particle size of the exhausted lead ranges from 0.01 micron to several millimeters in diameter, and the large particles can be expected to settle rapidly when exhausted into open air. Moreover, high-speed driving tends to increase the number of heavy particles, and also tends to clean out the exhaust system of lead previously deposited during the light duty, stop-and-go driving conditions (24).

Estimating the retention of lead in the body is complicated by the problem of particle size and composition. Generally speaking the smaller (submicron) particles impinge on the deeper portions of the lung, where they may be rapidly absorbed, while larger particles are more likely to impinge on the mucous layer of the upper portion of the airway and subsequently be swallowed. Such a route is associated with loss of most of the lead in the feces.

One feature of the toxicology of lead indicates that its effect might be related to that of carbon monoxide and of nitric oxides. In chronic lead poisoning, there is found a low-grade anemia and also increased fragility of red blood cells; this may tend indirectly to impair transportation of respiratory gases.

When considered apart, lead exposure from observed levels in Los Angeles and other cities is not toxic, but lead exposures are so common in industry and in garages that the small and persistent increment in exposure associated with auto exhaust may be sufficient to render an otherwise tolerable lead burden a toxic one in a few persons.

Hydrocarbons

Although "hydrocarbons" have been classed as a group in table 2, it is apparent that the group includes many compounds such as paraffins, olefins, aromatics, cycloparaffins, and others. The particular mixture in automobile exhaust depends in part on the fuel used and in part on the way the motor vehicles are operated. The total hydrocarbon concentration in the open air seldom exceeds 2 ppm, hence the concentration of individual compounds will be much less than that. At these low concentrations, only those having known physiological activity are of concern.

One group of hydrocarbons of particular interest includes such compounds as 3,4-benzpyrene which under experimental conditions may produce cancer in animals. This compound, along with others of similar chemical constitution, has been qualitatively identified in automobile exhaust in trace amounts (25,26). Although polynuclear hydrocarbons produce tumors when painted on the skin of susceptible animals, their inhalation has resulted in no experimental lung cancers. Experimental tumors can be produced if the lung's mucosa is damaged, for example, by a transfixion suture soaked in the carcinogen or by a hooked capsule containing the substance which is retained in the bronchus of an experimental animal (27). From such studies one is led to the hypothesis that carcinogenesis occurs on the basis of damage to the mechanisms protecting the underlying tissues.

The possibility that these trace quantities do in fact have a relation to the occurrence of lung cancer is a debatable point, and one on which additional research is necessary. Moreover, even if 3,4-benzpyrene is a cause of lung cancer, it is present to a much greater extent in coal smoke than in automobile exhaust. Communities in which coal is used as a major fuel could expect to find far more 3,4-benzpyrene arising from coal burning than from combustion of petroleum fuels. For example, Los Angeles (28), where no coal is burned, has been found to have 3.3 micrograms of 3,4-benzpyrene per 100 cubic meters of air, while in London (29) values up to 47 micrograms per 100 cubic meters have been reported.

Interactions of Exhaust Components

On the west coast, where weather conditions may lead to poor dispersal of automobile exhaust, and where there is an abundance of solar radiation, an interaction of nitrogen oxides and hydrocarbons occurs. This results in the obnoxious mixture which we call photochemical smog. The principal products are ozone and organic intermediates, some of which irritate eyes and damage plants. Ozone sometimes reaches a concentration of 0.5 ppm or more.

It is known that ozone is a highly irritating

globin is unavailable for oxygen transfer. Accurate predictions of carbon monoxide-hemoglobin levels from environmental measurements are complicated by the fact that some time is taken to reach equilibrium and this time varies with the activity of the subject.

In studies on the adaptation of eyes to darkness McFarland (19) demonstrated an impaired adaptability in older persons which was duplicated in young subjects when breathing gases deficient in oxygen or when exposed to low levels of carbon monoxide. The importance to automobile drivers of visual sensitivity at night is obvious. However, it has not been shown that exposure to automobile exhaust at the levels found on the freeways of a modern city impairs the adaptability of eyes to darkness or alters the exchange of vital respiratory gases, although this is a plausible inference.

Some idea of the possible exposures of drivers is obtained by sampling air in the driver's compartment of motor vehicles, as shown in table 3 (20).

Another way of stating the effect of carbon monoxide is that its inactivation of hemoglobin is similar to withdrawing the corresponding amount of blood from circulation. From this viewpoint a concentration of carbon monoxide of 100 ppm, when equilibrated, is associated with inactivation of about one-sixth of the body's circulating hemoglobin, equivalent in volume to about one pint of blood, with corresponding loss for other concentrations of carbon monoxide.

Nitrogen Oxides

During acceleration and cruising, automobiles emit appreciable quantities of nitric oxide. On mixing with oxygen, nitric oxide is oxidized to nitrogen dioxide, so that a mixture of these two oxides is found in the atmosphere. The concentration of nitrogen oxides in the open air may be 1 ppm at times when CO is 50 ppm.

The toxicity of nitrogen dioxide is based on its irritant properties, often delayed in onset. In cases of significant exposure, signs and symptoms of pulmonary edema have been noted hours to days later (21). stances is very difficult because of the sensitivity of frail or ill individuals, the indeterminate period of exposure, the effect of agents in combination, and the cumulative effect of exposure from other sources, such as cigarette smoking.

The hazard of automobile exhaust to the population of a large community will depend, among other things, on the extent and way that vehicles are used, and the meteorology of the area.

In the absence of effective control for air pollution from automobile exhaust, the public health hazard should be evaluated.

substance, and is capable of producing clinical signs of pulmonary irritation. Repeated daily exposures of animals to 1.0 ppm for about a year produced fibrosis of the lung in some species. Recently the hygienic standard for industrial exposure was reduced from 1.0 ppm to 0.1 ppm by the American Conference of Governmental Industrial Hygienists.

Of all the substances mentioned, ozone is the only one in Los Angeles which exceeds the hygienic standard for industrial exposure of 0.1 ppm. However, studies to determine whether respiratory disease or deaths in Los Angeles are more common on days with high air pollution levels have not so far demonstrated such an effect. In a review of the hazards of ozone, Stokinger (30) states that "if the response of the human lung to ozone may be assumed to be similar to that of the animals tested in these studies, one might reasonably conclude that no acute effects on human beings would be expected from ozone exposures occurring in Los Angeles-type smog, owing to the often repeated exposures to very low grade ozone concentrations of the order of a few tenths part per million." Nevertheless, the use of pulmonary function tests on large numbers of persons may assist in reaching a conclusion about the effect of ozone or other irritants on respiratory function.

In addition to ozone, reactive organic intermediates, including free radicals, are formed (31). Whatever the compounds may be that cause eye irritation, it has been proved that these compounds are produced by irradiation of automobile exhaust.

It remains to be shown, however, whether the same compounds irritate the respiratory tract or whether irritation by inhaled substances plus inhaled carcinogens could produce cancer of the lung. More data are needed on the exact nature of the reactions, the concentration of the products, and their physiological effects.

Discussion

Two important effects of the known constituents of automobile exhaust are (a) the conversion of hemoglobin into a relatively stable, inactive form which impairs the efficiency of the blood and circulation in transporting the respiratory gases, oxygen and carbon dioxide, and

(b) the production of respiratory tract irritation or pulmonary edema, either of which interferes with the transport of gases between the blood and the external atmosphere. The severity of both of these effects on individuals would depend on concentrations, length of exposure, age and vigor of the subjects, and other conditions. Concentrations found in the Los Angeles atmosphere have not been shown to interfere with gas transport mechanisms.

We have described what seems to be a potential hazard. To demonstrate whether an actual hazard exists, it will be necessary to combine measurements of exhaust constituents in the atmosphere with estimates of the impairment they produce. For example, measurements should be made of the proportion of hemoglobin inactivated by carbon monoxide and nitric oxides in large numbers of persons exposed to air polluted by automobile exhaust.

We suggest that hygienic standards for automobile exhaust in a community should be set at levels which will produce no health effects on the most susceptible group of persons in the community, defined in terms of age or health status. Among the groups to be considered would be those ill with impaired cerebral or myocardial circulation or impaired pulmonary function.

It is of interest that the public health problems of automobile exhaust have been recently surveyed in the U.S.S.R. with essentially the same conclusions as were independently reached by us (32).

Despite the difficulties, all possible means should be taken to control atmospheric pollution from automobile exhaust. At present it seems unlikely that control devices for automobile exhaust will eliminate all of the potentially harmful substances. Until there is complete control, potential hazards should be recognized and efforts made to assess damage.

Summary

Of the substances which occur in automobile exhaust and their reaction products, hygienic standards have been established for industrial exposure to carbon monoxide, nitrogen dioxide, lead, and ozone. Establishing a full set of levels for community exposures to these sub-

A Baseline Survey Of Pennsylvania Sanitarians And Their Backgrounds

HENRY R. O'BRIEN, M.D., M.P.H.

IN the late spring of 1956, an investigation of the background of sanitarians, which began in Maryland and Puerto Rico in 1954 (1), was extended to Pennsylvania. On both occasions, a training program was in progress. It was felt that the development of further plans would be aided by a knowledge of the situation, in particular, the number of sanitarians, their ages, educational background, salary, length of service, and so on.

The same questionnaire was used in 1956 as in 1954. The blanks were circulated by the divisions of sanitation in Philadelphia and Pittsburgh and by our regional sanitarians to State employees and full-time local sanitarians. In these groups the coverage was practically complete; the one or two local sanitarians who may have been overlooked would not invalidate the findings. In private industry, however, only a beginning was made; this is practically a dip sample.

In most places in the United States, certainly in Pennsylvania, three groups are providing environmental health service: the sanitary or public health engineer at the top, a sanitary inspector in the ranks, usually local, and a new person, the sanitarian, who has now appeared between the other two. The third group is growing in numbers, training, and functions; the second is probably shrinking.

The changes are so rapid that it is valuable to have a record of this study as a baseline, not only as a help in planning training but also for later comparison to measure progress. Many new people are being appointed, with much

more training, to work on new programs or on old programs in new ways. Many of these 1956 findings no longer obtain, but it is essential to have them on record or we shall not know in 1961 or 1966 just how far we have progressed.

This paper considers the "sanitarian" and the "sanitary inspector" together, for the borderline is not yet definite. Staff members and their supervisors are included, but not (a) those with engineering degrees or those doing strictly engineering work, (b) veterinarians concerned with diagnosis or treatment of sick animals, (c) employees of other State departments, (d) Federal workers, (e) laboratory technicians, or (f) laborers.

In all, 312 replies to the questionnaire were received and tabulated, including 91 from the State, 51 from Philadelphia, 43 from Pittsburgh, 107 from smaller local departments of health, and 20 from private industry. Next to public health nurses, sanitarians make up the largest group in public health in Pennsylvania.

Some of the findings of the questionnaire are included in the tables and discussion below. The conclusions from these data are limited in scope, for the questions are few and the numbers are small. However, trends are evident.

Population Ratio

First, we may ask the number of sanitarians employed by health departments in relation to 1956 population estimates. In Pittsburgh, 1 sanitarian was at work per 15,700 persons in the population. In Philadelphia, the ratio was 1 to 42,700 and in the rest of Pennsylvania, counting both State and local sanitarians, 1 to 42,000. In Baltimore and Puerto Rico in 1954, on the other hand, the figure was 1 to 10,000 and in upstate Maryland 1 to 20,000. These proportions are enough to make us consider whether in much of Pennsylvania sanitarians are too few, although they do not reflect the number of sanitarians in private employment, the level of sanitation practice, or the effects of climate or dispersion of population.

Age, Education, and Salary

The age and education of Pennsylvania's sanitarians are shown in table 1. The median

Dr. O'Brien is director of professional training in the Pennsylvania State Department of Health, Harrisburg. This paper was read at the Annual Health Conference, University Park, Pa., on August 19, 1958.

Stebbins New Chairman of PHR Board of Editors

Dr. Ernest Lyman Stebbins, dean of the Johns Hopkins University School of Hygiene and Public Health for the past 13 years, is the newly appointed chairman of the Board of Editors of *Public Health Reports*. He succeeds Dr. Edward G. McGavran, dean of the University of North Carolina School of Public Health, who has served as chairman since 1952.

Dr. Stebbins entered the public health field in 1931 as an epidemiologist with the Virginia State Department of Health after completing internship and residencies at Clara Barton Hospital in Los Angeles and Presbyterian Hospital and the University Clinic in Chicago.

In 1934, he transferred to the New York State Department of Health and was appointed New York City Health Commissioner in 1942. In 1945, he received the Lincoln Award for distinguished service to the city. From 1940 to 1946 he was a professor of epidemiology at Columbia University.

He served as a medical director with the Public Health Service during the war and retains status as a reserve officer.

Dr. Stebbins is a fellow of the American Medical Association and the American Public Health Association; 1958-59 president of the Advisory Board of Medical Specialties; chairman, American Board of Preventive Medicine; and former president of the American Epidemiological Society.

Publications by Dr. Stebbins include, in addition to reports of scientific research, "Epidemiology and Social Medicine—Social Medicine: Its Derivations and Objectives," Commonwealth Fund, 1949, and "Introduction to Public Health," written with Dr. Harry S. Mustard.

After being graduated by Dartmouth College in 1926, Dr. Stebbins received his medical degree from the Rush Medical School of the University of Chicago in 1929. His master's degree in public health was earned at Johns Hopkins University School of Hygiene and Public Health in 1931.

figures follow the social trends of past generations, when the education of many boys ended with grade school. Later, high school was the accepted stopping point. In the Maryland study, the findings were much the same, but employment of college graduates for this work began in Maryland a little earlier than in Pennsylvania.

The educational breakdown for the different agencies appears in table 2. Three-fourths of the group had finished high school; Philadelphia and private industry made the best showing. One-third graduated from college, Philadelphia and private industry again leading, with local workers far in the rear.

If we look at sanitarians employed only in the last 4 years, a different picture appears. Educational standards went up. Eleven-twelfths of the group had finished high-school, and two-thirds, college. This is an indication of what happens today. These Pennsylvania figures in turn are higher than those in the 1954 study.

The major undergraduate courses taken are shown in table 3. Three-fourths (78 percent) followed courses in the biological sciences. Pittsburgh and private industry had a predilection for agricultural graduates, who were still more popular in Maryland.

The current in sanitation today runs strongly

¹ Some of these had been to college, but did not graduate.

with a master's or bachelor's degree in public health do not need this basic course, but the rest do. Table 6 shows a substantial need for such a course, particularly in the local and industrial groups.

Everyone needs the information and the stimulation of a short course in his field, yet only 87 of the 312 attended even one short course in 1953, 102 in 1954, and 118 in 1955. Philadelphia made the best showing of any of the agencies. But some workers in each category, as table 6 shows, attended not one short course in these 3 years. That is withering on the vine indeed. Attendance was especially low among the sanitarians in the smaller local health departments.

It is evident that the local sanitarians are a large body of health workers, usually insufficiently trained, with less formal education, and paid lower salaries than their associates in State or private industry jobs. However, these local people are natural aides for overloaded State

sanitarians. A State sanitarian in close touch with all local workers in his area can help and be helped by such association. It is clear that training for local sanitarians is a sound and necessary investment.

The sanitarians of private industry, barely touched in this study, warrant further coverage in the future.

Conclusion

The figures presented here should be studied by all of us for what they suggest, as a basis for planning and cooperation.

A similar study in other States would prove valuable.

Heart-Sound Recording of Chicago School Children

The heart sounds of 40,000 public elementary school children in Chicago are being recorded in a new study launched on April 20, 1959. The study is being sponsored by an interagency committee. Ultrasensitive tape recording equipment, developed under Chicago Heart Association leadership, is being used; the heart sounds are being recorded on the tape for subsequent analysis. The Public Health Service is providing technical assistance and support.

The objective is to test this mass screening method as a rapid and practical means of finding individuals with abnormal heart sounds. The heart-sound recorder is believed to be as effective as the stethoscope.

In the study, which is scheduled to last about 18 months, at least two cardiologists will listen to all heart-sound recordings, and the findings of each specialist will be checked against the other. Parents of children who need further study will be notified, and secondary screening by physician examination will be performed.

Schools selected represent a cross section of the city's varied population groups. Guiding the project with the Service is a committee of representatives from the following Chicago groups and institutions: the Board of Health, the Board of Education, the Medical Society, the Heart Association, and local universities. A physician from the Chicago Heart Association is serving as project coordinator.

in favor of the biology major. In 1954 the authors asked if anyone really knew whether this was well founded. Today we are emphasizing the importance of the social sciences. Will this be reflected in new requirements?

Table 4 shows that, by and large, educational background is reflected in the paycheck. Differences would probably be greater if it were not that those with less education have been longer on the job, and experience and native ability are valued as well as schooling.

Among the different agencies, local posts tend to pay less than State positions, and private industry appears to pay more than government. It is only fair to say that salaries, especially for State positions, have risen markedly since 1956.

Service and Training

In table 5, we note that more than a third of the sanitarians came to their present employers less than 3 years before this study. The proportion was largest in Philadelphia and in the State and was fairly even in the others. Philadelphia had only two who had been there more than 19 years.

The period of "service with present employer" is usually the same as "total service in sanitation." Sanitarians do some moving among jobs, but not a great deal.

A course of field training in basic sanitation of from 9 to 12 weeks is considered a standard in the preparation of sanitarians, much like the academic year of public health nursing. Those

publications

Directory of Local Health Units. *PHS Publication No. 118; Revised 1958; 75 pages; 30 cents.*

Formerly entitled "Directory of Full-Time Local Health Units," this publication lists the name of each health unit, health officer or administrative head, and headquarters location. Included for the first time are all local areas which State health officers considered organized to provide public health services, irrespective of whether the health officer serves full time or part time, and whether medical, nursing, and sanitation public health services are available at all times.

Part-time employment of a health officer or administrative head is indicated. In addition, the absence of medical, nursing, and sanitation personnel is shown.

The National Mental Health Program and the States. *PHS Publication No. 629; 1959; 13 pages; 10 cents.*

For organizations and individuals interested in community mental health activities, this pamphlet describes grant-supported programs of the National Institute of Mental Health, Public Health Service. It sketches their operation and tells how they affect the States. Mental health consultants and State mental health authorities are listed.

The Mentally Retarded Child at Home. *Children's Bureau Publication No. 374; 1959; by Laura L. Dittmann; 99 pages; 35 cents.*

This manual for parents, approaching the problem of retarded children from the standpoint of sequences of growth and development, stresses the ways in which these children are like other children.

Included are suggestions for toilet training, dressing, cleanliness and manners, discipline, speech, play, and group experiences for the young retarded child. The manual also lists toys and equipment for home

play and provides parents of young children with long-range guides to problems which may arise during the retarded child's school days and his adjustments in adolescence.

Aging. A review of research and training grants supported by the National Institutes of Health. *PHS Publication No. 652; 1958; by G. Halsey Hunt and Stanley R. Mohler; 50 pages; 35 cents.*

A summary of the extramural research and training activities in aging conducted by the National Institutes of Health, Public Health Service, this review describes each of the categorical programs of the seven institutes and the general program of the Division of General Medical Sciences.

It also lists laboratories throughout the United States where research in aging is being conducted.

Sewage Treatment Works Contract Awards, 1952-1957. *PHS Publication No. 633; 1958; by William H. Abbott and Lewis C. Hudson, Jr.; 93 pages; 50 cents.*

This publication summarizes data originally presented in annual reports of public sewage treatment plant construction for the years 1952 through 1957 (PHS Publications Nos. 291, 409, 453, 488, 549, and 608). New tabulations show contract awards for the 6 years, by population size groups, by contract size groups, by drainage basins, and by States. Lists of individual projects, by year and by State, appear in an appendix.

Scientific Translations. A guide to sources and services. *PHS Publication No. 514; Revised 1959; 19 pages; 15 cents.*

Foreign and domestic institutions maintaining files of translations and offering translating services are described briefly and their publications are noted.

Periodicals in complete or partial translation are listed with subscription information. Russian journals in cover-to-cover translation are arranged alphabetically by both English and Russian title.

Information about professional organizations for translators and selected references on various aspects of translating are included.

Poultry Ordinance. *PHS Publication No. 444, Supplement No. 1; 1958; 9 pages.*

This supplement contains recommended provisions on antemortem and postmortem inspection of poultry for wholesomeness, for use by interested States and municipalities in conjunction with other provisions of the ordinance published in 1955. The supplement also includes some revised and additional labeling requirements and definitions necessary in relation to the inspection provisions.

When You Adopt a Child. *Children's Bureau Folder No. 13; Revised 1958; 28 pages; single copies 15 cents, \$10 per 100.*

Counseling prospective adoptive parents to give up all idea of finding a child without help, the booklet answers questions they might ask. It also reviews the questions which will be asked by the caseworker. A new section offers advice on citizenship and birth certificate needs of the child adopted from abroad.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications other than its own.

Signs

and

Symptoms

of trends in public health

"Understanding Aphasia," a 50-page booklet written by Martha L. Taylor, New York Institute of Physical Medicine and Rehabilitation, is designed to help families understand loss of speech and to acquaint them with speech rehabilitation.

" "

When the Chehalis Fluoridation League in Chehalis, Wash., offered \$1,000 reward in 1955 to anyone who could prove that fluorides in 1 ppm concentration had caused any ill effect to anyone anywhere, they were sued by Dr. F. B. Exner. His evidence was based on testimony of a man and wife who had severe dental fluorosis and who had lived in areas where the water supply was presumed to be less than 1 ppm in the public water supply.

Testimony revealed that the dental enamel of this couple had developed prior to the first studies of fluoride levels in water supplies, and that the water used by these people when they were children must have been in excess of 2 ppm. Dr. Exner lost his case and his appeal.

" "

Many members of insured medical plans waste benefits because they are inadequately informed and without guidance, reports the Columbia University School of Public Health and Administrative Medicine.

" "

Sterilizing male mosquitoes by irradiation with cobalt-60 has proved an effective means of reducing the population of malaria-carrying insects, report entomologists from the U.S. Department of Agriculture.

A 389-page study of the Windsor (Canada) medical services has been published by Harvard University Press. The book, "Comprehensive Medical Services Under Voluntary Health Insurance," was written by Benjamin J. Darsky, Dr. Nathan Sinai, and Dr. Solomon J. Axelrod, all with the Bureau of Public Health Economics, University of Michigan School of Public Health.

" "

Phreatophytes (thirsty plants and trees) drink 25 million acre-feet of water annually, reported Dr. D. L. Klingman and F. L. Timmons before the December convention of the American Association for the Advancement of Science.

" "

The Community Services Committee, AFL-CIO, has sent several letters to its local community services committees on health matters. One said, apropos of the Murray-Green Award to Dr. Salk, "The best gift we can give Dr. Salk is the full use of his vaccine." It recommended joint union-management, local health department, and county medical society cooperation in a mass inoculation program on a plantwide basis and in other relevant activities.

Local community services committees were urged also to advance fluoridation.

Since professional workers are "underpaid, underpraised, and unheralded," the committee suggested that community chests allocate 1 percent of total funds raised annually for scholarships. Forums on health problems were suggested as well as further development of public health departments.

Deaths caused by measles during 1957 outnumbered deaths caused by poliomyelitis for the first time since 1944. There were 410 deaths from measles and 220 from poliomyelitis.

" "

The Food and Nutrition Board has approved for publication a report entitled, "Evaluation of Protein Nutrition with Emphasis on Amino Acids Proportionalities," which presents a comprehensive background for critical consideration of the addition of specific amino acids to cereal foods for improvement of protein quality.

A report of the board's Food Protection Committee, with reference to the 1958 amendment to the Federal Food, Drug, and Cosmetic Act, entitled "Food Packaging Materials—Their Composition and Uses," is also approved for publication.

" "

Admissions to schools of professional and practical nursing reached a new high in 1958, according to the National League for Nursing, New York. An estimated 46,600 students entered basic professional nursing schools, compared with 44,281 the preceding year. Some 20,000 began training for careers in practical nursing, compared with 16,710 the year before.

" "

A new booklet, "Your Future," is offered without charge by the Office of Mental Education and Information, Department of Mental Hygiene, Albany, N.Y. Its purpose is to stimulate constructive thinking about the later years.

" "

The automobile insurance industry has set up an Institute for Highway Safety with annual appropriations of \$1,000,000.

" "

The Connecticut Heart Association, in cooperation with the pharmaceutical industry, the retail druggists, and the medical profession, has made it possible for anyone who has had rheumatic fever to purchase penicillin at a discount to prevent recurrence. The price is \$15 per year. Ordinarily a yearly supply costs several times that amount.

A summary of the extramural research and training activities in aging conducted by the National Institutes of Health, Public Health Service, this review describes each of the categorical programs of the seven institutes and the general program of the Division of General Medical Sciences.

It also lists laboratories throughout the United States where research in aging is being conducted.

Sewage Treatment Works Contract Awards, 1952-1957. *PHS Publication No. 633; 1958; by William H. Abbott and Lewis C. Hudson, Jr.; 93 pages; 50 cents.*

This publication summarizes data originally presented in annual reports of public sewage treatment plant construction for the years 1952 through 1957 (PHS Publications Nos. 291, 409, 453, 488, 549, and 608). New tabulations show contract awards for the 6 years, by population size groups, by contract size groups, by drainage basins, and by States. Lists of individual projects, by year and by State, appear in an appendix.

Scientific Translations. A guide to sources and services. *PHS Publication No. 511; Revised 1959; 19 pages; 15 cents.*

Foreign and domestic institutions maintaining files of translations and offering translating services are described briefly and their publications are noted.

Periodicals in complete or partial translation are listed with subscription information. Russian journals in cover-to-cover translation are arranged alphabetically by both English and Russian title.

Information about professional organizations for translators and selected references on various aspects of translating are included.

Poultry Ordinance. *PHS Publication No. 444, Supplement No. 1; 1958; 9 pages.*

This supplement contains recommended provisions on antemortem and postmortem inspection of poultry for wholesomeness, for use by interested States and municipalities in conjunction with other provisions of the ordinance published in 1955. The supplement also includes some revised and additional labeling requirements and definitions necessary in relation to the inspection provisions.

When You Adopt a Child. *Children's Bureau Folder No. 13; Revised 1958; 28 pages; single copies 15 cents, \$10 per 100.*

Counseling prospective adoptive parents to give up all idea of finding a child without help, the booklet answers questions they might ask. It also reviews the questions which will be asked by the caseworker. A new section offers advice on citizenship and birth certificate needs of the child adopted from abroad.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications other than its own.

ECHOES from Public Health Reports

RIBOFLAVIN DEFICIENCY IN MAN (ARIBOFLAVINOSIS)¹

By W. H. SEBRELL, *Surgeon*, and R. E. BUTLER, *Passed Assistant Surgeon, United States Public Health Service*

Many of the early writers on pellagra (1) recognized that certain symptoms of the disease sometimes occurred without the skin lesions, and the term "pellagra sine pellagra" was introduced to designate these symptoms. In 1912 Stannus (2), in describing pellagra in Nyasaland, particularly noted lesions in the angles of the mouth which he called "angular stomatitis." Similar lesions with various other symptoms have been described by numerous other observers. In 1928 Jenner Wright (3) in Sierra Leone described lesions at the mucocutaneous junction associated with nervous system lesions which were cured by cod liver oil and yeast. Lesions which appear to be similar in many respects have been seen by Fitzgerald (4) (1932) in an Assam prison; Moore (5) (1934) in school children in Nigeria; Landor and Pallister (6) (1935) in the prisons of Singapore and Johore, and Aykroyd and Krishnan (7) (1936) in school children in South India.

As early as 1918 Goldberger, Wheeler, and Sydenstricker (8) suggested that two different dietary factors may be involved in pellagra, and in 1925 Goldberger and Tanner (9), in their experiments with casein, noted that the patients developed a dry, glazed vermilion border of the lips, erosions at the angles of the mouth, reddening of the lips, and seborrhea about the nose. They diagnosed these lesions as pellagra sine pellagra. They also saw in some a pasty, caseous accumulation in the nasolabial folds which cleared up when dried yeast was added to the diet.

DECEMBER 1, 1939, pp. 2121-2131

Dr. W. H. Sebrell and Dr. R. E. Butler concluded that a diet low in riboflavin caused a condition known as "pellagra sine pellagra," since the condition disappeared with the administration of synthetic riboflavin. Dr. Sebrell and others later (*Public Health Reports* 56: 510-519, Mar. 14, 1941) specified a daily riboflavin requirement of an adult.

A Health Program for Children in Day Care Services

HUGH CHAPLIN, M.D., and HAROLD JACOBZINER, M.D.

THE NEW YORK CITY Department of Health for the past 7 years has arranged to look after the health of children of low-income families at centers established to provide day care for small children. Introduced only at each center's request, a comprehensive program of health examinations, immunization, and health counseling is now offered at 70 of 76 centers in the city.

These centers are supported by the New York City Department of Welfare, which shared in a series of planning sessions with the health department. Health and welfare officials continue to consult periodically in appraising changing needs and achievements in the centers.

Each center cares for from 40 to 75 children aged 3 to 6 years. About half have only one parent. The children may arrive at the center between 8 and 8:30 a.m. and remain until 5:30 to 6 p.m., 5 days a week, 12 months a year.

The time is fortunately long past when the centers provided mere custodial care by untrained staffs. For the past 15 years all day care services in New York City for children under 6 years of age have been subject to the standards of the New York City Sanitary Code, Section 198. These standards deal with fire and building safety, adequate space per child, the number and qualifications of teachers, types of

educational and play materials and equipment, and the program of indoor and outdoor activity, as well as health requirements. The division of day care and foster homes in the New York City Health Department is responsible for seeing that the centers qualify for a license.

The great majority of the centers are located in excellent quarters in new housing projects. The space is arranged especially for the particular needs of a child care center, and furnishings and equipment are carefully planned for small children. All provide classroom space indoors and play yards outdoors. Teachers must be qualified as educators for preschool children. The director of a center often holds a master's degree in education.

The objective is to provide wholesome, constructive, and enjoyable activities for children, under skilled and understanding guidance with a minimum of regimentation. The centers aim to develop independence in the child and to teach him how to live happily with other children and adults. There is enough supervision to preserve the value of necessary control and encourage self-discipline. Visitors to the centers have said that their principal impression is that the children are relaxed and happy.

The sanitary code requires that each child have a physical examination prior to admission and every 6 months thereafter while attending the center. Records of the examinations must be kept in the centers. Vaccination against smallpox and DTP immunization are also necessary before admission, and daily inspection of the children is required to help ex-

Dr. Chaplin is pediatric consultant in the division of day care and foster homes, and Dr. Jacobziner is assistant commissioner, New York City Department of Health.

clude contagion and detect other illnesses. Each staff member who comes in contact with the children must have at the time of employment and every 2 years thereafter a physical examination, including a chest X-ray and any other indicated laboratory tests.

The licensing requirements have undoubtedly raised the standard of day care in this city. However, the requirements are minimal rather than ideal, and they are often barely satisfied. For example, in the past physicians often submitted reports of physical examinations with little significant information. This deficiency could have been due to lack of real parental interest in a thorough examination. Or it is possible that the physician did not realize the importance of his findings to the center's staff.

In an effort to raise health conditions to the optimum, officials of the health and welfare departments began to talk about health services for the city's day care centers in 1947. The first comprehensive health program was tried in 1952.

Principles and Components

A basic principle of the health program is that it is to supplement, not replace, the services of the family physician. The program includes health examinations for the children, immunizations whenever due, and conferences with the parents. The preadmission and the 6 months' examinations, as well as special examinations requested at any time by the center's director, all may be done at the center. However, parents are urged to obtain as many services from their family physician as they wish, and the center's health services are then adjusted to the needs of the individual child.

Another principle is that a parent must always be present when a child is examined. If necessary, parents take time off from work for this purpose. Presence of a parent is required so that a pertinent history can be obtained and the recommendations of the physician and nurse imparted directly. Maintenance of the child's health and development of his total personality are not isolated incidents but are significantly dependent on the health of the family and of the community. Therefore, the health services must be family centered and family oriented. It

is unwise and impractical to view the child as separate from his family and from the community of which he is a part.

The Health Team

Health services at each center are provided by the director, a counselor from the welfare department to take family histories, a physician, and a nurse. The physician is usually assigned to a center for two or three 3-hour sessions each month. The nurse is present at each of these sessions for conferences with the parents. At an extra session, she prepares for the next examining period, determining which children are due for an examination or an immunization injection, checking the health records, and investigating the general health status of the children. She also determines how well the parent has carried out the recommendations of the physician.

Practicing physicians are selected for the program and supervised by a pediatric consultant to the department of health. They are chosen not only because they can be counted on to do thorough health examinations but quite as much because of their sympathetic understanding of the child in his relations with family and associates and their knowledge of growth and development in the child. Participating are approximately 40 physicians, the majority women, some serving as many as 4 centers and others only 1. Six are certified by the American Board of Pediatrics. All have had some formal training in pediatrics.

Nursing service is provided either by the department of health or by one of the approved visiting nurse services.

Health Examination

The health examination is conducted in a leisurely manner and with care. All clothing except the underpants is removed. The children are examined sitting, standing, and lying down. They are referred to appropriate agencies promptly for the treatment of any adverse conditions found.

A special set of eye examinations is used to help the physician rule out anatomical eye defects. Children are screened for visual defects by the educational staff who are instructed in techniques by health department consultants.

. . . wholesome, constructive, and enjoyable activities . . .

If the reports of the physician's examination or of the screening test suggest any abnormality, the physician refers the child to an eye specialist for a complete examination.

Routine health problems of the children are of course handled directly by the center physician. But more serious or complicated problems are first discussed at a case-study conference of the whole health team after each member has examined or interviewed the child with the problem in mind.

Health Counseling

If the health examination and immunizations were all that were included, it is possible that other types of services would prove quite as satisfactory. The program includes, however, a feature that makes it particularly valuable and perhaps unique. This is health counseling. The physician listens to the parent, who must be present at the examination, even as he would

in his office. The nurse not only explains to the parent how to follow the physician's recommendations but also has ample opportunity to discuss many other matters on which the parent may need guidance and reassurance. At the director's request, both physician and nurse once or twice a year attend the monthly parents' meetings, at which they discuss general health questions informally.

Counseling is extended to the teachers, both through personal conferences about special children and at teachers' staff meetings. Individual situations, however, are not discussed at staff meetings.

The nurse also meets at least once a year with the teacher of each child. Affording an opportunity for an exchange of information between nurse and teacher, this conference is intended to insure that children with health problems are referred to appropriate services and that referrals are followed up.

Ancillary Activities

In addition to the regular program, the center health team cooperates in the effort of the health department to promote safety and prevent accidents among children. Physicians and directors report on a designated form to the health department all serious accidents occurring to the children under supervision. Also each director, physician, and nurse has been provided with what might be called a "safety library," which consists of five or more reprints describing how accidents occur and what to do to prevent them. The material is intended for use in counseling with parents or teachers.

Still another part of the center health program is the preparation of the school health form, which is completed to be forwarded to the grade school where the child will be enrolled. The physician fills out the form at the final periodic health examination. Providing this information for the public schools saves considerable time and effort on the part of the physicians of the bureau of school health, as the record stays with the child through his school career.

Orientation and Installation

Early in the development of the health program, we recognized the need for careful advance planning and preparation for installation in a particular center. The center staff, as well as others who are to complete the health team, must be thoroughly oriented as to the aims of the program and their individual duties. To accomplish this important task, the following procedures were worked out:

Action is initiated by the lay board of a child care center through a request to the health department for information. A meeting is then held at the center. Present are members of the lay board, the director of the center, the educational consultant from the department of welfare, a supervisor from the nursing organization that is to provide the public health nurse, and the pediatric and nursing consultants from the division of day care and foster homes. The health department consultants describe the program in detail, and thorough discussion is encouraged.

After this meeting, if the lay board wishes to adopt the program, it must request it in writing from the department of health.

On receipt of the request, the health department arranges a second meeting at the center which actually launches the program. In addition to those at the first meeting, the new center physician and nurse, the department of welfare counselor, and the local district health officer of the health department are present. Every detail of the program is discussed so that each member of the health team will have the opportunity to clarify in his mind his own duties and his relation to other team members.

About 6 months after the program is started, the pediatric and nursing consultants together visit an examination session to evaluate it and to discuss any matters not clearly understood by any member of the center's health team. Even though supervision is continuous, a flexible policy is favored and changes in the program to meet local needs are encouraged, so long as they are consistent with the basic philosophy.

A day care center must meet certain physical requirements before it can participate in the health program. There must be adequate space so that the physician can satisfactorily conduct his examination. The room need not be large, but it must be well lighted and heated during the winter and have proper ventilation. There must be running water nearby and an electrical outlet into which a small stove for sterilizing syringes and needles can be plugged. There must be another room nearby for the nurse-parent conferences.

Another requirement is that the director provide an assistant for the examination sessions, preferably a teacher. The nurse will be counseling with parents and cannot assume responsibility for the administrative phase of the examining session.

Less Than Perfection

It would of course be unrealistic to expect that the health program would operate perfectly in every detail. On the contrary, flaws were expected, and they have indeed appeared.

Perhaps our greatest difficulty is to assure satisfactory teamwork. We are attempting to

. . . nurse-parent conference . . .

. . . thorough health examination . . .

obtain efficient administration of a complicated program that depends for its success on the willing and enthusiastic cooperation of four or five different agencies and different professions and disciplines. The center's board members, the director, the teachers, the welfare department counselor, the physician, and the nurse, as well as the educational consultant of the department of welfare who provides overall supervision for the day care centers, all of these contribute to agreement about the purposes and details of the program for the benefit of the child. The director of the center is the key person in the success of the enterprise. Unless the director is keenly interested, we feel the program should not be started in that center.

Cooperation has been achieved consistently, we believe, because of a number of factors. For one, all concerned feel they have shared in its development, and those who have worked with it are thoroughly sold by the experience. Each center has requested it, and the center physician has expressed a definite desire to join the team. Finally, success in many centers has given impetus to others.

Another difficulty is obtaining and keeping qualified physicians and nurses. Physicians need not be pediatric board members, but they must have had experience with children. They must like children and be interested in the whole child, his psychological as well as his physical development, and his family. They must also be interested in the basic type of public health

education represented by the counseling of parents and teachers.

Because of time limitations, providing adequate supervision for the physicians, nurses, and directors has been still another troublesome area. The consulting pediatrician and nurse in the health department plan to visit together an examining session in every center each 6 months.

At least once a year the pediatric and nursing consultants meet with all the center directors, in groups, to try to help them with problems. Twice a year the health department consultants meet with all the physicians in the program for the same purpose. At these latter meetings also some particular phase of the health program is discussed by a specialist, as a means of constantly improving and expanding the program.

Case Histories

To illustrate the value of the health program, two case reports are cited.

L.C., a 5-year-old girl, was generally well but she often needed cathartics because of persistent constipation. She had intermittent enuresis, and there was a unilateral strabismus. Though a reasonably contented child she was high strung and did not always enjoy good relations with the other children in her class. Her mother was so unstable emotionally that she finally was placed in an institution. For this reason a detailed medical history was difficult to obtain.

The child was given glasses for her strabismus

and received some help regarding her constipation and enuresis. The first few health examinations failed to show any other physical abnormalities. Then quite unexpectedly the physician found an elongated mass in the abdomen extending into the pelvis. The child was admitted at once to a hospital where the diagnosis of megacolon was made. A two-stage abdominoperineal rectosigmoid pull-through operation was successfully performed.

The constipation was cured; the enuresis disappeared; and what was particularly noticeable was the change in her disposition. She became happy, made friends easily, and no longer presented the psychological problem she had shown before.

Repeated thorough health examinations discovered a major abnormality which an unsatisfactory history had helped obscure. Prompt referral and skillful surgery quite changed this child's life.

S.B., born January 19, 1951, was admitted to a child care center on June 20, 1955. His mother had not been able to manage him. He had run away from home a number of times. He was restless and destructive. At the child care center, he took no interest in the class activities, destroyed equipment, knocked down houses other children had built, and even molested the children. He never ran away from the center, however, and seemed fond of his teachers. His mother was so disgusted with him that she sent him to the center each morning in an unkempt condition, and efforts to get her to do a better cleanup job were only partly successful. Then the center physician spoke to the child about cleanliness. As a result the child made his mother wash him and give him clean clothes before he would go to the center.

The first few health examinations failed to show any special abnormalities. Vision screening tests proved impossible because the child would not cooperate. However, the physician felt further efforts should be made to test the

child's vision. He was examined at the Kings County Hospital eye clinic where he was found to be suffering from amblyopia.

Glasses were prescribed with the most remarkable results. He obviously saw clearly for the first time. He became interested in class games, used large and small playthings with great interest, participated well with the other children, and was happy and agreeable.

Though he had not given evidence either to his mother or the center staff of poor vision, he obviously saw very little. Being a high strung child, he took his frustrations out on his environment and his associates. A thorough health program discovered his difficulty.

Conclusion

Looking back on our experience, we believe the following factors have been significant. The program is thorough, yet practical. For the most part, the caliber of the center staffs, the consultants both from the department of welfare and from the department of health, and the physicians and nurses has been unusually high. And perhaps most important, every member of the health team has been carefully chosen and repeatedly briefed about the program before it has been started in any center. Provision has been made also to give the physicians preservice and inservice training.

As a result, nearly 5,000 children of low-income families have undoubtedly been given a better quality of health supervision than they would have received otherwise. We believe the parents have gained a better understanding of parent-child relationships and the kind of health care and supervision they should obtain in the future for their children.

We are greatly encouraged by the success of this program in New York City, and we hope that, with whatever modifications are necessary to meet local conditions, it will be given a trial in other cities.

Patterns of Hospital Prepayment Coverage in the United States, 1956

MAURICE E. ODOROFF, M.A., and LESLIE MORGAN ABBE, B.S.

A NATIONAL household survey of the use of general hospitals has afforded an unusual opportunity to obtain firsthand information on the extent of hospital prepayment coverage. The survey covered about 27,000 households, consisting of some 90,000 persons of all ages, drawn from the civilian noninstitutional population of each State then in the Union. It was conducted by the Bureau of the Census in September 1956, in connection with its Current Population Survey, for the Division of Hospital and Medical Facilities of the Public Health Service. It included three-fourths of the families in each of the 330 sample areas comprising the Current Population Survey base (1). Three earlier reports have described the survey procedures and presented provisional findings on various factors associated with the use of general hospitals (2-4).

As a supplement to the main objective of obtaining information on hospital use, three questions were asked in the survey interview about hospital insurance and membership in other plans providing protection against the costs of hospital care. These questions determined whether or not persons had such protection, the principal type of plan held, and the services covered by the plan. This information could be matched with other data collected on personal and family characteristics. To facilitate accuracy on the part of the respondents, each family was sent a letter ex-

plaining the nature and purpose of the survey and asking them to prepare in advance to supply information about hospitalization insurance or other prepayment coverage.

Instructions to the enumerators contained several definitions relating to prepayment coverage. The insurance or prepayment plans to be included were those of a general nature covering all or some part of hospital costs regardless of the reason for entering the hospital. They included the following:

1. Commercial hospital insurance (when not limited to accidents), on either an individual or group basis.
2. Blue Cross or Blue Shield plans, or other nonprofit plans sponsored by medical societies, on either an individual or group basis.
3. Consumer-sponsored plans (not types 1 and 2) which provide prepaid hospital care, including cooperatives and plans sponsored by fraternal organizations.
4. Industrial plans of an employer or union which provide hospital care beyond that legally required for industrial accidents.
5. Other free or reduced-cost hospital plans, such as hospital employee benefits, free hospital care for dependents of Armed Forces members, and the like.

The following policies and plans were excluded since they are for particular purposes or of uncertain availability: (a) policies covering only accidents, "dread diseases," income lost from disability, clinic or office visits, or liability for injury to others, and (b) free hospital care for veterans in Veterans Administration hospitals.

After establishing the existence of prepay-

Mr. Odoroff is chief and Mr. Abbe is assistant chief of the Program Evaluation and Reports Branch, Division of Hospital and Medical Facilities, Public Health Service.

ment coverage in a household, the enumerator asked: "What kind of insurance or plan is it—Blue Cross or something else?" In designating the type of prepayment plan, the term "Blue Cross" is used to include the prepayment plans of more than 80 nonprofit corporate organizations for hospital care, together with related plans of a similar nature covering surgical care under the general term "Blue Shield." "Other plans" are all those not identified as Blue Cross or Blue Shield. For persons who had Blue Cross and another prepayment plan, the enumerators identified and reported only the most comprehensive one. Hence, no more than one plan is reported for each person in the study.

The enumerator next asked: "What kinds of services does the plan cover?" Since all persons previously identified as covered by a prepayment plan were understood to be eligible for hospital care, this question was intended to find out for what other services, if any, they were eligible. The categories of services were defined as follows:

Hospital care: The cost of room and board at the hospital, nursing care, and use of the laboratory, operating room, and similar facilities, whether or not the prepayment plan covers the full cost of all these services.

Surgery: All fees (or any part of the fees) charged by surgeons for performing operations.

Other services: Includes general care by a doctor in a hospital, all hospital costs beyond a certain amount (major medical expense insurance), and similar services other than hospital care as described above. This category may include combinations of services in a hospital other than hospital care and surgery or other single services.

This report presents national data on the percentage of the civilian population with hospital prepayment coverage, in accordance with the definitions described above. The data on the extent of coverage are shown in the accompanying tables with respect to demographic, so-

cial, and economic characteristics of the people covered. Coverage is classified by race and sex, age and sex, veteran status, urban-rural type of residence, employment status, and income status for families and individuals. Highlights of the findings are discussed below.

Demographic Factors

Race and sex. Very little difference appears in the extent of prepayment protection for men and that for women, either in the total coverage or in the various forms (table 1). The nonwhite population, however, has much less coverage than the white population. Of the white population, 52.1 percent have hospital and surgical prepayment protection, but only 25.2 percent of the nonwhite population are covered. Coverage under all plans stands at 67.0 percent for the white population and at 35.7 percent for the nonwhite.

Age. The proportion of the population with hospital prepayment protection varies considerably with age (table 2). Coverage under all plans for children under 14 years old is reported as 64.1 percent. The rate rises to a maximum of about 71 percent for persons 25 to 44 years of age, then decreases moderately to age 64. For persons 65 and over, prepayment coverage under all plans combined falls to 36.5 percent, coverage for men of this age reaching 39.2 percent and for women dropping to 34.2 percent.

Table 3. Hospital prepayment coverage status for males 14 years and over by veteran status, September 1956

² Urbanized areas comprise a central city of 50,000 population with its urban fringe, defined as contiguous areas of a population density of 500 dwelling units per square mile, plus similar nonecontiguous areas within 1½ miles highway distance. (Metropolitan areas include entire counties and are usually considerably larger than their urbanized areas.) U.S. Bureau of the Census: Census of Population: 1950, vol. 1, pp. xxvii and xxxv.

Veteran status. Only minor variation exists with respect to veteran status for total prepayment coverage (table 3). The rate for all veterans is 70.6 percent and for nonveterans, 60.3 percent. The younger veterans of World War II have a slightly higher percentage of coverage.

Social Factors

Type of residence. The rate of coverage for hospital prepayment protection is consistently high for persons in cities of 50,000 inhabitants or more (table 4). These cities and their built-up fringe areas, defined by the Bureau of the Census as "urbanized areas," have a coverage rate of 69.2 percent. The level of prepayment protection is slightly less for people residing in cities with populations between 2,500 and 25,000, where 64.0 percent are covered. Coverage is much less, 40.3 percent, for people who live on farms.

Employment status and industry. Very marked differentials appear in the proportion

ment coverage in a household, the enumerator asked: "What kind of insurance or plan is it—Blue Cross or something else?" In designating the type of prepayment plan, the term "Blue Cross" is used to include the prepayment plans of more than 80 nonprofit corporate organizations for hospital care, together with related plans of a similar nature covering surgical care under the general term "Blue Shield." "Other plans" are all those not identified as Blue Cross or Blue Shield. For persons who had Blue Cross and another prepayment plan, the enumerators identified and reported only the most comprehensive one. Hence, no more than one plan is reported for each person in the study.

The enumerator next asked: "What kinds of services does the plan cover?" Since all persons previously identified as covered by a prepayment plan were understood to be eligible for hospital care, this question was intended to find out for what other services, if any, they were eligible. The categories of services were defined as follows:

Hospital care: The cost of room and board at the hospital, nursing care, and use of the laboratory, operating room, and similar facilities, whether or not the prepayment plan covers the full cost of all these services.

Surgery: All fees (or any part of the fees) charged by surgeons for performing operations.

¹ Primary family members include persons related by blood, marriage, or adoption (one being the head of the household); primary individuals are heads of households not living with relatives. "Income" for members of primary families includes money income of all members of the family; for primary individuals, it includes personal income only.

² See table 1, footnote 1.

other sources of coverage (table 7). However, the proportion of all coverage carried by Blue Cross-Blue Shield is about 40 percent for persons with family incomes of less than \$1,000, and about 60 percent at incomes of \$10,000 or more.

Comparison With Other Studies

The data obtained from this study in 1956 provide a useful benchmark in the field of prepayment coverage, which is one of the most rapidly changing aspects of medical care today. One other study on a national scale was conducted in 1953 by Anderson and Feldman, for the Health Information Foundation (5). In addition, annual estimates on the number

of people protected for hospital, surgical, and regular medical expense have been compiled since 1940 by the Health Insurance Council, which now comprises eight insurance associations. These estimates afford a panorama not elsewhere available as to historical trends in the health insurance field (6).

A fairly close correlation appears between

¹ See table 6, footnote 1.

of hospital prepayment protection according to employment status (table 5). Among wage and salary workers in agriculture the coverage rate is 26.5 percent, much less than one-half the rate of 68.1 percent for all persons in the labor force. At the other end of the scale, wage and salary workers in manufacturing have prepayment protection for 84.9 percent of their number. The lowest coverage among employed persons outside agriculture is in domestic service, with 44.6 percent covered. Among disabled persons, who cannot work, the coverage is about 21 percent.

Income and Family Status

Income is more closely associated with the extent of prepayment protection than any other factor investigated. For both primary families and primary individuals, prepayment pro-

tection rises rapidly as income increases (table 6). When family income is less than \$1,000, only 18.4 percent of primary family members have coverage of any kind. This figure may be compared with 65.2 percent for all primary families and a maximum of 83.6 percent for families with incomes between \$7,500 and \$10,000. A slightly lower proportion of families with incomes over \$10,000, 80.1 percent, have prepayment coverage. For all primary individuals (who live alone or else maintain a household with persons not related to them) the level of prepayment coverage is 47.5 percent, or less than three-fourths of the coverage for all members of primary families.

Income is also related to the type of protection plan carried. Prepayment coverage increases steadily with income, both under Blue Cross plans (including Blue Shield) and under

⁷ \$2,000-\$3,500.

⁸ \$3,500-\$4,999.

The most important contrasts in the extent of prepayment protection are associated with variation in income. In primary families with incomes of less than \$1,000 only 18 percent of the members had protection of any kind. The highest coverage rate was 83.6 percent in families with incomes between \$7,500 and \$10,000. Differences in the rate of prepayment coverage were also great with respect to type of employment: wage and salary workers in agriculture had only 26.5 percent coverage, while those in manufacturing had 84.9 percent. Age, too, was related notably to extent of coverage. Persons 65 years or over had a coverage rate of 36.5 percent, while maximum coverage amounted to 71.5 percent at ages 35 to 44 years. People living on farms had a total coverage of only 40.3 percent. Persons with low incomes had a lower proportion of their total coverage under Blue Cross and Blue Shield than did persons of above-average incomes.

These patterns of hospital prepayment coverage in 1956 provide a benchmark in a rapidly changing field. They also underscore those aspects of our social fabric in which health care is uncertain.

the trend estimates and the data of the 1953 and 1956 surveys, as shown in the accompanying chart. In this chart all data are related to the total civilian population. Adjustments from a population base covering only the non-institutional population were considered advisable for the data of the two surveys in the comparison because of the difficulty in projecting annual change in institutional population for trend purposes. On this basis, the 1953 survey shows a level of prepayment coverage 6.4 percent below the interpolated percentage estimate of the Health Insurance Council. The 1956 survey shows a level 7.8 percent below the interpolated estimate of the Health Insurance Council. The close agreement of these differentials in the 1953 study and in the present report, when a substantially larger sample base was used (about 90,000 persons, as compared with 8,846 persons), suggests the possibility of overstatement in the annual trend series. One recognized difficulty in the Health Insurance Council estimates is an exact adjustment for duplicate coverage. This was noted in the report of the 1953 survey (5). Other possible sources of differences noted therein include some lag in processing lapsed policies and the likelihood of some under-reporting of coverage by survey response, such as the failure to men-

tion disability policies which carry minor payments for hospital charges.

Another survey on a small scale in Ohio, Connecticut, and Vermont in 1953-54 found that 69 percent of the 1,657 persons studied had hospital prepayment coverage, but this level appears to be sectional in nature (7).

Some comparisons can be made between the Health Information Foundation survey of 1953 and the Public Health Service survey of 1956 with respect to coverage according to socioeconomic characteristics. Table 8 sets forth direct results of the two surveys, based on the noninstitutional civilian population.

Between 1953 and 1956 coverage increased 11 percent nationally, but in rural nonfarm areas it increased 24 percent. Rural nonfarm areas include communities below 2,500 in population and the nonurban fringes of large cities, where it may be assumed that rapid growth in population is principally of urban-oriented families.

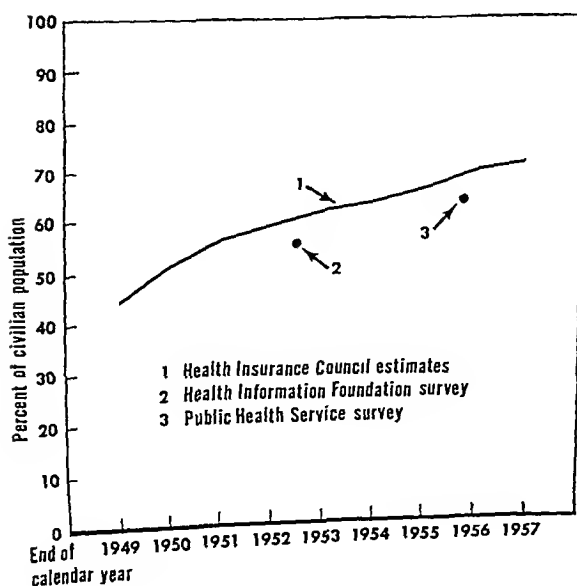

Persons aged 65 years or over with prepayment coverage have increased from 31 percent in 1953 to 36.5 percent in 1956, a proportional gain of 18 percent. A more extensive analysis of the original data of the 1956 survey relating to persons 65 and over has been carried out through special tabulations developed for the Social Security Administration (8).

Levels of prepayment coverage for selected industries in the two studies are shown in table 8 because of their general similarity, although in some cases the reporting bases are different. Distribution of coverage by family income groups also shows fairly close similarity, although income groups were not identical.

Summary

The type and extent of prepayment protection against the costs of hospital care were studied in a national household survey in 1956. A sample of about 27,000 families with 90,000 persons of all ages was interviewed, with sample areas in every State. Hospital prepayment coverage was carried by 63.6 percent of the noninstitutional civilian population. This may be compared with a level of 57 percent found by a Health Information Foundation study in 1953. Hospital and surgical expenses were covered in 1956 for 49.2 percent of the population; hospital expenses only, for 8.4 per-

Hospital prepayment coverage, United States, 1949-57

A study of some 200,000 life insurance policyholders contributes striking evidence that regular cigarette smokers are subject to increased risk of dying from lung cancer, as well as cardiovascular disease, certain respiratory diseases, ulcers, and cirrhosis of the liver.

Tobacco Consumption and Mortality From Cancer and Other Diseases

HAROLD F. DORN, Ph.D.

IN 1954 the Public Health Service in cooperation with the Veterans Administration initiated a study of the causes of death among policyholders of U.S. Government life insurance. This insurance was available only to persons who served in the Armed Forces of the United States between 1917 and 1940. Although most of the policyholders were veterans of World War I, an appreciable number first served after that date. All except less than 0.5 percent of the policyholders included in this study were men.

Method of Study

Beginning in January 1954, a questionnaire requesting information concerning the use of tobacco, usual occupation, and industry was mailed to each policyholder. Usable replies were received from 198,926 persons, or 68 percent of those included in the original mailing. A second questionnaire was mailed to nonrespondents beginning in January 1957. Usable replies were received from an additional 50,000 policyholders, making a total of approximately 249,000, or 85 percent of the number included in the study, for whom information concerning the use of tobacco, occupation,

and residence is available. The nonrespondents have been retained in the study, and the same medical information is available for them as for the respondents.

Whenever a claim is filed for the payment of a policy, the Veterans Administration forwards a copy of the death notice, usually a copy of the official death certificate, to the Public Health Service. Additional medical information, including verification of the causes of death

Dr. Dorn is chief of the Biometrics Branch, Division of Research Services, National Institutes of Health, Public Health Service. This paper is an expanded version of one he presented before the Seventh International Cancer Congress in London, July 8, 1958, which will be published in the Acta, Unio Internationalis Contra Cancrum, during 1959.

The study was carried out in cooperation with the Field Investigations and Demonstrations Branch, National Cancer Institute, Dr. R. F. Kaiser, chief. Dr. W. S. Baum, Division of Indian Health, Public Health Service, assisted in planning and initiating the study.

The Veterans Administration, whose cooperation made the study possible, is nevertheless not responsible for, nor does it necessarily endorse, any of the findings or conclusions of this report.

A study of some 200,000 life insurance policyholders contributes striking evidence that regular cigarette smokers are subject to increased risk of dying from lung cancer, as well as cardiovascular disease, certain respiratory diseases, ulcers, and cirrhosis of the liver.

Tobacco Consumption and Mortality From Cancer and Other Diseases

HAROLD F. DORN, Ph.D.

IN 1954 the Public Health Service in cooperation with the Veterans Administration initiated a study of the causes of death among policyholders of U.S. Government life insurance. This insurance was available only to persons who served in the Armed Forces of the United States between 1917 and 1940. Although most of the policyholders were veterans of World War I, an appreciable number first served after that date. All except less than 0.5 percent of the policyholders included in this study were men.

Method of Study

Beginning in January 1954, a questionnaire requesting information concerning the use of tobacco, usual occupation, and industry was mailed to each policyholder. Usable replies were received from 198,926 persons, or 68 percent of those included in the original mailing. A second questionnaire was mailed to nonrespondents beginning in January 1957. Usable replies were received from an additional 50,000 policyholders, making a total of approximately 249,000, or 85 percent of the number included in the study, for whom information concerning the use of tobacco, occupation,

and residence is available. The nonrespondents have been retained in the study, and the same medical information is available for them as for the respondents.

Whenever a claim is filed for the payment of a policy, the Veterans Administration forwards a copy of the death notice, usually a copy of the official death certificate, to the Public Health Service. Additional medical information, including verification of the causes of death

Dr. Dorn is chief of the Biometrics Branch, Division of Research Services, National Institutes of Health, Public Health Service. This paper is an expanded version of one he presented before the Seventh International Cancer Congress in London, July 8, 1958, which will be published in the Acta, Unio Internationalis Contra Cancrum, during 1959.

The study was carried out in cooperation with the Field Investigations and Demonstrations Branch, National Cancer Institute, Dr. R. F. Kaiser, chief. Dr. W. S. Baum, Division of Indian Health, Public Health Service, assisted in planning and initiating the study.

The Veterans Administration, whose cooperation made the study possible, is nevertheless not responsible for, nor does it necessarily endorse, any of the findings or conclusions of this report.

SMOKING HISTORY

Persons were classified by smoking history in accordance with the following definitions.

Used tobacco: Persons who had smoked at least 5 to 10 packs of cigarettes or 50 to 75 cigars or 3 to 5 packages of pipe tobacco.

Smoked occasionally only: Persons who had never regularly smoked any form of tobacco but who had occasionally smoked one or more forms. Also included here were persons with unknown amount used either currently or in the past, provided that the maximum amount of known use was occasional only.

Regular smoker: Persons who at sometime during their lifetime had regularly smoked cigars, cigarettes, or pipe tobacco. These were further classified by the form of tobacco used and whether or not they were smoking at the start of the study in 1954.

Regular smoker, cigarettes only: Persons who had regularly smoked only cigarettes. They may have occasionally smoked cigars or a pipe, but they had never smoked either of these regularly.

Regular smoker, cigarette and cigar: Persons who had regularly smoked both cigarettes and cigars. They may have smoked a pipe occasionally but never regularly. Similar definitions were used for regular smokers of other combinations of tobacco.

Amount unknown: Persons who stated they had smoked more than the minimum amount to qualify as a user of tobacco but who did not report the amount used either currently or in the past with sufficient accuracy to permit assignment to one of the groups of regular or occasional smokers.

Amount used: In this report, classification by amount of tobacco used is based on the current amount used at the time the questionnaire was filled

out in 1954. Regular smokers of (a) cigarettes and cigars, (b) cigarettes and pipe, and (c) cigarettes, cigars, and pipe were classified by the current number of cigarettes smoked. Regular users of cigars and pipes were classified by the current number of cigars smoked.

CAUSE OF DEATH

The broad groups of causes of death used in this study (table 4 and fig. 5) include the following categories of the International Statistical Classification of Diseases, Injuries, and Causes of Death (seventh revision, 1955):

Cancer of lung: 162, 163.

Cancer except lung: 140-205, except 162, 163.

Respiratory diseases:

Respiratory tuberculosis: 001-008.

Asthma: 241.

Influenza and pneumonia: 480-493.

Bronchitis: 500-502.

Emphysema without bronchitis: 527.1.

Other respiratory diseases: 470-475; 527.0; 527.2; 510-526.

Accidents:

Motor vehicle accidents: 810-835.

Other accidents: 800-802; 840-962; 980-991.

Suicide: 970-979.

Cardiovascular diseases:

Cerebral vascular lesions: 330-334.

Rheumatic fever: 400-402.

Chronic rheumatic heart disease: 410-416.

Arteriosclerotic heart disease: 420.

Nonrheumatic chronic endocarditis: 421-422.

Other heart disease: 430-434.

Hypertension with mention of heart disease: 440-443.

Hypertension without mention of heart disease: 444-447.

General arteriosclerosis: 450.

Other circulatory system disease: 451-468.

Chronic nephritis: 592-594.

Other diseases: Remaining categories.

entered on the death certificate, the procedures used to establish these diagnoses, whether the deceased had cancer even though it was not considered to be an underlying or contributory cause of death, and the histological type of cancer, is requested from the physician who signed the death certificate or from the hospital where the death occurred.

Verification of the cause of death is not re-

quested whenever the death occurs outside the United States, is due to an accident, or is certified by a coroner. Replies have been received to more than 99 percent of the letters of inquiry.

The underlying cause of death was changed for 6 percent of the deaths for which a comparison could be made between the entry on the official death certificate and the subsequent in-

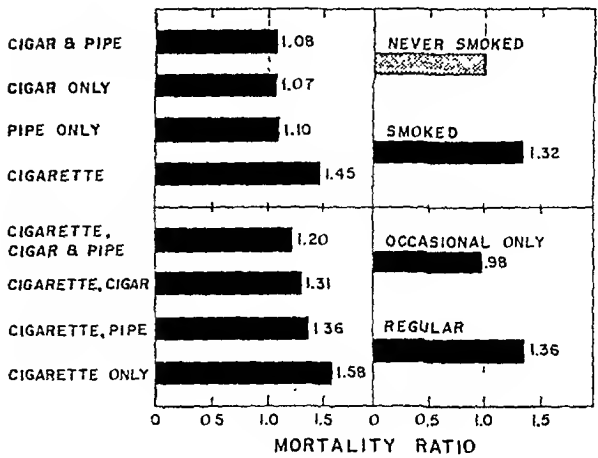

formation received in response to the letters of inquiry. Additional diseases contributory to death were reported for another 12 percent of the deaths, although the underlying cause was unchanged.

An autopsy had been made in nearly one-third (31 percent) of the deaths for which information concerning method of diagnosis was obtained. For about one-half of the deaths (47 percent) the diagnoses were established by exploratory surgery, endoscopy, radiography, or various laboratory tests. The diagnoses of the remaining one-fifth (22 percent) of the deaths were based upon physical examination and clinical history.

Basis of This Report

This report is based on deaths occurring during the 2½-year period July 1954–December 1956 among persons for whom information concerning use of tobacco was obtained prior to July 1954. Deaths during the first 6 months of 1954 have been excluded since the original questionnaire about the use of tobacco was mailed during this period. In addition to persons who died before they received a questionnaire, replies were not received from some persons who were seriously ill when the questionnaire was received; any deaths among these persons were

Figure 1. Mortality of smokers and nonsmokers; ratio of observed to expected number of deaths.

assigned to the group of nonrespondents. Although the death rate of the entire group of policyholders was not changed by this exclusion, the rates for both the nonrespondents and the respondents were biased since a disproportionate number of deaths had to be assigned to the nonrespondent group. Inspection of the data revealed that the effect of this bias had largely disappeared by July 1954.

The following data are based on 478,952 person-years exposure, of which 89,774 were contributed by persons who had never smoked

Table 1. Mortality of smokers and nonsmokers: Ratio of observed to expected number of deaths (all causes), by smoking history and current use, July 1954–December 1956

Smoking history	Number of person-years exposure	Current use		
		Total	Smokes	Does not smoke
Never smoked	89,774	1.00		
Used tobacco	389,178	1.32	1.37	1.24
Occasionally only	28,144	.98	.91	1.05
Regular smoker	339,903	1.36	1.40	1.30
Cigarette total	271,757	1.45	1.54	1.30
Cigarette only	161,172	1.58	1.65	1.39
Cigarette and other	110,585	1.29	1.35	1.21
Cigarette and cigar	21,188	1.31	1.34	1.27
Cigarette and pipe	53,168	1.36	1.41	1.26
Cigarette, cigar, pipe	36,229	1.20	1.28	1.11
Cigar only	28,422	1.07	.94	1.44
Cigar and pipe	21,944	1.08	1.04	1.21
Pipe only	17,780	1.10	1.05	1.25
Amount unknown	21,131	1.06	1.43	1.05

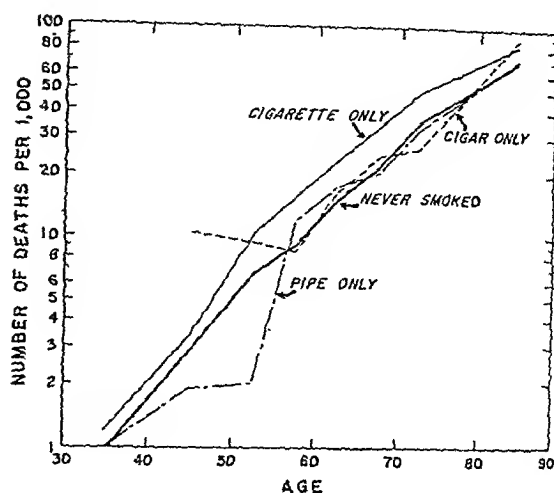

NOTE: Expected number of deaths computed by multiplying the number of person-years exposure in each age group for each smoking history category by the age-specific death rates of persons who had never smoked.

and 389,178 by persons who had smoked tobacco in some form during their lifetime. The number of person-years exposure of persons classified by type of smoking history is shown in table 1.

Unless otherwise specified, the death rate for smokers is expressed as a ratio to that for persons who have never smoked. This mortality ratio is calculated by dividing the number of observed deaths for each smoking history group by the number of expected deaths based on the age-specific death rates of persons who have never smoked. The ratio of 1.32 shown in table 1 for persons who have smoked tobacco at some time means that the death rate for these persons from all causes combined is 32 percent greater than the rate for persons who have never smoked.

The mortality ratio as used here is a measure of the relative excess mortality of smokers compared with nonsmokers. An equally valid measure would be the absolute difference between the observed and the expected number of deaths. The total number of excess deaths, if any, may be apportioned among the various individual causes of death, thus ranking the causes according to the proportion of the total excess number of deaths for which they are responsible. These two measures are designed to emphasize different aspects of the variation in mortality between two groups. The main interest in this paper is the relative difference

Figure 2. Death rate of regular smokers and nonsmokers by age and type of tobacco used.

in the death rate of smokers and nonsmokers; therefore, the mortality ratio will be used exclusively.

Mortality by Type of Smoking

The largest increase in mortality among persons who have smoked is found for those who have regularly smoked only cigarettes (fig. 1). The death rate for these smokers is 58 percent greater than that for nonsmokers. Persons who have smoked regularly only cigars, only a pipe, or cigars and a pipe die at a rate

Table 2. Mortality by age among smokers and nonsmokers: Number of deaths per 1,000 per year, by smoking history and age, July 1954–December 1956

Smoking history	Number of deaths	Death rate per 1,000								
		All ages	30-39	40-49	50-54	55-59	60-64	65-69	70-74	75 and over
Never smoked	1,179	13.1	0.7	2.9	6.6	9.0	14.8	21.6	35.8	70.0
Used tobacco	6,203	15.9	1.3	3.2	9.3	13.1	19.0	28.1	38.6	73.3
Occasionally only	345	12.3	2.0	2.7	3.2	9.5	12.9	23.6	30.6	85.2
Regular smoker	5,564	16.4	1.3	3.4	9.8	13.6	19.8	28.9	39.6	72.6
Cigarette total	4,513	16.6	1.4	3.3	10.4	14.4	20.9	31.2	43.5	72.8
Cigarette only	2,771	17.2	1.2	3.4	10.4	15.3	22.9	33.4	49.8	84.7

NOTE: Expected number of deaths computed by multiplying the number of person-years exposure in each age group for each smoking history category by the age-specific death rates of persons who had never smoked.

only slightly in excess of that for nonsmokers. Individuals with a history of regularly smoking cigars or a pipe, or both, in addition to cigarettes are subject to a mortality rate definitely greater than that for nonsmokers but less than the rate for persons who have smoked regularly only cigarettes. Occasional smoking, irrespective of the form of tobacco used, apparently has no effect upon the total death rate.

On January 1, 1954, the policyholders included in this study varied in age from 30 years to more than 80 years. The vast majority, 84 percent, were between 50 and 70 years of age; only 2 percent were more than 70 years old.

The age-specific death rates presented in table 2 and figure 2 show the same relationship between the death rate from all causes and smoking history as the average rates for all ages

combined given in table 1. The relative amount of the excess mortality of regular smokers in comparison with that of nonsmokers decreases after age 70, but this finding cannot be regarded as firmly established because of the small number of persons who were more than 70 years old at the start of the study.

Mortality of Ex-Smokers

Regular cigarette users who had stopped smoking prior to the start of the study in 1954 have a lower death rate than persons who continued to smoke (table 1). Nevertheless their death rate on the average still exceeds that for nonsmokers by 30 percent. The largest absolute decrease in the mortality ratio is found for ex-smokers who have regularly smoked cigarettes only; their mortality ratio is 1.39 com-

pared with 1.65 for persons who were still smoking cigarettes.

The much higher mortality among men who have smoked regularly only cigarettes is emphasized by the fact that the mortality ratio for those who have stopped smoking, 1.39, is slightly greater than the ratio, 1.35, for persons who were continuing to smoke cigarettes in combination with cigars or a pipe. Part of the difference in the death rates for these two groups of cigarette smokers is accounted for by the fact that persons who regularly smoke cigars or a pipe as well as cigarettes smoke fewer cigarettes per day, on the average, than do persons who regularly smoke only cigarettes. After adjusting for differences in age and average number of cigarettes currently smoked, the death rate from all causes combined for cigarette-only smokers is 14 percent greater than

that for persons who smoke cigars or a pipe in addition to cigarettes.

In contrast to cigarette smokers, ex-smokers of cigars and pipes are subject to a higher death rate than persons who continue to smoke these forms of tobacco. The death rate of those who were still regularly smoking cigars or a pipe in early 1954 does not differ significantly from that of persons who had never smoked, whereas the corresponding rate for ex-smokers ranged from 21 to 44 percent higher. This finding suggests that many of these ex-smokers may have stopped smoking because of ill health. Whether or not this ill health may have been related to the use of tobacco is unknown.

Mortality by Current Amount Smoked

Two indexes of the amount of tobacco smoked are available for the persons included in this

Figure 3. Mortality of regular smokers by current amount smoked in 1954 and type of tobacco used; ratio of observed to expected number of deaths.

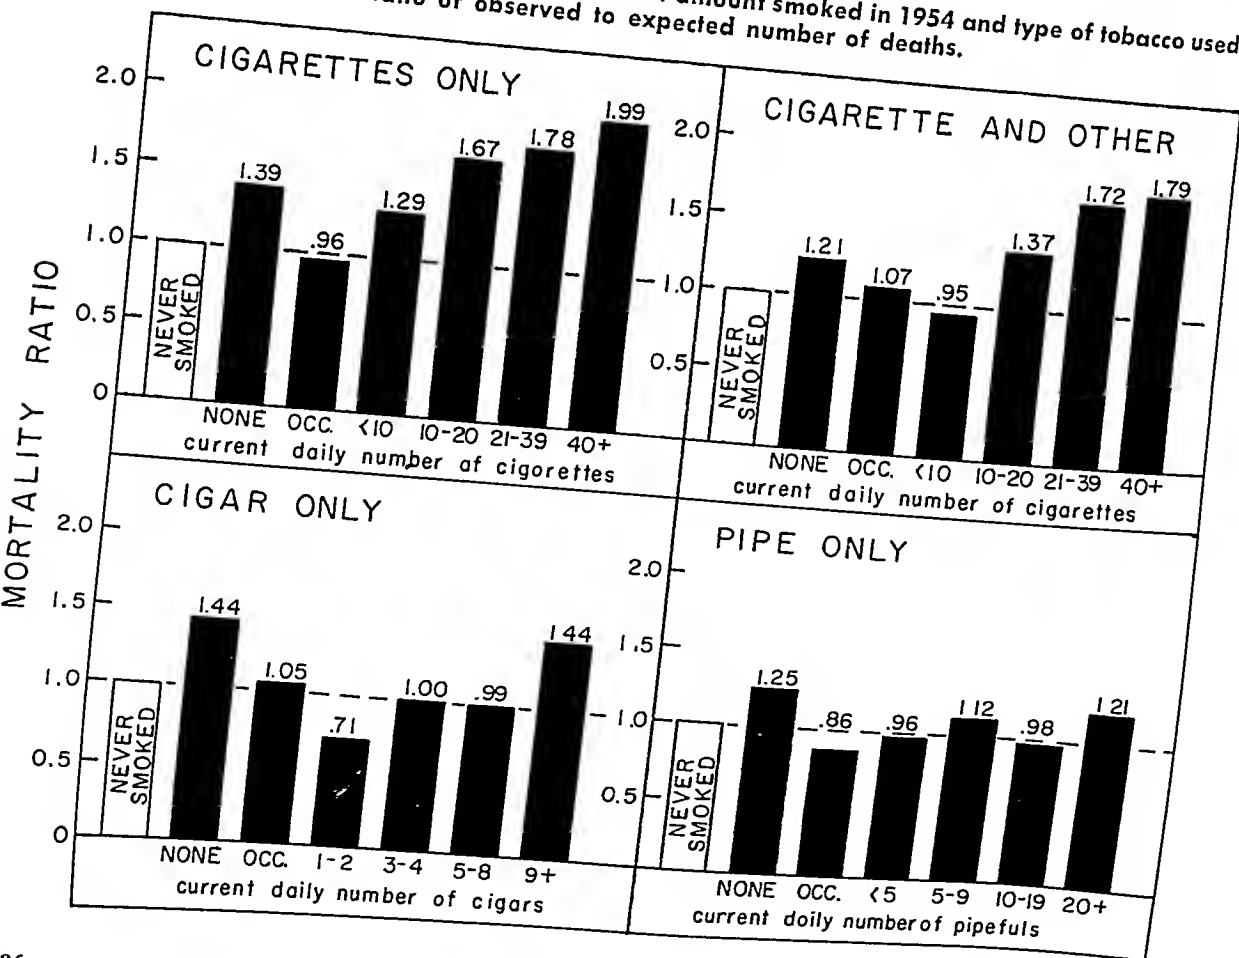

Table 4. Mortality of smokers from broad groups of causes: Ratio of observed to expected number of deaths, by smoking history and causes,¹ July 1954–December 1956.

¹ Underlying causes only.

² Expected number of deaths computed by multiplying the number of person-years exposure in each age group for each smoking history category by the age-specific death rates from each cause of death of persons who had never smoked or who had used tobacco only occasionally.

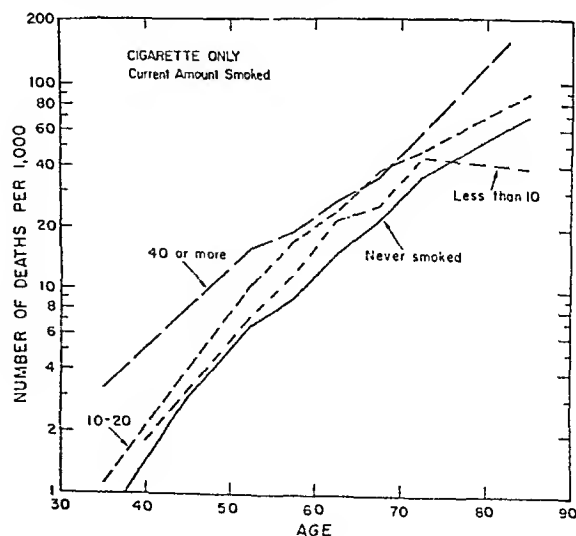

study: (a) the maximum amount ever regularly smoked, and (b) the amount currently smoked in early 1954. Table 3 and figure 3 present mortality ratios for persons currently smoking specified quantities of tobacco in 1954. All of these had smoked regularly at some time, even those smoking only occasionally at the time they completed the questionnaire.

The excess mortality of cigarette smokers is directly related to the average daily number of cigarettes smoked. Those who smoke two packs or more a day have the highest death rate—a rate averaging nearly twice that for nonsmokers. The death rates by age and current amount smoked for regular cigarette users presented in figure 4 show the same direct relationship with the average daily number of cigarettes smoked as do the rates for all ages combined in figure 3.

Only very heavy cigar or pipe smokers experience a higher mortality than nonsmokers. The death rates for the heaviest cigar or pipe smokers, those currently smoking 9 or more cigars or 20 or more pipefuls per day, are about

the same as the rate of persons who smoke from one-half to one pack of cigarettes per day. Among these smokers the mortality ratio is sig-

Figure 4. Death rate of nonsmokers and regular cigarette smokers by age and current amount smoked in 1954.

nificantly greater than one only for persons who regularly smoke cigars only and for the total of the three cigar- and pipe-smoking groups. These data lead to the conclusion that cigar or pipe smoking does not increase the total mortality rate unless large amounts of these forms of tobacco are consumed.

Classification of Deaths

Causes of death were classified according to the rules of the International Statistical Classification of Diseases, Injuries, and Causes of Death published by the World Health Organization. One underlying and a maximum of two contributory causes of death were coded. The selection of the underlying cause of death

was based on the opinion of the deceased's physician except when it was obvious that the physician had misunderstood the intent of the question and had selected a terminal condition such as pulmonary failure or edema as the underlying cause. In addition, a separate code was provided for cases with cancer which the physician stated was not a contributory or underlying cause of death.

The mortality ratios for broad groups of causes (table 4, fig. 5) are based on the underlying cause of death; hence there is only one cause for each death. The mortality ratios for the specific causes of death (figs. 6 and 7, table 5) were computed from both underlying and contributory causes, and for cancer they also in-

Figure 5. Mortality of smokers from broad groups of causes of death; ratio of observed to expected number of deaths; death rate of nonsmokers and persons who have smoked only occasionally equals 1.00.

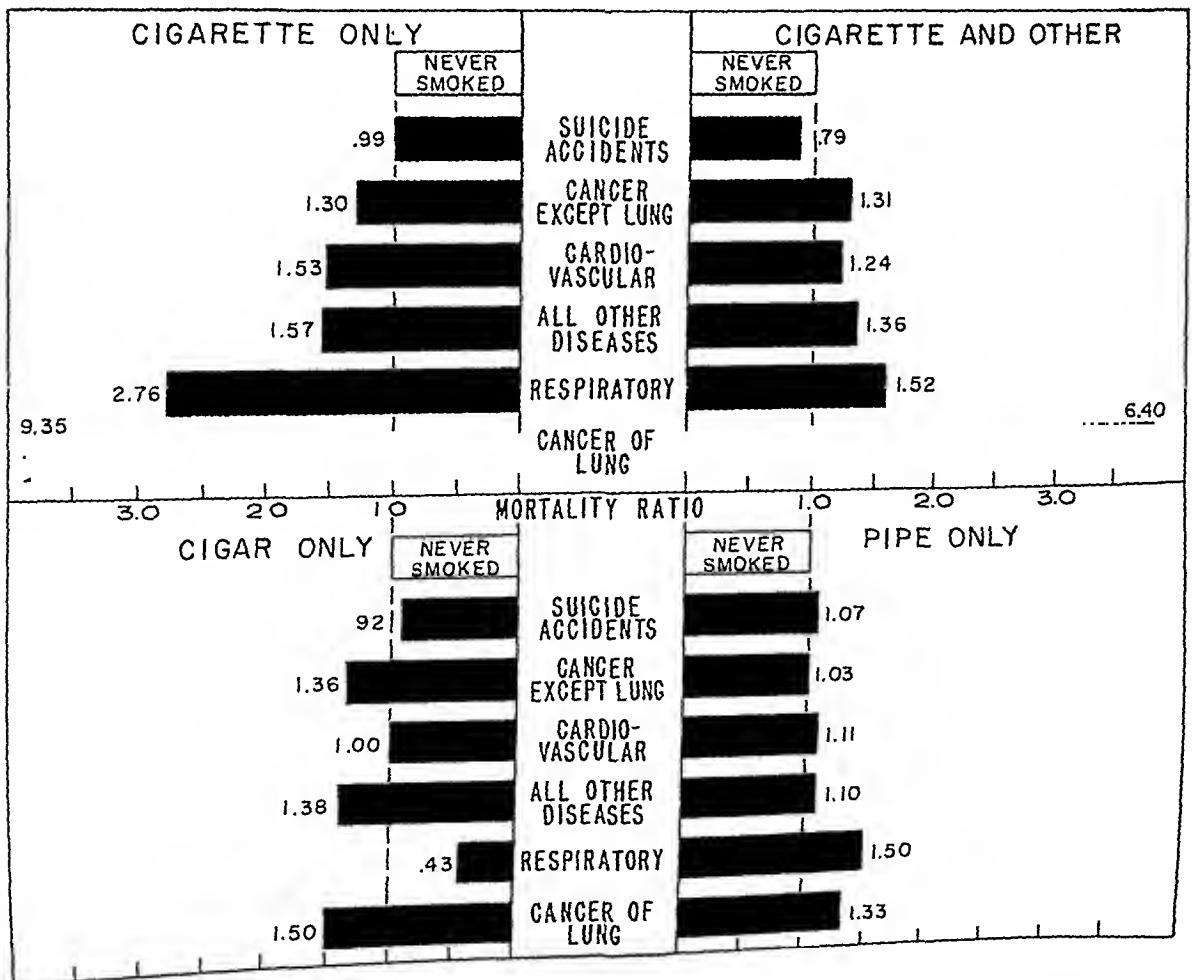

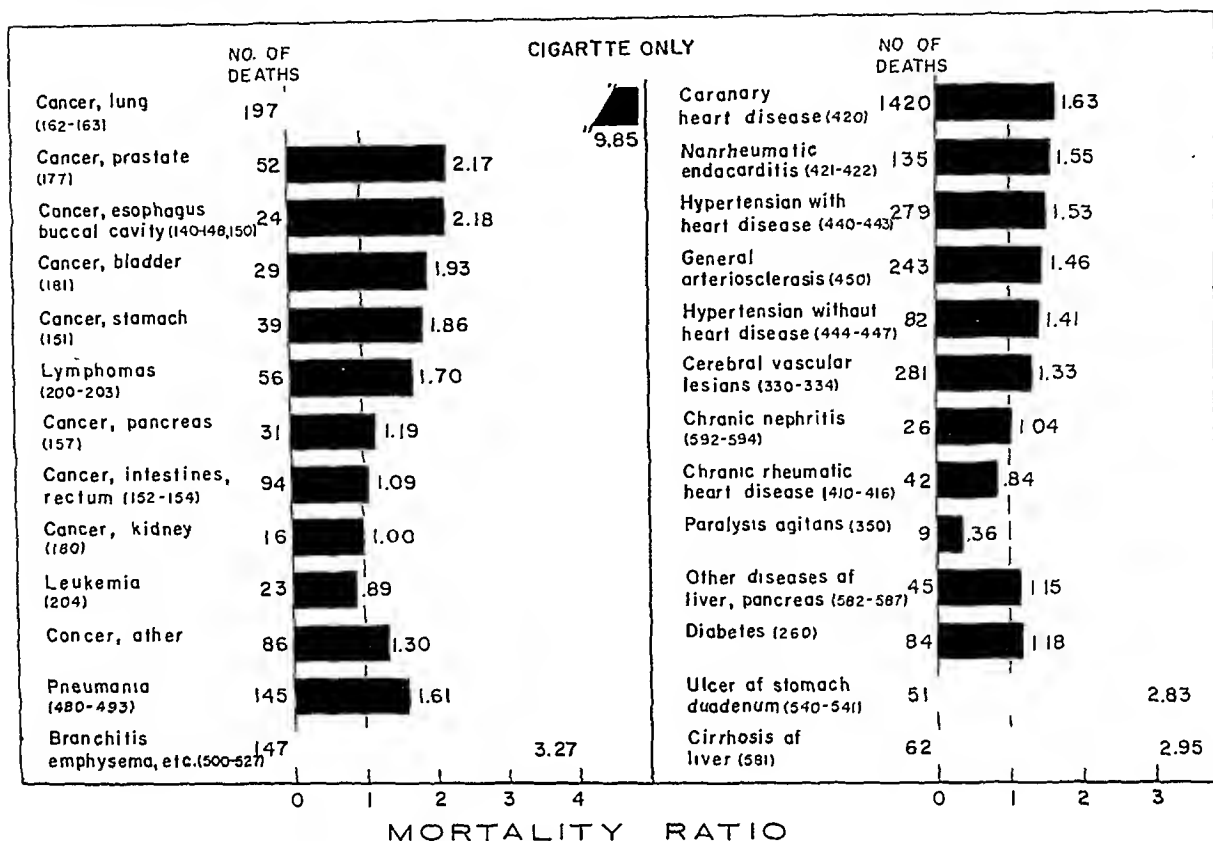

Figure 6. Mortality of regular smokers of cigarettes only from specific diseases; ratio of observed to expected number of deaths; death rate of nonsmokers and persons who have smoked only occasionally equals 1.00.

clude cases with a cancer which the physician stated did not contribute to death. Examples of the latter are skin cancer or clinically quiescent cancer of the prostate discovered during autopsy. One hundred and seventeen of the persons who died had a cancer which was not considered one of the causes of death by the attending physician. Eight of these were cancer of the lung.

The selection of one of several coexisting diseases as the underlying cause of death frequently must be rather arbitrary. In studies of the etiology of disease the important question is whether or not a given disease has developed, not whether this disease has been designated by some method as the underlying cause of death. Hence the data in figure 6 are based on the number of cases of a specified disease. If a policyholder had both diabetes and cancer of the lung, he was counted twice, once in the group with diabetes and once in the

group with cancer of the lung. Consequently, the sum of the numbers of observed deaths is greater than the number of persons who died.

The expected number of deaths on which the mortality ratios by cause are based were computed from the death rates for persons who had never smoked and those who had smoked only occasionally in order to have a statistically more stable basis of comparison. The only cause in table 4 for which the death rates for these two groups differed appreciably is cancer of the lung. There were 10 deaths among persons with lung cancer from the 89,774 person-years exposure of the never-smoked group and 7 deaths from the 28,144 person-years exposure of persons who smoked only occasionally. The corresponding crude death rates were 11 and 25 per 100,000, but this difference is not statistically significant. For simplicity of expression the combined group will be referred to as having never smoked.

Mortality From Broad Cause Groups

By far the greatest increase for smokers in the risk of developing a disease is that for lung cancer. For all persons who had ever smoked the observed number of cases of lung cancer was 312 compared with 52 expected, a mortality ratio of 6.0 (table 4). However, the amount of the increased risk varies widely among the various groups of smokers, ranging from an excess of 33 percent for pipe smokers to 835 percent for cigarette-only smokers. The mortality ratio for none of the three cigar-pipe-smoking groups differs significantly from one; the ratio for the three combined, 1.60, is barely significant at the 5 percent level.

For no other disease does the excess mortality among smokers approach that for lung cancer. The next highest mortality ratio is for a group of respiratory diseases including pulmo-

nary tuberculosis, asthma, bronchitis, emphysema, pneumonia, and pleurisy (fig. 5). Although these diseases are important causes of morbidity, they are numerically unimportant as primary, or underlying, causes of death; only 118 deaths among smokers and 24 deaths among nonsmokers were due directly to one of this group of diseases. The majority of these deaths were attributed to bronchitis, emphysema, pleurisy, empyema, fibrosis of the lung, and similar conditions.

An increased death rate from this group of respiratory diseases is found only among regular cigarette smokers, for whom the mortality ratio is 2.24. As for lung cancer, the highest ratio for respiratory diseases, 2.76, is for persons who smoke cigarettes only. Although the number of deaths among persons who regularly smoke only cigars or a pipe is small, there is

Figure 7. Mortality of regular smokers of cigarettes only, by current amount smoked in 1954 and specific disease; ratio of observed to expected number of deaths; death rate of nonsmokers and persons who have smoked only occasionally equals 1.00.

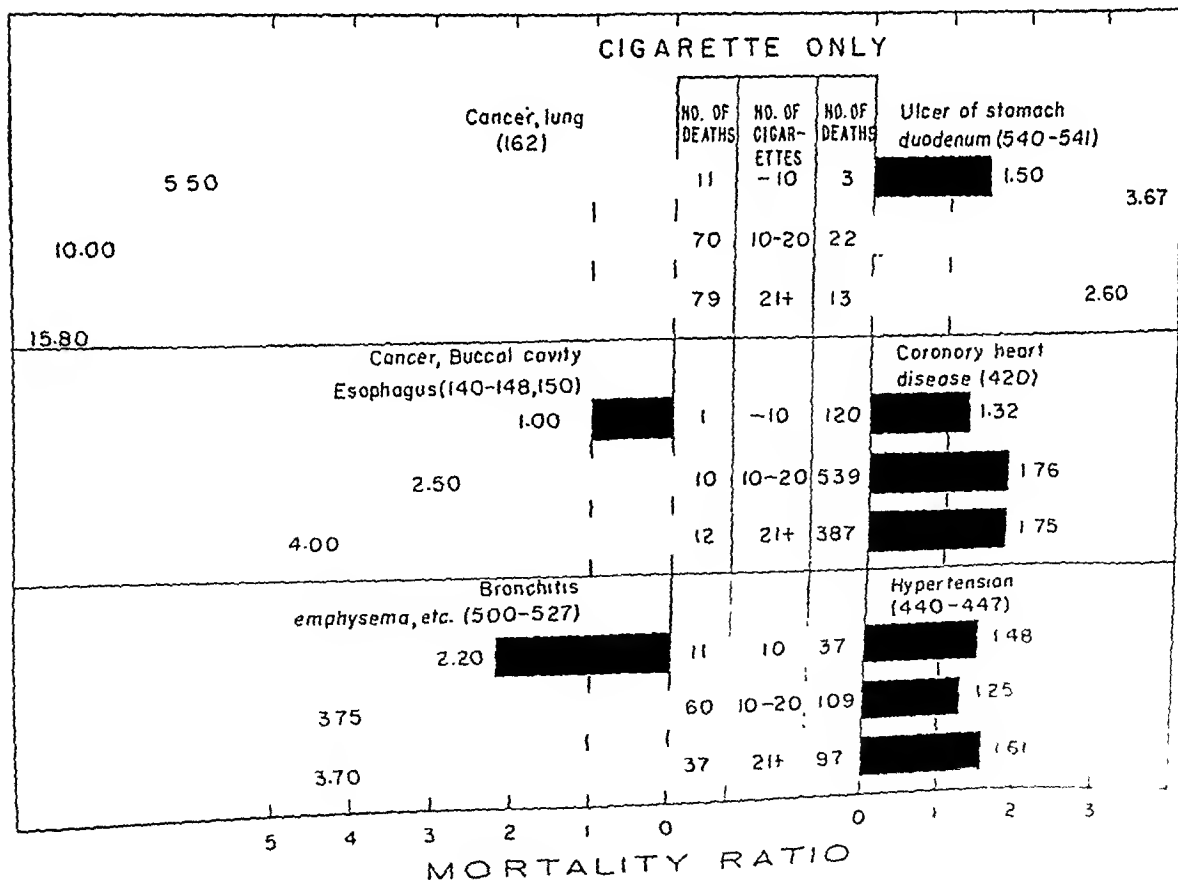

Table 5. Mortality of regular cigarette smokers from specific diseases by amount smoked: Ratio of observed to expected number of deaths of persons who had regularly smoked cigarettes only, by current amount smoked in 1954, July 1954-December 1956¹

Disease	Ratio of observed to expected deaths ²			Number of observed deaths

¹ Underlying and contributory causes of death.

² Expected number of deaths computed by multiplying the number of person-years exposure in each age group by the age-specific death rates from each cause of death (including underlying and contributory causes) of persons who had never smoked or who had used tobacco only occasionally.

no evidence that this group experiences a higher death rate from these respiratory diseases than do nonsmokers.

Nearly two-thirds of the deaths of persons who had used tobacco were attributed to diseases of the cardiovascular-renal system, including chronic nephritis, arteriosclerosis, hypertension, rheumatic heart disease, chronic endocarditis, and coronary occlusion, sclerosis, and thrombosis. The risk of dying from one or more of these diseases is 31 percent greater for regular smokers than for nonsmokers. Again, the risk is greater for regular cigarette users, especially those who have smoked only

cigarettes, than it is for users of other forms of tobacco. There is no indication that regular cigar or pipe smokers experience a higher death rate than nonsmokers.

The mortality ratios for cancer other than cancer of the lung are similar in magnitude to those for cardiovascular diseases except that the ratios for cigar and pipe smokers are as high as those for cigarette smokers. The mortality from these forms of cancer will be discussed in more detail below.

Smokers have no greater risk of committing suicide or of being killed in an accident than do nonsmokers.

Mortality From Specific Causes

As was pointed out above, the death rates for each of the specific diseases include all patients with the disease at the time of death, irrespective of whether or not it was considered the underlying cause. However, a disease was not coded in the absence of evidence that it was clinically active.

Diseases with a mortality ratio greater than 2.0, signifying a death rate more than double that for nonsmokers, are bronchitis, emphysema, and allied respiratory diseases, cirrhosis of the liver, ulcer of the stomach or duodenum, cancer of the prostate, and cancer of the esophagus and buccal cavity (fig. 6). Several studies have reported that heavy smokers also tend to drink alcoholic liquors excessively so that the increased death rate from cirrhosis of the liver may reflect the effect of the consumption of alcohol rather than any effect of cigarette smoking. An increased mortality of cigarette smokers from the other diseases mentioned has been reported in other studies also. An explanation of the high mortality ratio for cancer of the prostate is not apparent.

The death rates from the principal cardiovascular diseases are from 33 percent to 63 percent greater for regular cigarette-only smokers than for nonsmokers. No increase in mortality exists for chronic rheumatic heart disease or for chronic nephritis.

Mortality ratios by current amount smoked for men who were regularly smoking cigarettes only are shown in table 5. The number of observed deaths for several diseases is not large enough to establish that the mortality ratio for heavy smokers is significantly greater or less than the ratio for light smokers. Among these diseases are cancer of the stomach and cancer of the kidney, for which the death rates are lower for heavy than for light smokers, and cancer of the bladder, cancer of the pancreas, and leukemia, for which the death rates are higher for heavy smokers than for light smokers.

But for cancer of the lung and cancer of the buccal cavity and esophagus, the death rate increases rapidly with an increase in the average daily number of cigarettes smoked. The death rate from lung cancer for men who regularly were smoking more than a pack of cigarettes a

day is nearly 16 times the rate for nonsmokers (fig. 7). A similar, although numerically smaller, increase in the mortality ratio with an increase in the number of cigarettes smoked exists also for cancer of the buccal cavity (lip, tongue, mouth, pharynx) and esophagus.

The leading cause of death of the policyholders included in this study is coronary heart disease. Although no difference was found in the death rates for moderate and heavy smokers, those smoking more than 10 cigarettes per day, these rates are greater than that for persons smoking less than 10 cigarettes per day. The difference, however, is considerably less than the corresponding difference for lung cancer. The death rates from hypertension, cerebral vascular lesions, chronic nephritis, and chronic rheumatic heart disease are no higher for heavy than for light smokers.

Summary

1. This report summarizes the mortality experience of nearly 200,000 policyholders of U.S. Government life insurance from July 1954 through December 1956. All these policyholders served in the Armed Forces of the United States between 1917 and 1940.

2. The death rate from all causes for men who have used tobacco is 32 percent greater than that for men who have never smoked.

3. Men who have smoked regularly only cigarettes have the highest death rate of all groups of smokers, 58 percent greater than the rate for nonsmokers.

4. The death rate from all causes for men who have regularly smoked cigars or a pipe, or both, is not appreciably higher than that for nonsmokers.

5. Regular cigarette smokers who had stopped smoking cigarettes before the study began in 1954 have a lower mortality rate than those who continued to smoke. However, the rate for the ex-smokers still is 31 percent greater than that of nonsmokers.

6. The excess mortality of regular cigarette smokers is greater for heavy smokers than for light smokers. Only the heaviest users of cigars and pipe tobacco experience a significant increase in total mortality over that of men who have never smoked.

7. The greatest increase for smokers in the risk of developing a disease is for cancer of the lung. The mortality ratio for regular smokers of cigarettes only is 9.85, or about 10 times that for nonsmokers. The death rate for men smoking more than a pack of cigarettes a day is 16 times that of nonsmokers.

8. Regular users of cigars or a pipe, or both, have an increased mortality rate for cancer of the lung as well as for all forms of cancer as a group, but this increase is much less than that for cigarette smokers.

9. Regular cigarette smokers are subject also to an increased risk of dying from cardiovascular disease, from certain respiratory diseases such as bronchitis, pleurisy, and emphysema,

from ulcers of the stomach and duodenum, and from cirrhosis of the liver.

10. The death rate from coronary heart disease among regular users of cigarettes only is 63 percent higher than the rate for nonsmokers.

11. The leading cause of death among the policyholders is coronary heart disease. Forty-four percent of the number of observed deaths and 45 percent of the number of excess deaths—the difference between the number of observed deaths and the number of deaths expected on the basis of the rates for nonsmokers—for cigarette-only smokers were attributed to coronary heart disease. Corresponding percentages for lung cancer were 7 and 17.

Institutes in Care of Premature Infants

Announcement of the 1959-60 schedule of the institutes for physicians and nurses in the care of premature infants at the New York Hospital-Cornell Medical Center marks the 11th year of this service. The institutes are sponsored by the New York State Department of Health and the Children's Bureau.

Designed to meet the needs of physicians and nurses in charge of hospital premature nurseries and special premature centers, and medical and nursing directors and consultants in State and local premature programs, each course is limited in attendance to six physician-nurse teams. The program for physicians is of 2 weeks' duration and for nurses, 4 weeks. Participants pay no tuition and stipends are provided to assist with expenses during attendance.

Early application is essential for the 1959-60 institutes, which will start in 1959 on September 21 and November 2; in 1960, January 4, February 8, and May 9.

Additional information may be obtained by writing Box 143, Institute in the Care of Premature Infants, New York Hospital, 525 East 68th Street, New York 21, N.Y.

Mortality From Specific Causes

As was pointed out above, the death rates for each of the specific diseases include all patients with the disease at the time of death, irrespective of whether or not it was considered the underlying cause. However, a disease was not coded in the absence of evidence that it was clinically active.

Diseases with a mortality ratio greater than 2.0, signifying a death rate more than double that for nonsmokers, are bronchitis, emphysema, and allied respiratory diseases, cirrhosis of the liver, ulcer of the stomach or duodenum, cancer of the prostate, and cancer of the esophagus and buccal cavity (fig. 6). Several studies have reported that heavy smokers also tend to drink alcoholic liquors excessively so that the increased death rate from cirrhosis of the liver may reflect the effect of the consumption of alcohol rather than any effect of cigarette smoking. An increased mortality of cigarette smokers from the other diseases mentioned has been reported in other studies also. An explanation of the high mortality ratio for cancer of the prostate is not apparent.

The death rates from the principal cardiovascular diseases are from 33 percent to 63 percent greater for regular cigarette-only smokers than for nonsmokers. No increase in mortality exists for chronic rheumatic heart disease or for chronic nephritis.

Mortality ratios by current amount smoked for men who were regularly smoking cigarettes only are shown in table 5. The number of observed deaths for several diseases is not large enough to establish that the mortality ratio for heavy smokers is significantly greater or less than the ratio for light smokers. Among these diseases are cancer of the stomach and cancer of the kidney, for which the death rates are lower for heavy than for light smokers, and cancer of the bladder, cancer of the pancreas, and leukemia, for which the death rates are higher for heavy smokers than for light smokers.

But for cancer of the lung and cancer of the buccal cavity and esophagus, the death rate increases rapidly with an increase in the average daily number of cigarettes smoked. The death rate from lung cancer for men who regularly were smoking more than a pack of cigarettes a

day is nearly 16 times the rate for nonsmokers (fig. 7). A similar, although numerically smaller, increase in the mortality ratio with an increase in the number of cigarettes smoked exists also for cancer of the buccal cavity (lip, tongue, mouth, pharynx) and esophagus.

The leading cause of death of the policyholders included in this study is coronary heart disease. Although no difference was found in the death rates for moderate and heavy smokers, those smoking more than 10 cigarettes per day, these rates are greater than that for persons smoking less than 10 cigarettes per day. The difference, however, is considerably less than the corresponding difference for lung cancer. The death rates from hypertension, cerebral vascular lesions, chronic nephritis, and chronic rheumatic heart disease are no higher for heavy than for light smokers.

Summary

1. This report summarizes the mortality experience of nearly 200,000 policyholders of U.S. Government life insurance from July 1954 through December 1956. All these policyholders served in the Armed Forces of the United States between 1917 and 1940.

2. The death rate from all causes for men who have used tobacco is 32 percent greater than that for men who have never smoked.

5. Regular cigarette smokers who had stopped smoking cigarettes before the study began in 1954 have a lower mortality rate than those who continued to smoke. However, the rate for the ex-smokers still is 31 percent greater than that of nonsmokers.

6. The excess mortality of regular cigarette smokers is greater for heavy smokers than for light smokers. Only the heaviest users of cigars and pipe tobacco experience a significant increase in total mortality over that of men who have never smoked.

Some Epidemiological Considerations in Rocky Mountain Spotted Fever

CORNELIUS B. PHILIP, Ph.D., Sc.D.

When the following paper was presented in its original form at the 15th International Congress of Zoology, in London, July 1958, the audience included a number of Soviet scientists who were interested in the relation between Rocky Mountain spotted fever and Siberian tick typhus. This relationship has evoked a resurgence of international interest in the spotted fever group of tickborne diseases, reflected here through references to Price and others. Although this paper is limited to observations in the Bitterroot Valley, it was presented with the comment that data still in process at the Rocky Mountain Laboratory appear to confirm ecologic and etiologic similarities of Siberian tick typhus with Rocky Mountain spotted fever. A detailed table of hosts, which, as noted below, has been filed with the American Documentation Institute, was prepared specifically with regard to intensive studies by the Russians on rodent hosts of immature tick vectors.

IN the Bitterroot Valley of Montana, where the ecology of Rocky Mountain spotted fever has been longest under study, the common tick vector is *Dermacentor andersoni*, the immature stages of which feed on susceptible small animals. Adult ticks feed on relatively insusceptible large animals and accidentally infect man.

It has long been reported, and is still unexplained, that severe human infections have been acquired only on the west side of the Bitterroot Valley, and that elsewhere, also, levels of virulence vary consistently in different

parts of the range of *D. andersoni*. An average of only 1 to 3 percent of Bitterroot ticks, under varying environmental conditions, have been found to be infected in a 5-year intensive study made by Philip and Parker (unpublished paper). They also observed that the highest infection rate, 13.5 percent, in any one spot is among the precipitous, so-called "goat-rocks" on the west side.

Maintenance in Nature

In 1954 Price (1) reemphasized two factors that have long been considered by Ricketts, Parker, and others of prime importance in the natural persistence of the infectious agent: (a) transovarial passage through successive generations of the tick vectors, and (b) the starting of new lines of infection by the simultaneous feeding of infected and noninfected ticks on susceptible hosts, largely young rodents and rabbits or hares in the Rocky Mountain area of the United States. Since only part of the progeny of an infected female tick "inherit" the agent, Ricketts had logically calculated that the first factor alone would not adequately explain natural maintenance.

Furthermore, the mechanism of the second factor must be more limited than would appear on casual consideration. In the Bitterroot Valley, Columbian ground squirrels are the most numerous and important of the susceptible small animal hosts of immature *D. andersoni* (table 1), but significant differences of tick infestations on these or other rodents between the two sides of the valley are not apparent. Consideration of the difference between the biotic potential of the ticks (5,000 to 8,000 eggs per

Dr. Philip is principal medical entomologist and assistant director of the Rocky Mountain Laboratory, National Institute of Allergy and Infectious Diseases, Public Health Service, Hamilton, Mont.

east of Stevensville, found a tick on her thigh prior to characteristic severe illness from which she recovered. None of the four persons had himself been to the west side within a reasonable time, but circumstances did not eliminate possible indirect west side contacts of the unlikely nature described previously.

The circumstances in the other two cases appeared to remove any reasonable suspicion that west side ticks could have been concerned. One patient was an employee (G. B., 45 years) working on an east side ranch 1 mile east of Victor; the other (J. H., 67 years) was the owner of a ranch known to be tick infested 1½ miles east of Corvallis. Careful questioning found no evidence of visits or movement of stock and wood from the west side within a reasonable period. Neither person had been vaccinated against Rocky Mountain spotted fever. Both had histories of tick bite, with typical rash and fever, and both recovered.

A strain of spotted fever isolated from J. H. was of moderate virulence for guinea pigs through nine successive passages.

Recovery of a symptom-producing strain in guinea pigs from east side *D. andersoni* substantiates that cases can occur in that area. During one series of tests of adult ticks from Harlan Gulch southeast of Hamilton, 1 of 27 guinea pigs, each injected with 2 ticks partially laboratory fed and incubated, developed a fever on the fifth day and died on the ninth. Transfer of tissue from this guinea pig provided a fever-producing strain which was maintained for 27 passages, and its identity with other virulent strains was confirmed.

Nevertheless, the observation remains essentially true and still unexplained that a high proportion of Bitterroot Valley cases have originated from bites of west side ticks, although many people have been bitten by east side ticks.

Rapid Tick Passage

Strains of Rocky Mountain spotted fever have frequently been carried in the laboratory through continuous animal passages for many generations, but this has not previously been done with alternating cycles in ticks. A strain fully virulent for guinea pigs, which had been isolated from a western Montana patient in

May 1946, was selected for this study of the effect on virulence of rapid tick passage. This strain had never been passed in chick embryos but had been through 38 continuous passages in guinea pigs and then stored in the frozen state (dry ice at -70°C.) for 4 years.

In 1955 a series of alternating tick-guinea pig-tick passages was initiated by the simultaneous feeding of infected adult ticks and non-infected nymphs on hosts. Elimination of transovarial passage shortened the intervals needed for tick development in a given passage. In this manner it was possible to compress 13 animal passages due to 12 tick generations, held at room temperatures in humidity jars, into the unexpectedly short period of 25 months. Based on past experience with laboratory strains of differing virulence, the reactions and fatality rates in test animals were used to provide comparisons of virulence in tissue- and tick-infected guinea pigs. These criteria were also used by Price (1).

The uncomplicated histories of 27 guinea pigs infected within the first year after isolation and before freezer storage of the strain are available for comparison with 25 each infected afterward by spleen suspension and citrated blood. The first group of 27 had a mean incubation period of 3.52 days, and 59 percent died. For the second group, the mean incubation periods following spleen and blood injection were 2.76 and 3.32 days, respectively, and 44 and 56 percent died (table 2).

For comparison with these are the clinical records of 24 and 29 guinea pigs bitten by 1 pair each of infected ticks of the 10th and 13th generations. The mean days of incubation were 6.6 and 4.8 respectively, and the fatality rates were 62 and 83 percent. It is probable that most, if not all, of tick-bitten animals were infected by the bites of single females which had been applied 3 days before introduction of males to stimulate rapid and complete engorgement.

The spread in the mean incubation periods between the tissue-transfer and tick-bitten groups is surprisingly low when the more massive inoculums of the former are considered. Fatality after tick bite is actually a little higher. It is remarkable that 16 of 29 animals exposed to the 13th generation of ticks had in-

engorged female) and the observed natural balance (1 pair of adults replacing 1 female in the long run) is such that the tabulated 6.4 average larvae and nymphs per ground squirrel (in which rickettsemia has been shown to last only a few days in any 1 infected animal) will offer only limited support to the idea of new lines of infection. Recovered or immune animals do not contribute to this maintenance mechanism as reported by Price (1) and Philip and Parker (unpublished paper). Although minor yearly fluctuations in numbers of ticks were observed in a quantitative study, no marked increasing or decreasing trends in the local tick population have been observed over several seasons that would alter the above considerations (2).

A third mechanism which could enhance the starting of new lines of infection in areas where susceptible rabbits and hares are more abundant involves widespread infection in the rabbit tick *Haemaphysalis leporis-palustris* (3) and in *Dermacentor parumapertus* (4). All stages of *D. andersoni* also have been found on native hares and rabbits.

A fourth mechanism which has not been adequately explored but which probably assists in natural maintenance of the disease is transmission during copulation of adult ticks on large, mostly insusceptible animals. In 1933 Philip and Parker (5) showed that infected male ticks can pass infection to ova of uninfected females with the sperm. Since male ticks remain on their hosts after engorged females have dropped off, they can and do mate with more than one female over an unknown period, but the percentage of infection in resultant

larvae has not been checked. Until this rate of infection is known, this mechanism cannot be dismissed in the consideration of factors in the maintenance of *Rickettsia rickettsii* in nature.

East Side Human Infections

From the earliest days of settlement, the west side of the Bitterroot Valley has been known as the hazardous side as regards human infection. Most cases, although not all as reported by Price (1), have been in west side residents more or less repeatedly exposed to local ticks or in persons visiting the west side just prior to their illnesses. Very infrequently an east side resident has become ill without obvious west side contacts. Credulity is occasionally strained to reason that the offending tick was brought back from the west side by other members of a patient's household or by a crew of east side laborers who had made a west side visit. Nor is it likely that adult ticks, after once having attached to stock animals brought from the west side, would transfer to persons.

Between 1930 and 1938, there were at least six such "east side" cases. Two of these were in timber workers who contracted Rocky Mountain spotted fever in the lower east side hills in different areas and years. One died; the other, who recovered, had been vaccinated in previous years. A third case was in a 6-year-old girl living on an east side ranch. She had taken a trip to the lower east side hills the week before onset of the disease, which she survived. A tick was found in her scalp. The fourth, a housewife, 33 years, on a ranch 7 miles

east of Stevensville, found a tick on her thigh prior to characteristic severe illness from which she recovered. None of the four persons had himself been to the west side within a reasonable time, but circumstances did not eliminate possible indirect west side contacts of the unlikely nature described previously.

The circumstances in the other two cases appeared to remove any reasonable suspicion that west side ticks could have been concerned. One patient was an employee (G. B., 45 years) working on an east side ranch 1 mile east of Victor; the other (J. H., 67 years) was the owner of a ranch known to be tick infested 1½ miles east of Corvallis. Careful questioning found no evidence of visits or movement of stock and wood from the west side within a reasonable period. Neither person had been vaccinated against Rocky Mountain spotted fever. Both had histories of tick bite, with typical rash and fever, and both recovered.

A strain of spotted fever isolated from J. H. was of moderate virulence for guinea pigs through nine successive passages.

Recovery of a symptom-producing strain in guinea pigs from east side *D. andersoni* substantiates that cases can occur in that area. During one series of tests of adult ticks from Harlan Gulch southeast of Hamilton, 1 of 27 guinea pigs, each injected with 2 ticks partially laboratory fed and incubated, developed a fever on the fifth day and died on the ninth. Transfer of tissue from this guinea pig provided a fever-producing strain which was maintained for 27 passages, and its identity with other virulent strains was confirmed.

Nevertheless, the observation remains essentially true and still unexplained that a high proportion of Bitterroot Valley cases have originated from bites of west side ticks, although many people have been bitten by east side ticks.

Rapid Tick Passage

Strains of Rocky Mountain spotted fever have frequently been carried in the laboratory through continuous animal passages for many generations, but this has not previously been done with alternating cycles in ticks. A strain fully virulent for guinea pigs, which had been isolated from a western Montana patient in

May 1946, was selected for this study of the effect on virulence of rapid tick passage. This strain had never been passed in chick embryos but had been through 38 continuous passages in guinea pigs and then stored in the frozen state (dry ice at -70°C.) for 4 years.

In 1955 a series of alternating tick-guinea pig-tick passages was initiated by the simultaneous feeding of infected adult ticks and non-infected nymphs on hosts. Elimination of transovarial passage shortened the intervals needed for tick development in a given passage. In this manner it was possible to compress 13 animal passages due to 12 tick generations, held at room temperatures in humidity jars, into the unexpectedly short period of 25 months. Based on past experience with laboratory strains of differing virulence, the reactions and fatality rates in test animals were used to provide comparisons of virulence in tissue- and tick-infected guinea pigs. These criteria were also used by Price (1).

The uncomplicated histories of 27 guinea pigs infected within the first year after isolation and before freezer storage of the strain are available for comparison with 25 each infected afterward by spleen suspension and citrated blood. The first group of 27 had a mean incubation period of 3.52 days, and 59 percent died. For the second group, the mean incubation periods following spleen and blood injection were 2.76 and 3.32 days, respectively, and 44 and 56 percent died (table 2).

For comparison with these are the clinical records of 24 and 29 guinea pigs bitten by 1 pair each of infected ticks of the 10th and 13th generations. The mean days of incubation were 6.6 and 4.8 respectively, and the fatality rates were 62 and 83 percent. It is probable that most, if not all, of tick-bitten animals were infected by the bites of single females which had been applied 3 days before introduction of males to stimulate rapid and complete engorgement.

The spread in the mean incubation periods between the tissue-transfer and tick-bitten groups is surprisingly low when the more massive inoculums of the former are considered. Fatality after tick bite is actually a little higher. It is remarkable that 16 of 29 animals exposed to the 13th generation of ticks had in-

engorged female) and the observed natural balance (1 pair of adults replacing 1 female in the long run) is such that the tabulated 6.4 average larvae and nymphs per ground squirrel (in which rickettsemia has been shown to last only a few days in any 1 infected animal) will offer only limited support to the idea of new lines of infection. Recovered or immune animals do not contribute to this maintenance mechanism as reported by Price (1) and Philip and Parker (unpublished paper). Although minor yearly fluctuations in numbers of ticks were observed in a quantitative study, no marked increasing or decreasing trends in the local tick population have been observed over several seasons that would alter the above considerations (2).

A third mechanism which could enhance the starting of new lines of infection in areas where susceptible rabbits and hares are more abundant involves widespread infection in the rabbit tick *Haemaphysalis leporis-palustris* (3) and in *Dermacentor parumapertus* (4). All stages of *D. andersoni* also have been found on native hares and rabbits.

A fourth mechanism which has not been adequately explored but which probably assists in natural maintenance of the disease is transmission during copulation of adult ticks on large, mostly insusceptible animals. In 1933 Philip and Parker (5) showed that infected male ticks can pass infection to ova of uninfected females with the sperm. Since male ticks remain on their hosts after engorged females have dropped off, they can and do mate with more than one female over an unknown period, but the percentage of infection in resultant

larvae has not been checked. Until this rate of infection is known, this mechanism cannot be dismissed in the consideration of factors in the maintenance of *Rickettsia rickettsii* in nature.

East Side Human Infections

From the earliest days of settlement, the west side of the Bitterroot Valley has been known as the hazardous side as regards human infection. Most cases, although not all as reported by Price (1), have been in west side residents more or less repeatedly exposed to local ticks or in persons visiting the west side just prior to their illnesses. Very infrequently an east side resident has become ill without obvious west side contacts. Credulity is occasionally strained to reason that the offending tick was brought back from the west side by other members of a patient's household or by a crew of east side laborers who had made a west side visit. Nor is it likely that adult ticks, after once having attached to stock animals brought from the west side, would transfer to persons.

Between 1930 and 1938, there were at least six such "east side" cases. Two of these were in timber workers who contracted Rocky Mountain spotted fever in the lower east side hills in different areas and years. One died; the other, who recovered, had been vaccinated in previous years. A third case was in a 6-year-old girl living on an east side ranch. She had taken a trip to the lower east side hills the week before onset of the disease, which she survived. A tick was found in her scalp. The fourth, a housewife, 33 years, on a ranch 7 miles

³ Multiple tick feeding during 13 passages.

incubation periods as short as 2 to 4 days which could only have followed bites of single, unrefrigerated female ticks.

A comparison of various clinical features following various routes of infection is provided in table 2. No significant change was detectable after 13 generations of rapid tick passage, and the virulence of the strain for guinea pigs appeared to be fully maintained. It also appears that the virulence of the strain after 4 years' storage in the frozen state had not been markedly altered.

Tick Feces as a Source of Infection

Tick feces are considered a source of human infection with *Pasteurella tularensis* in tularemia (6) and with *Coxiella burnetii* in Q fever (7, 8), just as louse feces are a source of epidemic typhus. Experimental evidence indicates that infection with spotted fever among animal handlers is much less likely to occur through a similar agency.

Female *D. andersoni* ticks, during engorgement, customarily show a sequence of defecation of dry pellets for several days, then a rather viscous mass of altered blood, followed terminally by whitish plaques apparently of excretion from malpighian ducts.

Freshly excreted fecal pellets, masses, and plaques were collected at intervals from single,

female ticks while feeding on 12 different guinea pigs; each animal became infected as a result of tick bite and died of spotted fever. Collected feces were macerated on the moistened, intact or abraded skins of 68 test animals in 3 series of tests without producing infection. All animals were proved to be susceptible. Fecal suspensions in physiological saline from only two of the four ticks in one series caused infection when injected intraperitoneally into other guinea pigs at least 5 to 9 days after attachment, prior to which early feces from even these two ticks were noninfectious by injection (table 3).

Attempts To Infect Fleas and Mosquitoes

The tropical rat flea *Xenopsylla cheopis* is the well-known vector of the endemic typhus agent, *Rickettsia typhi*. It was of interest to test adaptability of *R. rickettsii* of spotted fever to this flea or to indigenous rodent fleas in order to investigate the possibility that they might play a secondary role in natural maintenance. Dr. William L. Jellison of the Rocky Mountain Laboratory assisted in some of these earlier studies.

X. cheopis fleas were fed for 6 days during pyrexia in a fatally infected guinea pig. Transmission was not effected by injection of 6 freshly fed fleas, by transfer of 28 fleas to a

capsule on a new animal where they were observed feeding on the 8th and 12th days, or by injection of 1 living and 5 recently dead fleas from this animal after 21 days into another guinea pig.

Similar tests with the common woodchuck flea, *Thrassis acamantis*, gave negative results in 2 series of tests by injections of 1 to 13 fleas after various intervals, by immediate transfer, during interrupted feeding, of 13 fleas between a donor with fever and scrotal lesions and a new animal; and by transfer of other fleas to a new host after several days on the donor. At least three fleas remained active for as long as 9 days on the second host, and a suspension of these was noninfectious when injected into a third.

Tests of transmission by four lots of the rabbit flea, *Cediopsylla inaequalis*, also proved negative. Two lots of fleas were fed on infected domestic rabbits with fever and orchitis for 6 and 10 days, and allowed to transfer from sacrificed donors to fresh rabbits. After 13 days on the new hosts, one flea from each failed to infect additional rabbits by bite, or guinea pigs after injection. Fleas of the other two

lots were permitted in a similar manner to transfer from laboratory-infected, native cottontail donors to domestic rabbits without causing infection. Injections of fleas from both donor and test rabbits into guinea pigs up to 37 days were noninfectious. Tissues of both donor cottontails produced disease when injected into guinea pigs at time of transfer of fleas.

Mosquitoes have been observed feeding on hares in nature (9) and will undoubtedly accept opportunities to attack rodents as well. However, three lots of *Aedes aegypti* failed to become infected when fed on infected donor guinea pigs, according to tests by bites and injection during 14 days' storage at room temperature.

It is apparent that neither fleas nor mosquitoes, at least under conditions of these tests, are likely vectors of Rocky Mountain spotted fever rickettsiae in nature.

Summary and Conclusions

Mechanisms of natural maintenance of spotted fever rickettsiae are reviewed in the light of new information and with relation to the fauna

Table 3. Sample results of tests with tick feces during separate engorgement of two female *Dermacentor andersoni*

¹ 1 hour's fresh deposit from each tick used in aliquot portions for transfer on each day. ² Donor guinea pig had 6 days of incubation, 2 days of fever, and died on the 10th day. ³ Donor guinea pig had 4 days of incubation, 6 days of fever, died on the 12th day.

of the Bitterroot Valley of Montana. Contrary to some reports, evidence is presented for the possible exceptional contraction of human infection and the occasional occurrence of relatively virulent strains on the east side of the valley. Although data continue to support accumulated observations that virulent spotted fever is mainly prevalent on the west side, an adequate explanation, ecological or otherwise, for this difference is still not apparent.

To check any possible effect on virulence, a strain of Rocky Mountain spotted fever was used to infect guinea pigs in 13 rapid passages through bites of 12 alternate generations of *Dermacentor andersoni* compressed into a period of 25 months. Uninfected, immature ticks were fed simultaneously with infected adults during each fresh guinea passage to establish each new generation. The infection rate in test animals was as effective following paired tick feedings as in using direct blood or spleen transfers. There appeared to be little significant change in virulence after 13 alternating tick passages, as judged by comparison of clinical data. However, the fatality rate was a little higher following tick feeding than after tissue passage.

Feces of ectoparasites are not as potential a source of infection in spotted fever as they are in certain other tickborne diseases, such as Q fever and tularemia, or as in louseborne typhus fever. Neither fleas of three different species nor aedine mosquitoes appeared to be adaptable to an incidental role in natural maintenance of the agent, though important rodent hosts carry over an average period many more fleas than ticks and are probably frequently bitten by indigenous mosquitoes.

It is possible that some of these observations will apply to Siberian tick typhus also. Not only is the ecology of that disease more similar to spotted fever than to tickborne fièvre boutonneuse and related diseases in Europe, Africa, and India, but comparative etiological studies in progress substantiate this difference in relationships.

The Public Health Nurse As Coordinator in a Geriatric Clinic

ESTELLE T. MALACHOWSKI, P.H.N.

THE GOAL of the geriatric clinic of the San Francisco Regional Office of the Veterans Administration is to help the patient and prevent the necessity of hospitalization or institutional care as long as possible.

The clinic's patients are veterans of the Spanish-American War. Under Public Law 791, 81st Congress, they are eligible to receive medical supervision and appropriate coordinated services. These men, whose median age is 79 years, challenge the clinic to give them more years to live. Confronting geriatrics in the future are the veterans of World War I, whose median age is 66 years. This group does not have the blanket type of outpatient medical care plan provided for the older veterans.

The clinic, opened in 1952, was the first of its kind in the Veterans Administration. The pilot study report, "Coordinated Approach to Geriatrics," is also the first recorded attempt to demonstrate a team approach to geriatrics in a regional office of the Veterans Administration (1). The clinic provides facilities and therapeutic accommodations in medicine, public health nursing, physical therapy, nutrition, social service, and psychiatry. Its personnel collaborate with staff specialists, consultants of the regional office, and regular visiting consultants from the local medical society, and with community agencies to give the veteran the care he requires.

Miss Malachowski is a public health nurse coordinator and health education counselor in the outpatient clinic of the Veterans Administration Regional Office, San Francisco, Calif.

The complications of illnesses, disabilities, and personal and social difficulties of the Spanish-American War veteran are often multiple. To help him with these, the geriatric clinic has a team of specialists consisting of the chief of the clinic, public health nurse, social service worker, physical therapist, psychiatric consultant, and medical secretary.

Clinic sessions are held each Tuesday from 9 to 11:30 a.m. The physical setting includes a clinic room used for other clinics at other times, a waiting room which seats 10 patients, the office of the public health nurse, an emergency bedroom, a surgical unit, and a central supply unit.

Prior to his initial visit to the clinic, the patient has been given a complete physical examination by the staff geriatric consultant, and medical and laboratory records are ready for review. At the clinic the new patient is first interviewed by the public health nurse, whose previous hospital experience and education in public health have prepared her to act as counselor to the patient and coordinator of the clinic's services.

She takes the patient's blood pressure, pulse, and weight, recording them as well as other pertinent information that will be valuable to the geriatric team. But perhaps her most important job in this 20-minute interview is to communicate the clinic's approach to the patient and determine his attitude toward accepting treatment and instruction.

She may notice that the patient is neatly dressed and well groomed, that he appreciates

a comment on his appearance, that he exhibits some stiffness of joints as he seats himself, and that he wears glasses and dentures. But she is also aware that he is a person, with varying physical and mental abilities, needs, feelings, attitudes, and capacities.

Past experience has taught the nurse that one of a patient's foremost fears is "what the doctors found or what laboratory findings revealed." Her own behavior in this conversation may either intensify those fears and anxiety or stimulate revelations which may prove pertinent.

Many interviews have taught her that older people love to talk about their experiences and sometimes it is difficult to focus their attention on a question long enough to get a direct answer. Often, patience and tact are necessary to recall the patient to the original question, although permitting the patient to ventilate his emotions has a therapeutic value.

The nurse's goal in the first interview is to present to the clinic team a profile of the patient's immediate medical problems and his economic, social, and cultural background, and to explain to the patient the various services of the clinic and the regional office. On the patient's first visit she will merely outline these services. At subsequent interviews and referrals to other medical and nursing services, she will devote more time to clarifying the scope of services, utilizing visual aids and emphasizing health measures. After the interview the patient is escorted to the waiting room to be called later to the clinic room.

The nurse then joins the team in the clinic room and listens to the medical review of the patient presented by the staff geriatric consultant, the chief of the clinic. The anecdotal record of the nurse-patient interview is also read. After evaluation of both reports, the patient is escorted into the clinic room and introduced to the staff. The chief of the clinic explains the team approach to the patient and its significance to his health and welfare. The patient is then given a future appointment for medical supervision, and arrangements are mapped out for the integrated services of the team according to the chief of clinic's recommendations. Clinic visits are usually 4 to 5

weeks apart. Approximately 10-12 patients attend each weekly session of the clinic.

The nurse has a short conference with the patient after he has left the clinic room to ascertain his reaction to this type of medical care and to be sure he understands the medical orders. Occasionally she finds he has already been prepared for the clinic by his friends in the waiting room or has heard about it from his comrades in the Spanish-American War veterans organization. A majority of those veterans hold office or attend meetings of the various camp units along the California coast.

The nursing assistants of the regional office are unofficial members of the geriatric team, but they assist in many ways. The male nursing assistant, under medical and nursing supervision, gives direct service to the patient in minor surgery, genitourinary treatment, proctoscopic examinations, and orthopedic steroid therapy. He prepares the patient and the instruments for these treatments, and, before a physical examination, helps a patient who may have difficulty in undressing. The nursing assistants help not only in the geriatric clinic but in other specialized clinics and in the general medicine practiced in the regional office.

Services Within the Regional Office

As counselor and coordinator, the nurse explains the medical program of the regional office and other services of the Veterans Administration to the patient during subsequent visits. The patient may have been referred by the chief of the clinic to have his eyes examined, his hearing tested, or his dentures examined. The nurse is aware of the importance of prosthetics and sensory aids to these patients. For example, when she noticed a significant drop in the weight of one patient, he confided to her that his dentures were loose, and he only wore them during his clinic visit. He had been eating baby food for the past few months. This information was brought to the attention of the clinic physician who referred the patient to the dental clinic.

The mental hygiene unit of the regional office provides a psychiatrist who conducts group therapy for the geriatric clinic patients. A social worker acts as co-leader. The patients

meet informally with the psychiatrist before the clinic sessions begin.

Responses to the group therapy vary. The patients are remarkably self-reliant and reticent in discussing their difficulties before a group. Usually the discussions center around the trials inherent in caring for their aging wives or about their difficulties in adjusting to being a secondary member of someone else's household. When they talk about themselves, they are surprised and relieved to realize they have so much in common with others.

Many surgical services are available to the patients of the geriatric clinic, and surgery can be scheduled at the mutual convenience of patient and surgeon. The surgeon on the staff is qualified in general, plastic, hand, genitourinary, proctological, and orthopedic fields. In general, hand, and plastic surgery, biopsy and diagnostic procedures can be performed. Diagnostic proctological procedures such as sigmoidoscopy, biopsy, treatment of thrombosis, and external anal afflictions, and genitourinary procedures such as care and followup of external urinary fistulae, soundings, and strictural dilations are done in the surgical clinic. In orthopedics, controlled steroid injection therapy is administered to multiple joints.

Since discontinuance of the nutrition service in 1955, the clinic nurse has assumed the responsibility, with the cooperation of the chief of the clinic, of reevaluating diets at appropriate intervals. Each diet is modified to conform to changing medical requirements and to the patient's tolerance for certain foods.

Other services are available to the patient in such special fields as allergy, dermatology, arthritis, urology, tuberculosis, diabetes, orthopedics, prosthetics, and sensory aids. Special needs are determined by the chief of the clinic and appropriate referrals are made.

Extramural Services

The hometown medical care program of the Veterans Administration is the extramural service for patients of the geriatric clinic and for eligible veterans of the two World Wars and the Korean conflict who are unable to travel to the regional office or who may require emergency care. In fiscal year 1956, more than 554,000 VA patients received hometown medical

care at a cost of \$6,290,133. Of this amount, \$699,735 was spent to care for 62,769 veterans of the Spanish-American War (?).

All geriatric clinic patients, and especially those with a history of heart disease, are informed about the hometown medical care program. The nurse explains the communication necessary between the physician in the patient's community and the authorization officer in the regional office. The patient is also reminded to make his immediate family aware of the program so that they can act in an emergency. The assurance that medical services can be provided in their homes is important to these patients. As they grow older, their homes are more important to them and severance of ties with them are often traumatic.

In an emergency, communication between the authorized fee-basis physician (usually the family physician) attending the patient at home and the chief of clinic may provide the fee-basis physician with the current medical diagnosis, history of illness, and results of laboratory tests, and thus prevent expensive, repetitive tests and examinations.

Fee-basis physicians are usually selected by the patient, and in most instances are the family physician. If the patient does not have his own physician, the Veterans Administration provides him with a list of three in his community, and he selects one of these. At the present time the selection of physicians is limited to those who are members of the California Physicians Service.

Community home nursing services are an important component of the hometown medical care program. The regional office, which has contracts with various community health agencies, can arrange for home visits by members of a visiting nurse association. If there is no such agency in the area where the patient lives, visits by a registered nurse or a licensed vocational nurse can be arranged.

The clinic, the hospital, or the authorized fee-basis physician may indicate the need for home nursing services. The referral for such services, made by the chief of the clinic, may be for the purpose of administering special medication intramuscularly or for followup of prescribed treatment that has been demonstrated to the patient by the clinic nurse. If

a comment on his appearance, that he exhibits some stiffness of joints as he seats himself, and that he wears glasses and dentures. But she is also aware that he is a person, with varying physical and mental abilities, needs, feelings, attitudes, and capacities.

Past experience has taught the nurse that one of a patient's foremost fears is "what the doctors found or what laboratory findings revealed." Her own behavior in this conversation may either intensify those fears and anxiety or stimulate revelations which may prove pertinent.

Many interviews have taught her that older people love to talk about their experiences and sometimes it is difficult to focus their attention on a question long enough to get a direct answer. Often, patience and tact are necessary to recall the patient to the original question, although permitting the patient to ventilate his emotions has a therapeutic value.

The nurse's goal in the first interview is to present to the clinic team a profile of the patient's immediate medical problems and his economic, social, and cultural background, and to explain to the patient the various services of the clinic and the regional office. On the patient's first visit she will merely outline these services. At subsequent interviews and referrals to other medical and nursing services, she will devote more time to clarifying the scope of services, utilizing visual aids and emphasizing health measures. After the interview the patient is escorted to the waiting room to be called later to the clinic room.

The nurse then joins the team in the clinic room and listens to the medical review of the patient presented by the staff geriatric consultant, the chief of the clinic. The anecdotal record of the nurse-patient interview is also read. After evaluation of both reports, the patient is escorted into the clinic room and introduced to the staff. The chief of the clinic explains the team approach to the patient and its significance to his health and welfare. The patient is then given a future appointment for medical supervision, and arrangements are mapped out for the integrated services of the team according to the chief of clinic's recommendations. Clinic visits are usually 4 to 5

weeks apart. Approximately 10-12 patients attend each weekly session of the clinic.

The nurse has a short conference with the patient after he has left the clinic room to ascertain his reaction to this type of medical care and to be sure he understands the medical orders. Occasionally she finds he has already been prepared for the clinic by his friends in the waiting room or has heard about it from his comrades in the Spanish-American War veterans organization. A majority of those veterans hold office or attend meetings of the various camp units along the California coast.

The nursing assistants of the regional office are unofficial members of the geriatric team, but they assist in many ways. The male nursing assistant, under medical and nursing supervision, gives direct service to the patient in minor surgery, genitourinary treatment, proctoscopic examinations, and orthopedic steroid therapy. He prepares the patient and the instruments for these treatments, and, before a physical examination, helps a patient who may have difficulty in undressing. The nursing assistants help not only in the geriatric clinic but in other specialized clinics and in the general medicine practiced in the regional office.

Services Within the Regional Office

As counselor and coordinator, the nurse explains the medical program of the regional office and other services of the Veterans Administration to the patient during subsequent visits. The patient may have been referred by the chief of the clinic to have his eyes examined, his hearing tested, or his dentures examined. The nurse is aware of the importance of prosthetics and sensory aids to these patients. For example, when she noticed a significant drop in the weight of one patient, he confided to her that his dentures were loose, and he only wore them during his clinic visit. He had been eating baby food for the past few months. This information was brought to the attention of the clinic physician who referred the patient to the dental clinic.

The mental hygiene unit of the regional office provides a psychiatrist who conducts group therapy for the geriatric clinic patients. A social worker acts as co-leader. The patients

their services under the community nursing program. This was an increase of \$8,251 over the 1954 cost to the Government and is evidence of the increased use of the home nursing service. But this represents an important reduction in the cost to taxpayers when compared with the cost of the hospital care that would be required."

Volunteer Service

The San Francisco regional office has an active volunteer service of 35 members who represent various organizations. Two volunteers are from the auxiliary unit of the United Spanish War Veterans. The geriatric clinic patients know them both as widows of men who have been active in camp affairs. They package gauze abdominal pads, applicators, and other requested materials, meeting a quota of 3,000 packages a month which are sent to eligible veterans.

They assist in other ways. For example, recently the colonel, a 94-year-old veteran who lives alone in a single room, seemed to be getting weaker by the day and was confused at times. He had an ambivalent feeling about going to the California State veterans home and had twice canceled plans to go there. Each afternoon for 3 weeks he hobbled eight blocks to the regional office and reported to the emergency bedroom to rest and eat the milk and crackers the volunteers served him.

Concerned about him, one of the volunteers contacted his friends in the camp and explained the colonel's predicament. When the camp members visited him, he said he wanted to go to the veterans home, but was worried about his thousand pounds of baggage. The members assured him they would take care of his belongings. Although the physician, nurse, and social worker had tried before to arrange domiciliary care, the colonel was not ready to move until the camp members, alerted by the volunteer, took action.

Two of the volunteers are men. One has charge of the storage and distribution of various health pamphlets to racks throughout the building. The other, a retired pharmacist, gives his time in the pharmacy packaging stock medicines which are sent by mail to veterans whose physicians have requested the medicine.

The regional office has found that volunteer duty is a useful form of rehabilitation in geriatrics and should be encouraged. Assigning a volunteer a definite responsibility and making sure he knows that others are depending on him gives him satisfaction in his work.

Conclusions

The experiences of the public health nurse in the geriatric clinic have been rewarding. She uses skills in health education, teaching, interpreting physicians' orders, and planning with the patient.

She understands that the patient of advanced age has many needs. Indirectly she has shared many of the problems of these patients and has tried to give them guidance. She has learned that they wish to remain independent and assume responsibilities, despite physical and social stresses.

She has learned how these veterans acquire hobbies to compensate for lonely hours, and how they fulfill social needs in the camps of the Spanish-American veterans' organization.

The clinic provides an insight into the geriatrics of the future. The Spanish-American War veteran has challenged the clinic to give him more years to live. The World War I veteran, on the periphery of geriatrics, presents a similar challenge.

home care is needed following a hospital stay, the ward nurse usually explains the home nursing care that is available. Final arrangements for home visits are the responsibility of the chief of the nursing unit of the regional office, who is familiar with the resources of the neighboring communities. Fee-basis physicians' requests for home nursing service go to the chief of the nursing unit of the regional office.

The following case report illustrates the importance of continuity of medical and nursing care in the home.

Mr. W., 83 years of age, had been attending the geriatric clinic for about 5 years. In November 1956 he complained of chest pains and a "loose cough." His established diagnosis was arteriosclerosis and hypertension. An X-ray revealed a mass in the right side of his chest. He was referred to the nearest Veterans Administration hospital for further studies, and the final diagnosis was pulmonary metastasis, primary, undetermined. The hospital physician explained to Mr. W.'s wife and daughter that further treatment was impossible because of the patient's age and the possible complications.

After Mr. W. was discharged from the hospital, the family physician requested weekly home nursing visits for general bedside care, intramuscular injections, and health guidance to the family. Mr. W.'s wife, 80 years of age, and unmarried daughter, 50, who supported the family financially and did the housekeeping as well, were eager to have supportive care.

The chief of the nursing unit contacted the visiting nurse service by telephone, and home nursing care for Mr. W. was started within an hour. The visiting nurse reported to the regional office that the wife and daughter had received her warmly. She had instructed them in maintenance therapy to prevent decubiti, joint stiffness, and loss of self-care ability and pointed out the importance of keeping medicine beyond Mr. W.'s reach, for he became confused at times.

She reported the family had missed Mr. W. when he was hospitalized, were happy to have him at home, and felt they could care for him with a little help from her. Mr. W. stated he would soon recover since he was at home. The visiting nurse association submits a monthly

bill of \$16, and the fee-basis physician's home services cost \$24 a month. Each visits Mr. W. four times a month.

This case demonstrates the teamwork of the hospital, family, fee-basis physician, the community service agency, and the staff of the regional office in the extramural medical treatment program of the Veterans Administration. The visiting nurse is in close contact not only with the attending physician but with the chief of nursing unit in the regional office. Medical orders, prescribed treatment, health instruction to the family, evaluation visits, determination of the number of visits, and environmental factors are discussed with the chief of the nursing unit at intervals.

From the patient's standpoint, the success of the home nursing care is measured by the satisfaction he derives from it. About one-fourth of the cases on record in the regional office are those of Spanish-American War veterans. Periodic telephone calls to patients have assured the office that they are satisfied with the home nursing service.

Dr. E. M. Bluestone has said that when we permit a patient who has reached the terminal stages of his illness, and who still enjoys illusions of hope, to be maintained in familiar surroundings where he can be cared for by himself and his family, we are moving in the right direction in extramural service (3).

In fiscal year 1954, 932 patients throughout the VA received home nursing care at a total cost of \$88,001.82. The average cost per visit was \$2.58, which was considerably below that required to maintain a patient in a general medical and surgical hospital during that fiscal year. Average hospital cost for this period was \$19.84 per day (4).

The number of patients who receive community nursing service has increased since the program was organized. According to a report in *Nursing Outlook* (5), "The monetary value of home nursing services cannot be estimated in terms of the individual veteran's and the community's health and happiness. The average fee per visit was \$2.67 in 1955, which is an increase of 9 cents over the 1954 and 18 cents over the 1952 cost per visit. The Government paid a total of \$96,251 to contracting public health agencies in the fiscal year 1955 for

A demonstration underway in Connecticut is proving the value of voluntary consultation as a means of upgrading the standards of community hospitals.

A Project in Voluntary Consultation for Hospitals

JOHN T. FOSTER, M.P.H., and JANE HARTMAN, M.S.

IN 1955, leaders of the Connecticut Hospital Association felt that a need existed among their 33 short-term, member hospitals for guidance in dietary and personnel practices. An application was submitted to the Public Health Service requesting a grant whereby two specialists could be added to the staff of the association to provide voluntary consultation services to member hospitals.

The application stated, "There exists today a hiatus in most parts of the country between the recommendations of the experts and the actual operation in the individual hospitals. Most hospitals are small and cannot afford highly trained department heads or experts in all fields to take advantage of the many recommendations. This is particularly true in personnel and dietetics." The application further stated, "The value would be measured not only by improved personnel and dietary practices, but also through financial savings in the individual hospitals."

Mr. Foster, assistant administrator at the Stamford (Conn.) Hospital, was a student in the Yale University program in hospital administration at the time of the study. Miss Hartman serves as food service specialist in the project for improved dietary administration at the Connecticut Hospital Association. The study was supported by a Public Health Service research grant (W-7, C-2).

A 2-year grant was awarded in April 1956, and, based on initial results of the project, a 1-year extension was approved. The association is studying the possibility of financing the program on its own on a permanent basis.

Consultation services, as such, are not new. In hospital administration alone consultants flourish on a fee-for-service basis in many fields, including architecture, dietetics, fund raising, public relations, personnel, and accounting. These private consultants may have difficulty in obtaining clients. Once they have a contract in hand, however, they gain psychological advantage over the client, who is anxious to justify expense by obtaining value in return.

A similar receptivity is enjoyed by another type of consultant, the specialist working under the auspices of governmental regulatory agencies. When consultation is coupled with licensing, there is an implied sanction that would seem to give the consultant some advantage in acceptance.

Voluntary consultation, lacking both the financial involvement of the client and the sanction of licensing, is acutely dependent upon the effectiveness of the consultant and the degree of the client's need. This potential weakness of the project was recognized by the association at the outset.

A retrospective evaluation of the first 18 months of the dietary phase of the two-part

Epidemiological Notes

Plastic Film Hazard

Filmy plastic bags, used by dry cleaners and food packagers, were brought to public attention as a household hazard when Dr. James F. Benedict of Erie County, N.Y., was quoted in the *New York Times*, August 29, 1958. He referred to two infants suffocated by such wrappers.

At the October 1958 meeting of the National Safety Council, a delegate issued a warning and mentioned an accidental suffocation said to have been caused by a plastic bag. Four more deaths were cited by Dr. Paul B. Jarrett, chairman of the Maricopa County Medical Society Accident Prevention Committee, in the *Arizona Republic* of January 4, 1959. All of these were infant deaths occurring in the vicinity of Phoenix. Later in January, Dr. A. B. Rosenfield of the Minnesota Department of Health reported to the press that two infants had been suffocated by makeshift pillow covers made from plastic bags.

The use of the bags as covering for bedding appears to have been a contributing factor in many of these infant suffocations. In other cases, babies have managed to grasp plastic bags lying nearby. Suffocation occurs when the limp film clings to the mouth and nostrils. Even toddlers, playing with this thin plastic, have become enmeshed in it and suffocated themselves. The increase in such deaths corresponds with the rise in sales of thin plastic bags. The dry cleaning industry alone bought 600 million in 1958 but almost none in 1955.

In early February 1959, a letter directing attention to the Arizona report was circulated in the medical and health field by Dr. B. H. Conley, secretary of the Commission on Toxicology, American Medical Association. On February 26, the Public Health Service began investigation by requesting its regional offices to seek further information on incidents of this nature through State health departments.

During March, April, and May, reports of more accidental suffocations appeared in quick succession. Additional cautionary statements were issued by health agencies, officials of local medical societies, the National Institute of Dry Cleaning, and the Society of the Plastics Industry. Following the suffocation of a 10-week-old infant in Windsor, Ontario, the Canadian Press reported May 24 to the *New York Times* that the dry cleaning concern affected is abandoning the use of plastic wrappers.

A telegraphic survey of State health officers by the National Safety Council on April 20 brought to light at least 20 accidental suffocations since January 1, 1959, which were reported on the death certificates as due to some sort of plastic film. By the end of May the list of such tragedies had grown to 35 for 1959, according to information received by the Accident Prevention Branch of the Public Health Service. At that time, the known count for 1958 and 1959 was 55 accidental suffocations and 3 suicides reported to have involved plastic film.

The Public Health Service began epidemiological investigation of deaths reported from this cause early in May with the cooperation of State and local health departments. Results of intensive study of seven of these deaths have convinced Service officials of the need for public education to prevent future tragedies of this kind. A cautionary leaflet, "Plastic Film—Correct Use and Mis-use," prepared in cooperation with public and professional organizations by the Society of the Plastics Industry, is available without charge for distribution through public health agencies.

Despite the apparent involvement of plastic film, it is not clear that mechanical suffocation was the true cause of death in all the instances mentioned for 1958 and 1959. A wholly accurate measure of the death toll from plastic film would have been possible at this time only if all infants who died in circumstances suggesting suffocation from it had been examined postmortem by pathologists. In the past, studies of sudden deaths of infants have demonstrated that a significant proportion of those believed due to mechanical suffocation may have resulted from acute respiratory infections, such as tracheobronchitis and acute interstitial pneumonia. In view of these facts, postmortem examination of infants believed to have died from mechanical suffocation is highly desirable.

Of the 51 individual standards on the check-sheet, only 3 items were complied with by all the hospitals. All hospitals met the requirement that modified, therapeutic diets be ordered in writing by the physician, and that available funds be provided for nutritionally adequate meals.

At the same time, not one of the 33 hospitals met the ADA standard specifying that the dietitian write comments on the patient's medical chart, obviously a matter of regional medical practice of long standing. Only 24 percent of the hospitals were conducting adequate inservice training.

The class III hospitals were notably low in organization and personnel practices. But they ranked high in facilities and conferences, and ranked well in the remaining categories. These differences seem significant. One can understand relatively low ratings in staffing for the two groups of smaller hospitals, since qualified dietitians are a requirement. Few of these, one can speculate, have been able to obtain or afford dietitians. Funds alone do not explain the deficiencies in the smaller hospitals, however, as demonstrated in the relatively high standing of these groups in facilities where they exceeded the scores of the class II hospitals. The class II group was especially interesting; while ranking high with class I in staffing, it fell below norms in other areas. It should be noted here, however, that this group's deficiency in facilities was already being attacked through a number of building or remodeling programs to which they were committed in the fall of 1956.

Averages are useful as an indication of general patterns, but can hide wide variations within a group, and this is true of the arbitrary groupings that have been used. Class I and class II hospitals in particular ranged widely in their total scores on the checksheet completed by the specialist in her early visits. While two class I hospitals ranked high, with 47 of a possible 51 points, one hospital in the group ranked with the lowest with only 20 total points. A hospital in class II had the lowest total score of all 33 hospitals, a total of only 14 points of compliance.

In addition to observing checksheet phases of dietary operation, the specialist found that other dietary problems existed in enough of the

hospitals to make additional goals important. Such a problem was scheduling of the patient's meals. One criterion of hospital care applies to the minimizing of the inevitably large number of adjustments a patient must make as he enters the hospital world. The average patient might be expected to complain when he finds breakfast arriving between 6:30 and 7:00 a.m., a heavy meal arriving at 11:30 a.m., and a light "supper" arriving at 4:00 or 4:30 p.m. Schedules such as this were all too common.

Sanitation and housekeeping were covered by the checksheet, and the specialist was struck by the severity of some of the problems in this area. Several problems were architectural, but the majority were the result of attitude. Compounding the difficulties was the fact that few cities provided really close inspection by sanitarians. The overall average compliance of 48 percent with the item on regular inspection by a sanitarian seems somewhat inflated when it is recognized that once-a-year inspections were accepted as the norm by the specialist. Most would argue that regular inspection at least twice a year plus in-between "drop-ins" should be a minimum. Such standards were, however, typical of the Connecticut communities as she found them. At one large teaching hospital the specialist found a model purchasing procedure for canned foods. Purchasing was based on carefully prepared specifications, bidding was competitive, and sample cans were "cut" and evaluated for color, flavor, composition, and other criteria under carefully controlled conditions. Contrasted with this model system for assuring both quality and maximum use of the available food dollars, few hospitals were using competitive purchasing for either quality or cost control. This, therefore, became another area of concentration and subsequent service.

The checksheet covered standardized cost accounting for food only in general terms. This became still another area of effort, in which the specialist was aided by the Connecticut Hospital Association's accounting specialist throughout the study.

In summation, a wide variance in compliance with standards of the American Dietetic Association was found in Connecticut hospitals.

project was undertaken as an academic project by the senior author, a student in the course in hospital administration of the department of health, Yale University. The final report records notable gains in a majority of the hospitals. The achievements indicate that voluntary consultation can be effective when properly organized and conducted.

Start of the Project

As the food service specialist, the Connecticut Hospital Association selected a member of the American Dietetic Association who had been food service director with the Maryland State Department of Health. Her services began in September 1956 with a "get acquainted" visit to each of the 33 hospitals and a survey of the quality of their dietary programs.

To provide a frame of reference for the project, the sponsors selected the "checksheet for the hospital department of dietetics," devised by the American Dietetic Association. The checksheet, considered a summation of essential criteria, represented exhaustive study and research by a special committee of the association beginning in 1954.

The checksheet represented 51 items divided into 6 main categories of dietetic administration. The six areas of special interest but of varying degrees of relative importance were organization, facilities, personnel, records, management policies, and conferences.

Items related to organization were designed to evaluate the qualifications of the dietitian and the effectiveness of supervision. Sample questions were: Is there a written organization plan designating areas of authority? Is supervision designated for all working hours?

Regarding facilities, the items recorded the way the food was received, stored, prepared, cooked, and served. Dishwashing and disposal equipment and methods were judged as well as the adequacy of the size of dining areas and communication equipment.

Questions on personnel determined, for example, whether the department was subject to a labor-hour budget, whether the nonprofessional personnel assignments were evaluated periodically to assure sufficient employees, and whether there was an adequate number of stenographers and clerks so that professional staff

time was not used for these duties. The application of an employee merit-rating system was also checked.

The items on records asked about the accessibility of pertinent records and checked practices in accounts and inventory recordings. The following were representative queries: Is a record of all menus, as served, filed for a reasonable time? Are regular and modified menus checked for nutritional adequacy and patient acceptance? As an alternative to a perpetual inventory system, is an adequate inventory of another type maintained? Has the dietitian access to medical charts?

Sample questions under management policies asked the following: Are all patients on routine and modified diets visited at frequent intervals? Do you use written communications to make suggestions, to confirm oral discussions and decisions, to present reports, and as reminders?

The conference group of items measured the level of communications and cooperation among the dietetic, administrative, and medical staffs of the hospital. The following questions were representative: Does the dietitian in charge of the department of dietetics attend the administrator's conferences? Are staff conferences for the department of dietetics held periodically?

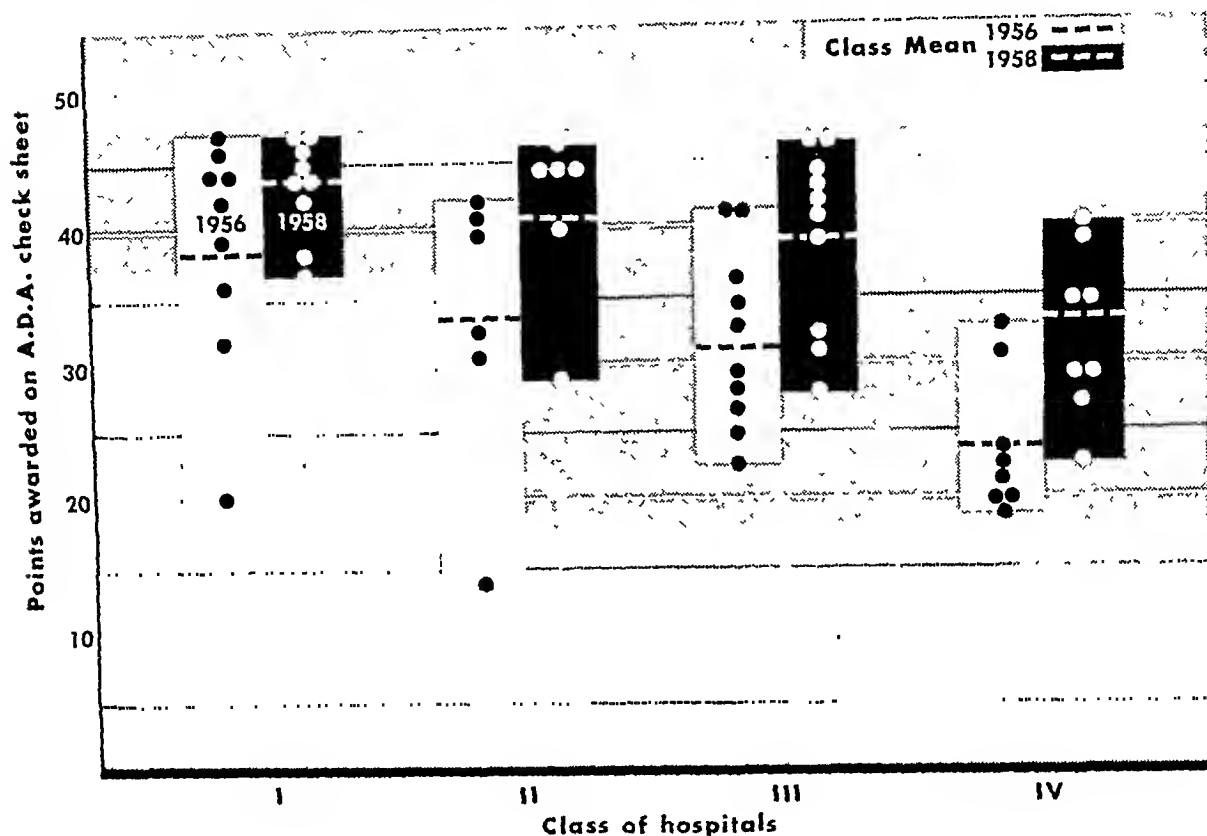

Subsequent to the Connecticut hospital study, the checksheet was expanded and refined to increase its utility as a measurement tool for dietary consultant services on a continuing basis.

The 33 hospitals were grouped by size because of the wide range in number of beds (and thereby of financial structure). The size ranged from more than 700 to fewer than 40 beds. The four categories established were class I, with 300 or more beds, 9 hospitals; class II, 200 to 300 beds, 6 hospitals; class III, 100 to 200 beds, 10 hospitals; and class IV, 99 or fewer beds, 8 hospitals.

Initial Survey Results

The initial survey in 1956 disclosed a wide range of compliance with the 51 individual items among Connecticut hospitals, from a low of 14 "right answers" for one to a high of 47 for another. The mean score was 31.9 and the median 31.

Figure 1. Comparison of raw scores¹ in initial survey (1956) and in followup survey (March 1958) made by 33 member hospitals of the Connecticut Hospital Association.

¹ Ratings by dietary specialist.

A major item under staffing is the requirement that the hospital dietary department be headed by a qualified dietitian. The fact that this was unchanged quantitatively during the study period (15 of the 33 hospitals met the requirement) does not reflect the extent to which the dietary consultant helped recruit dietary personnel. Three qualified dietitians were recruited to replace head dietitians who resigned during the period, and 12 subordinate dietary supervisors were found. Other improvements in the category of organization brought the score for this area from 49 to 65 percent despite the lack of change in the one requirement.

Gains noted in the other areas were facilities, 62 to 84 percent; personnel, 52 to 71 percent; records, 70 to 81 percent; management, 65 to 73 percent; and conferences, 62 to 69 percent.

Several hospitals at the end of the report period had greatly improved the scheduling of meals for patients so that there is no more

than 14 hours between the serving of the evening meal and breakfast. Notable throughout the State were the generally higher levels of housekeeping and sanitation. These resulted from the direct consultations and inspections by the specialist, and particularly from the in-service training programs which were developed by many of the hospitals based on the training outlines the specialist had prepared and published.

In cooperation with the hospital association's accounting specialist, a monthly food cost analysis report was developed. By the end of the report period the majority of larger hospitals in the State were submitting these reports. The reporting required standardization of food cost accounting practices in these hospitals, which in turn reflected the increasing awareness of the importance of controlling food cost.

In one hospital, the specialist found that al-

In general, larger hospitals ranked more favorably than the smaller hospitals, but this was not true in all cases for all criteria. Conditions were not "bad," but it was clear not only to the food service specialist but also to others associated with her that the original premise of the application had been valid. The administrator of one hospital, a member of the project committee, commented: "I was appalled to think that some of the things I have heard about could exist in our hospitals." Not all conditions were appalling, but certainly the survey confirmed the need expressed in the original application for improved dietary administration. The challenge and the opportunity to improve conditions were clear.

Consultation Methods

A consultant in a field such as dietetics can approach a client with either of two basic methods: with a "package program" for the client to accept or reject, or with an open mind for the client's interpretation of his needs and an attempt thereupon to find solutions tailored to his situation. The latter method is more passive and also meets the accepted criterion of teaching—that people learn more readily when they are participants in selecting the topic. It also places greater demands upon the consultant's adaptability and professional skills, although most consultants will tend to combine both methods in varying degrees. It was the second approach that primarily characterized the consultations provided by the dietary project.

Working both with the administrator and the dietitian of the hospital, the food service specialist made a total of 290 consultation visits. This averaged four per working week, and when travel time is included each visit took the better part of a working day.

Training conferences for the dissemination of new methods and for the sharing of solutions to problems was, from the beginning, one of the expectations of the sponsors. Five statewide meetings, one of these lasting an entire working week, and 14 regional meetings were held during the 18 months.

As the specialist became increasingly involved in the need for inservice training, in addition to conducting 15 demonstration train-

ing sessions, she prepared a series of training guides which were distributed to all member hospitals. These guides were also published in the *Modern Hospital*, May 1958.

From the outset, a written report was maintained on activities and progress. Also, a detailed narrative report summarizing each consultation visit was made part of the association's permanent file.

Further demands upon the food service specialist came not only from her professional affiliations but from a variety of State groups. Demonstrating the latent demand for guidance in this professional area, these requests were for consultations with special hospitals affiliated with the Connecticut Hospital Association, with State institutions, and with nursing homes.

Other unanticipated functions which took on increasing importance as the various hospitals gained confidence in the service offered were those of architectural consultation and equipment planning. Ambitious building programs of the hospitals created the need for the specialist's professional guidance that administrators found useful over and above the advice of architects and even of paid food service consultants. In one notable case, the dietary specialist reduced a hospital's equipment costs for a new kitchen by about \$75,000.

Resurvey Results

The resurvey of the hospitals at the end of the first 18 months of the dietary project showed an upward shift of standings. From an overall compliance of 62 percent in 1956, the mean for the 33 hospitals climbed to 76 percent in early 1958. Only 1 of the 33 hospitals failed to improve its score, a class I hospital with a near-perfect score of 92 percent in the first survey. The range in raw scores which had covered 65 percent of the scale in 1956 decreased to 46 percent in 1958 (fig. 1).

The mean scores of the hospital classes increased from 38.8 to 43.3 in class I; from 33.2 to 41.2 in class II; from 31.7 to 39.2 in class III; and from 23.5 to 32.1 in class IV. As expected by the sponsors, the largest proportional gains occurred among the smaller hospitals.

Gains were also made in each of the special areas in every hospital class.

were, in 1956-57, at a peak in Connecticut as the result of the Hill-Burton program and, to a lesser extent, the hospital grants of the Ford Foundation. Eight of the 33 hospitals were already committed to major reconstruction or expansion at the outset of the dietary project.

In an effort to arrive at a more direct relationship between the dietary project and improved facilities, figure 2 shows three values: the 1956 compliance with facilities criteria, the gross compliance in the 1958 survey, and a "without construction" score for 1958 from which the more obvious effects of capital improvement have been deleted. While smaller, the gains again occur consistently in each hospital class.

Acceptance of the Specialist

Fully aware of the need to establish acceptance, the specialist made clear to each administrator that her services were available. There was wide variation in the response.

At the various educational conferences, a total of 546 persons attended. They included 90 administrators in addition to the dietary personnel. All hospitals were represented in at least one of these meetings and 80 percent of class I hospitals participated in the statewide meetings. The larger hospitals, however, were represented by more people than the smaller at these conferences. The smaller hospitals, on the other hand, were less apt to have professional dietitians and proved therefore to be the most responsive to professional guidance. The hospitals with building programs made the greatest demand for equipment and layout advice.

The relationship between the specialist and the administrators reflected a wide range of attitudes on the part of the administrators. There were those who were unwilling to acknowledge any problems, those who requested advice but were unable to apply it, and still others who were receptive to advice and effective in putting guidance into practice.

A Case in Point

An idealization of effective consultation is the experience with a 70-bed hospital, where much

was achieved and credited by the administrator to the specialist.

In addition to improving dietary services, a major hope of the sponsors had been to reduce dietary costs. In this hospital, the adoption of controls and rescheduling of personnel brought these financial changes:

<i>Year ending</i>	<i>Salary and wages</i>	<i>Supplies and expenses</i>	<i>Total</i>
September 1956 -----	\$38,322	\$38,682	\$77,004
September 1957 -----	34,662	30,983	65,645
Reduction -----	3,660	7,699	11,359

Significantly, this hospital was the only one of the 33 to reduce the total costs per patient-day during the years in question. The reduction was about equal to the amount saved in the dietary department. Unquestionably, inefficiency had existed there before, but it was the specialist who brought it to the attention of the administrator and showed him ways to correct his problems.

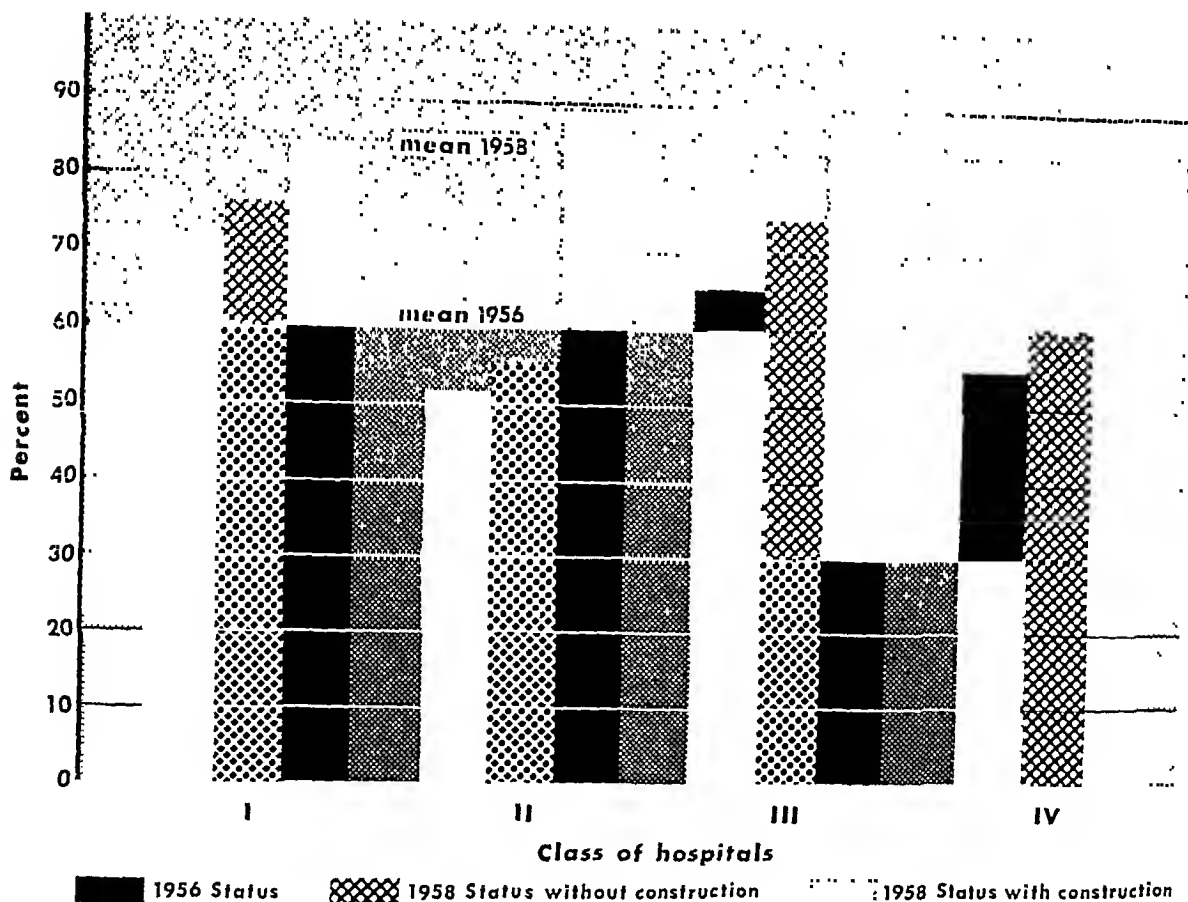

In the period under survey, this hospital (*a*) adopted a written organization plan designating supervisory responsibilities; (*b*) rearranged storage space; (*c*) obtained more efficient kitchen equipment; (*d*) improved dishwashing procedures; (*e*) instituted systematic equipment maintenance and replacement; (*f*) placed the dietary department on a budget; (*g*) adopted new menus for improved nutrition and patients' acceptance; (*h*) began nutritional education for patients; (*i*) provided a food preference system for each patient; and (*j*) adopted inventory controls.

Success Factors

The Connecticut demonstration has more than met the expectations of its sponsors. Although not every one of the member hospitals made maximum use of the proffered services, requests for service from member hospitals have accelerated beyond the heavy demand of the first 18 months. What are the factors that made the program work?

Qualifications of the food service specialist. Voluntary consultation places heavy importance on the ability of the consultant to obtain the respect of both professional peers (in this case, dietitians) and of business-oriented administrators. At the cost of a 5-month delay,

Figure 2. Comparison of percentage compliance by hospital classes with checksheet standards for facilities for 1956 and for March 1958.

though the dietary department maintained high food standards, the actual responsibility for preparing and serving breakfast rested with the housekeeping department, which served the noon and evening trays prepared by the dietary department. After a man-hours study, this hospital was able to revise the entire system, so that the full responsibility rested with the dietary department, at no increased cost in personnel. It is generally accepted that there is a particular advantage in placing full responsibility on the dietary department for the condition of the food as it reaches the patient. Similar special studies were conducted in other hospitals, to the same end, and in addition in-service training and regional educational programs all helped instill in the dietary personnel increased awareness of the importance of not only preparing the food well, but of serving it attractively.

Although direct cause and effect relationships between the dietary project and these improvements cannot be proved, the consistency of the changes suggests more than circumstantial evidence of the program's value. Other influences cannot be denied. All hospital administrators are subject to constant pressure to improve services. Certainly, a constant barrage of ideas in all aspects of hospital administration is presented by a variety of publications and professional associations. Many of these influences had existed long before the dietary project but did not obtain wide acceptance in the area until this individual consultation service program began.

In one specific area, however, a clear bias in the results is evident. This was in the improvement of facilities. The largest gains were noted here. It is necessary to recognize the effect of hospital construction projects which

The immediate past president of the American Medical Association reports on organized medicine's programs in the fields of chronic illness, aging and health care of the aged, school health problems, and medical research.

American Medical Association Report

GUNNAR GUNDERSEN, M.D.

SINCE its founding in 1847, the American Medical Association has steadily expanded its activities and services aimed at furthering the organization's primary objectives "to promote the science and art of medicine and the betterment of public health." These programs have multiplied at an ever faster rate during the past 30 years of rapid medical progress.

The changing dimensions of medical knowledge and the accelerated pace of technological progress already have made it difficult for physicians, public health workers, and other health personnel to keep abreast of scientific advances. Now the picture is being further complicated by a multitude of social, economic, and legislative problems which require intensified effort by all concerned.

More than ever before, medicine is intertwined with the worlds of business, industry, labor, government, economics, public opinion, and public affairs. In meeting this situation, the American Medical Association for more than a year has been reorganizing its administrative structure in order to serve both the profession and the public with the greatest possible efficiency and awareness. Under seven

Dr. Gundersen, who completed his term June 9, 1959, is the 112th physician to serve as president of the American Medical Association. With three of his five brothers who are also physicians, he operates the Gundersen Clinic in La Crosse, Wis.

new divisions, business, law, field service, communications, scientific publications, scientific activities, and socioeconomic activities, approximately 40 or more councils, bureaus, committees, and departments will be engaged in a coordinated effort to solve current and future problems in medicine.

It would be impossible in this article to cover even the highlights of all these programs, which were detailed in 300 pages of annual reports in the House of Delegates handbook at the AMA clinical meeting in December 1958. This report, therefore, will focus attention on what the association is doing in such fields as chronic illness, aging, school health problems, and research.

Chronic Illness

The medical and public health progress of the past half century has brought drastic cuts in the incidence and death rates of most communicable diseases. It has sharply reduced infant and maternal mortality. On a wide front it also has produced countless advances against many other diseases that once were serious health problems. As a result, average life expectancy at birth has increased about 23 years since 1900, and there has been a steady rise in the proportion of people living into middle and old age.

Consequently, general medical emphasis in

the Connecticut program was allowed to begin only after the sponsors were satisfied that they had found a consultant with the right personal and professional qualifications.

Existence of real need. Stimulus for the Connecticut project was the increasing participation of food management firms in hospital dietary programs. The fact that such firms could move into an area of hospital administration and demonstrate economic savings in spite of their fees signaled the existence of inefficiencies that needed correction. The fact that fewer than half of the Connecticut hospitals had been able to obtain professional direction for their dietary departments was a further clue to the potential value of a program that could be considered a sharing of professional knowledge and skills.

Acceptance of consultation. An accounting consultation service instituted by the hospital association in 1948 was a great advantage to the Connecticut program. This had led to a highly satisfactory program of uniform hospital accounting from which all hospitals had benefited. The success of this project had prepared the ground for acceptance of other consultation services.

Geographic accessibility. It is recognized that Connecticut offers a compact geographic pattern within which a program such as this could operate under near ideal conditions.

There is a real question as to whether a consultant could cover a larger area. Certainly, 33 hospitals are a maximum caseload. This suggests that in larger States regional hospital councils would offer an appropriate center for such a service.

Summary

To make available professional guidance in the areas of dietary and personnel administration to its 33 member general hospitals, the Connecticut Hospital Association was granted funds by the Public Health Service for a demonstration program. Based on initial results, a year's extension to August 1959 has been granted. The association is now studying the possibility of financing the program thereafter on its own.

With the services of a food service specialist, the program resulted in a variety of training conferences throughout the State, the recruiting of professional personnel, guidance to hospitals in new construction and equipment purchasing, and a marked upgrading of standards.

The results of the program would seem to demonstrate that consultation on a voluntary basis is at least as effective as consultation services by State agencies and by fee-for-service firms. Such consultation would seem, furthermore, to be a valid function of the State or regional hospital association.

PHS Nursing Research Program Expanded

The extramural nursing research program of the Public Health Service will be expanded by six new grants and support continued for three projects now underway.

Improved patient care through studies of nursing practice, nursing education, administration of nursing services, and other factors affecting the welfare of patients is the objective of the program, which was instituted in 1955.

The project sites of the six newly approved grants are Cornell University, University of California Medical Centers at Los Angeles and at San Francisco, University of Utah, and Western Interstate Commission on Higher Education, Boulder, Colo.

Grants for nursing research are administered by the Division of Nursing Resources in cooperation with the Division of General Medical Sciences of the National Institutes of Health.

developing a series of guides to aid all physicians in making proper determinations under both public and private disability insurance programs. Two of these guides already have been approved and made available to the profession.

As a final example, the Committee on Rehabilitation, with representation from several AMA councils, has outlined objectives and guides for intensified activity by the entire medical profession in the field of rehabilitation. To implement these, our House of Delegates in December 1958 approved a comprehensive plan of action for State and county medical society committees on rehabilitation.

Aging and Care of the Aged

During the past decade or more, the association's increased activity in the field of chronic illness led naturally to realization of the fact that a very large proportion of chronic illness occurs among people in the older age groups. Meanwhile, the growing number of senior citizens, plus a variety of social, economic, and political factors, began to focus more and more attention on health problems of the aged. Accordingly, the AMA House of Delegates in 1954 recommended the establishment of a Committee on Geriatrics, which was formed the following year.

At its very first meeting, however, this committee decided that it could not limit its scope to problems involved in the diagnosis and treatment of older patients. It recognized that practically no diseases are specifically or exclusively diseases of old age, and it saw that it had to think in terms of both the sick and the well. It defined its province as all facets of the aging process, physical, mental, emotional, social, occupational, cultural, and economic, and its name was changed to the Committee on Aging.

Since that time, in coordination with other committees on indigent care, medical facilities, and health insurance and prepayment plans, the AMA Committee on Aging has developed an expanding, intensified program of activities. Beginning in late 1956, it has sponsored a series of six regional conferences on aging, the latest of which was held in May 1959 in Salt Lake City. Basic purpose of these conferences,

which will continue in the future, is to present problems, stimulate medical and lay interest, learn local viewpoints, and promote the creation of active medical society committees on aging.

To speed progress, the AMA in June 1958 approved a set of suggested guides for medical society committees on aging, which provide a blueprint for organization, action, and co-operative projects. By the end of January 1959, all State medical societies and numerous county medical societies had formed such committees.

Through meetings, conferences, and continuing contact, the association has developed liaison with the Department of Health, Education, and Welfare, Public Health Service, American Nursing Home Association, American Hospital Association, Council of State Governments, National Committee on Aging of the National Social Welfare Assembly, Gerontological Society, University of Michigan Division of Gerontology, Federal Council on Aging, and many other national and State agencies interested in care of the aged.

An important result of the liaison with the American Nursing Home Association is the effort to establish and maintain high standards of medical care in nursing homes. Toward this objective, AMA staff members are making a field survey of 50 nursing homes in 22 States. Concurrently, the ANHA is conducting a questionnaire survey of about 4,500 member homes throughout the country. It is hoped that the results of these two surveys can be published this summer. On the basis of these findings, the AMA will formulate recommended guides and standards for medical care in nursing homes.

Following up on the regional meetings that began in 1956, the association last September held a national planning conference for medical society action in the field of aging. It attracted more than 175 representatives of 27 State health departments and of medical societies in 46 States and the District of Columbia. The conference approved a six-point AMA positive program calling for:

- Stimulation of a realistic attitude toward aging by all people.
- Promotion of health maintenance programs

recent years has been shifting from the infectious, communicable diseases, which used to be the great killers during infancy, childhood, and youth, to the cardiovascular diseases, cancer, arthritis, and the various forms of chronic illness and disability which can occur at any age. This trend also has produced greater attention to rehabilitation, disease prevention, and health maintenance in its most positive aspects.

As individual physicians and investigators began to center more attention on the problems of chronic illness, the American Medical Association moved to provide organized leadership in cooperation with other interested agencies. In 1946 the American Medical Association, American Hospital Association, American Public Health Association, and American Public Welfare Association established the Interim Committee on Chronic Illness. Three years later, this committee became the Commission on Chronic Illness, with representation from the general public, industry, labor, agriculture, education, religion, social sciences, journalism, health, and welfare.

The commission conducted and published numerous studies in the field of chronic illness, some of them in close cooperation with the Public Health Service. When the commission was disbanded in June 1956, the AMA continued to work on various phases of the problem. Our Council on Medical Service, for example, still publishes the *Newsletter on Chronic Illness*, which now goes bimonthly to about 6,500 groups and individuals making up a cross section of medical and allied health fields. The *Newsletter* emphasizes community programs and approaches in the area of long-term illness but now is being expanded to include more material of national scope.

The association continues to collect and maintain a resource file on chronic illness problems and answers a wide variety of requests for information. An important part of this work involves the development of organized home care programs, which provide a comprehensive array of medical, social, and rehabilitative services for patients who do not need all the services of a hospital. The AMA has published an expanded, revised edition of a 1957 survey of organized home care programs in the United

States. The new report covers the operation of 38 such programs currently underway in various parts of the country.

For several years the association has been gathering facts about central information and referral services for the chronically ill. These agencies, designed to serve patients, physicians, and all others concerned with the problems of chronic illness, function as community clearing-houses, and they also assist in factfinding studies and program planning. A survey of five such information centers now operating in Chicago, Milwaukee, Cleveland, San Francisco, and Essex County, N.J., is scheduled for publication. The AMA objective is to help promote widespread development of such centers in order to bring about better coordination in attacking the variegated problems of chronic illness.

In many ways and from various directions, numerous AMA councils and committees concern themselves with chronic illness problems. The Committee on Indigent Care, for example, publishes a steady stream of articles, surveys, and reports dealing with public assistance programs, which by their very nature involve care in chronic illness or disability. The AMA is urging all State and county medical societies to take an active part in assisting the efficient development and operation of the medical aspects of public assistance programs. Guides for medical societies have been formulated to help that effort. In a new policy action in December 1958, the association also recommended that States be permitted to combine the present four public assistance medical programs into a single medical program, administered by a single agency and making uniform services available to all eligible recipients.

The Committee on Medical and Related Facilities, among other activities, gathers facts about chronic illness facilities and nursing homes. As a result of its exhaustive study of the Hill-Burton hospital construction program, completed last year, the AMA is urging that States be given greater flexibility in meeting their needs for chronic illness facilities and nursing homes.

On still another front, the association's Committee on Medical Rating of Physical Impairment is engaged in a long-range project of

State medical societies have been urged to cooperate actively in development of the State conferences on aging which will precede the White House Conference on Aging in 1961. The association is working closely with the Department of Health, Education, and Welfare in this whole program, as well as in the development of homemaker services and nursing home classification systems. A highlight of the AMA June 1959 annual meeting in Atlantic City was a special scientific session on the medical aspects of aging. The association is pushing distribution of a new health appraisal form to stimulate increased physician participation in health maintenance programs. And the AMA itself plans sponsorship of a number of regional conferences on aging for medical, paramedical, and lay groups at some time in the near future.

In short, the American Medical Association is working hard to provide leadership for a concerted, positive, voluntary effort in the field of aging.

School Health Problems

Always interested in the health of school children, the AMA since 1911 has been cooperating actively with the National Education Association in the Joint Committee on Health Problems in Education. This committee, which met at AMA headquarters in March 1959, works to gain interprofessional recognition of principles and policies affecting the health of school-age Americans. Its findings and opinions are publicized by both of the sponsoring organizations.

As far back as 1918, AMA representatives on the joint committee were influential in declaring health to be the first of seven objectives in education. In 1922 the association declared in favor of periodic health examinations for all persons, including the school-age child. Since 1923, when the AMA began publishing *Hygeia*, now called *Today's Health*, this consumer magazine has been used to focus attention on a wide variety of school health subjects. For many years, as an aid to teachers, the association's Bureau of Health Education prepared discussion questions based on articles in *Today's Health*, which were widely used as classroom material in health education.

Independently and in partnership with the NEA, the American Association for Health, Physical Education, and Recreation, and the American Association of School Administrators, the AMA makes numerous contributions through periodic literature, pamphlets, and monographs dealing with school-age health. It also has been responsible in whole or in part for five major books: "Health Education," "Healthful School Living," "School Health Services," "Health in Schools," and "Fit To Teach."

Since 1926, the association has cooperated with the National Congress of Parents and Teachers in its program for child health, and there always has been an AMA representative on the PTA National Committee on Summer Roundup, recently renamed Child Health.

Maintaining continuous liaison, five traveling representatives of the AMA Bureau of Health Education attend or participate in numerous conferences, workshops, symposiums, panel discussions, and other activities involving school health. With the assistance of the association, an increasing number of medical societies are conducting similar activities at the State and local level through school health committees or other units. Individual physicians are active on boards of education, in school and community health conferences, parent-teacher programs, and cooperative projects with public health officers.

A focal point and clearinghouse for information is the National Conference on Physicians and Schools, held every 2 years under AMA sponsorship. These biennial conferences, which began in 1947, now attract more than 200 representatives of medical societies, health departments, school systems, and national voluntary or Government agencies. Plans are now underway for the Seventh Conference on Physicians and Schools to be held in October 1959.

The association's new Committee on Injury in Sports is developing a comprehensive program to safeguard the health of high school and college athletes. A special Committee on Amphetamines and Athletes is studying the use of such drugs as they relate to athletics. The AMA also is represented on the President's Citizens' Advisory Committee on the Fitness of American Youth.

and wider use of restorative and rehabilitative services.

- Extension of effective methods of financing health care for the aged.
- Expansion of training programs for skilled personnel and improvement of medical and related facilities for older people.
- Amplification of medical and socioeconomic research in problems of the aging.
- Leadership and cooperation in community programs for senior citizens.

It was agreed that the multiple activities necessary to implement this program must be carried out with effective medical leadership, a coordinated approach based on State and local needs, and strong effort to prevent isolation of the aged as a separate group in the human family.

Last November the AMA began distribution of 25,000 copies of "Medicine's Blueprint for the New Era of Aging," a booklet based on the six-point positive program presented at the planning conference. A conference report also has been widely distributed, and a new exhibit, based on the six-point program, has been shown at several National and State meetings of interested groups. The exhibit is being scheduled for numerous future showings.

As the AMA stepped up its own aging program, it also joined last year with the American Hospital Association, American Dental Association, and American Nursing Home Association in forming the Joint Council To Improve Health Care of the Aged. Pooling efforts of the four sponsoring groups, the council will study needs, resources, and programs in the field of aging. A working conference was held last February to plan for the council's first national conference, which attracted approximately 500 participants on June 12-14, 1959, in Washington, D.C. The AMA also is urging medical societies to promote the formation of State joint councils.

Meanwhile, in the area of legislation, the association has taken an active interest in constructive measures related to health care of the aged. Strong support was given to the legislation passed by the 85th Congress calling for a White House Conference on Aging to be held in January 1961, to be preceded by State conferences.

One of the medical profession's major objectives in the field of aging is to extend and improve voluntary health insurance, which already provides coverage for more than 40 percent of the population over 65 years of age. For several years the AMA has been urging experimentation in special types of health insurance coverage for the aged, and since last June it has intensified its liaison efforts with Blue Shield, Blue Cross, insurance companies, and other agencies in the prepayment field.

To expedite the growth of effective voluntary health insurance or prepayment coverage for people over 65 years of age with modest resources or low family income, the AMA House of Delegates in December 1958 adopted a proposal urging all physicians to adjust their charges to a level that will permit the development of insurance and prepayment plans at a reduced premium rate for persons now in that population group.

The association has urged all State and county medical societies to implement that policy. By March 1959 at least eight State societies had taken positive steps, and many more were expected to follow suit at annual or special meetings this spring and fall. The Blue Shield Medical Care Plans, which have a special committee studying all phases of the problem, recently developed a model insurance contract for persons over 65 years of age, incorporating the principle of the AMA policy action. The Health Insurance Association of America is urging all member companies to develop special and continuing coverage for retired persons. In recent months a number of private insurance companies either have announced new policies for the aged or have extended existing policies to more and more States.

Developments in this area are moving at a rapid, accelerating pace. The Health Insurance Association of America estimates that 60 percent of our senior citizens, who want and need it, will have protection by the end of next year. The figure is expected to rise to 75 percent in 1965 and 90 percent by 1970, but actual growth may exceed these conservative estimates.

Meanwhile, the AMA is planning for the future in all aspects of the aging problem. All

The prevalence of tuberculin sensitivity indicates a high infection rate in the lower Yukon area. Comparison with results in two Southern States suggests that tuberculin reactions should be interpreted according to the prevalence of nonspecific sensitivity.

Tuberculin Sensitivity and Tuberculosis Among Natives of the Lower Yukon

GEORGE W. COMSTOCK, M.D., D.P.H., and MERILYS E. PORTER, R.N., M.P.H.

TUBERCULOSIS has been the major health problem of Alaska natives for a long time. Only in the past few years can it be considered to have been brought under control in the sense that facilities for diagnosis, isolation, and treatment of infectious cases are now reasonably adequate.

Aside from the obvious fact that the prevalence of tuberculous infection and disease is extremely high, little is known of the epidemiological aspects of tuberculosis among the native population. Some information regarding tuberculin sensitivity among Alaska natives was obtained during two BCG vaccination programs, one by Aronson in southeastern Alaska in 1938 (1) and the other by the Alaska Department of Health from 1948 to 1951 (2).

Because of the limited information on this subject, it appeared desirable to report the results of a tuberculin survey of the villages along the Yukon River during the spring of 1957.

Both authors are with the Bureau of State Services, Public Health Service. Dr. Comstock is epidemiologist, Tuberculosis Branch, and Miss Porter is chief nurse of the Epidemiology Unit, Arctic Health Research Center, Anchorage, Alaska. (Manuscript received for publication March 10, 1959.)

In addition, the relationship of the size of tuberculin reaction to the prevalence of tuberculosis in this and other populations has important implications for the interpretation of tuberculin sensitivity.

Material and Methods

The original purpose of the tuberculin testing was to obtain baseline data regarding the prevalence of infection prior to the initiation of a controlled trial of isoniazid prophylaxis in the Bethel area of Alaska. This area included the deltas of the Yukon and Kuskokwim Rivers, and is bounded on the west by the Bering Sea, and in the interior by lines from Goodnews Bay and Unalakleet to McGrath (fig. 1). Because the testing teams were available for only a short time before the spring breakup of ice would make travel temporarily impossible, their efforts were concentrated in the villages in the northern half of the area to take advantage of the fact that breakup normally occurs a little later along the Yukon than along the Kuskokwim.

The tests were given and read by three experienced nurses from the tuberculosis program of the Public Health Service, assisted by the

Research

Through its councils on drugs, foods and nutrition, medical physics, mental health and scientific assembly, and committees on research, pesticides, toxicology, and cosmetics, the AMA is continually reporting on research advances in its scientific publications and at its annual and clinical meetings.

In addition to these extensive activities, the association's Committee on Research is engaged in a program of cooperative clinical investigation and collaborative reporting. This approach is being applied to the study of problems in which no one investigator has a large enough series of cases to warrant publication of conclusive findings. The subcommittees on breast and genital cancer, diabetes and pregnancy wastage, and blood dyscrasias are gathering and analyzing case reports in their spheres of interest. A new Subcommittee on Publications is being considered to solicit original articles, abstracts, and reviews dealing with research advances in the basic medical sciences. Through its Committee on Research the AMA has been active in stimulating nationwide interest in the problem of staphylococcal infections in hospitals. The association conducts a grants-in-aid program to supplement existing research projects, making 88 awards which totaled approximately \$30,000 last year.

The AMA right now is studying ways and means of improving and expanding its activities in the entire field of research. The American Medical Research Foundation has been established to initiate and encourage necessary medical research and to correlate and disseminate the results of studies already underway. As soon as legal and financial technicalities are

settled, the foundation will embark on a program which the AMA hopes will be an effective, vital force in the Nation's research effort.

In another action related to research, the association's House of Delegates in December 1958 recommended the creation of a mechanism which will assume the responsibility for promoting active liaison with each national medical society. "In the scientific fields," the house declared, "the role of the AMA should be primarily that of leadership, but every endeavor should be made to bring about coordination of the special fields of scientific interest of the other national medical organizations." Within its own administrative structure, the association also is planning to establish a research department that will concentrate on socioeconomic problems.

Going beyond our national boundaries and demonstrating a sincere interest in the promotion of international health, the American Medical Association is giving full, enthusiastic support to the current legislation which would establish a national advisory council for international medical research and a national institute for international medical research.

Conclusion

The four areas covered in highlight fashion, chronic illness, aging, school health, and research, represent only a fraction of the American Medical Association's total activity aimed toward public and professional service. It is hoped, however, that this report reflects the spirit of progressive, positive action in which the AMA views present and future medical problems.

The prevalence of tuberculin sensitivity indicates a high infection rate in the lower Yukon area. Comparison with results in two Southern States suggests that tuberculin reactions should be interpreted according to the prevalence of nonspecific sensitivity.

Tuberculin Sensitivity and Tuberculosis Among Natives of the Lower Yukon

GEORGE W. COMSTOCK, M.D., D.P.H., and MERILYS E. PORTER, R.N., M.P.H.

TUBERCULOSIS has been the major health problem of Alaska natives for a long time. Only in the past few years can it be considered to have been brought under control in the sense that facilities for diagnosis, isolation, and treatment of infectious cases are now reasonably adequate.

Aside from the obvious fact that the prevalence of tuberculous infection and disease is extremely high, little is known of the epidemiological aspects of tuberculosis among the native population. Some information regarding tuberculin sensitivity among Alaska natives was obtained during two BCG vaccination programs, one by Aronson in southeastern Alaska in 1938 (1) and the other by the Alaska Department of Health from 1948 to 1951 (2).

Because of the limited information on this subject, it appeared desirable to report the results of a tuberculin survey of the villages along the Yukon River during the spring of 1957.

Both authors are with the Bureau of State Services, Public Health Service. Dr. Comstock is epidemiologist, Tuberculosis Branch, and Miss Porter is chief nurse of the Epidemiology Unit, Arctic Health Research Center, Anchorage, Alaska. (Manuscript received for publication March 10, 1959.)

In addition, the relationship of the size of tuberculin reaction to the prevalence of tuberculosis in this and other populations has important implications for the interpretation of tuberculin sensitivity.

Material and Methods

The original purpose of the tuberculin testing was to obtain baseline data regarding the prevalence of infection prior to the initiation of a controlled trial of isoniazid prophylaxis in the Bethel area of Alaska. This area included the deltas of the Yukon and Kuskokwim Rivers, and is bounded on the west by the Bering Sea, and in the interior by lines from Goodnews Bay and Unalakleet to McGrath (fig. 1). Because the testing teams were available for only a short time before the spring breakup of ice would make travel temporarily impossible, their efforts were concentrated in the villages in the northern half of the area to take advantage of the fact that breakup normally occurs a little later along the Yukon than along the Kuskokwim.

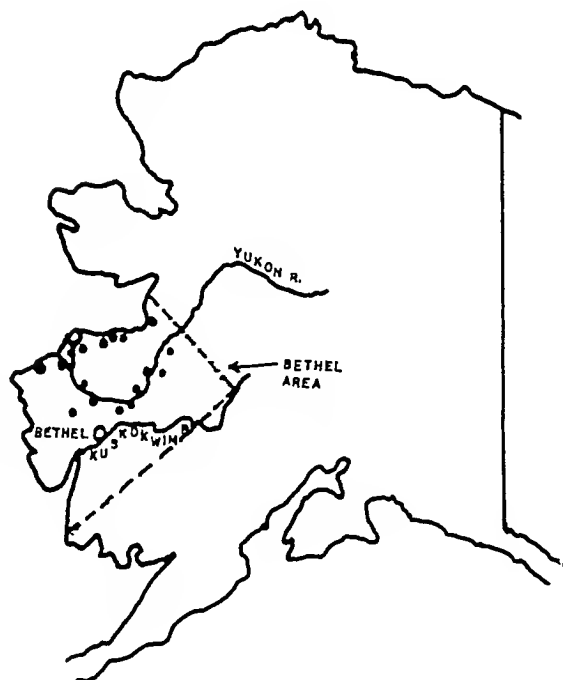

The tests were given and read by three experienced nurses from the tuberculosis program of the Public Health Service, assisted by the

staff of the ambulatory chemotherapy program of the Arctic Health Research Center. All participants were given 5 tuberculin units (T.U.) (0.0001 mg.) of PPD-S. In most instances, the tests were read on the second day; a few readings on the third day have also been included. The transverse diameters of both erythema and induration were carefully measured and recorded to the nearest millimeter.

According to the most recent village rosters, which were brought up to date at the time of the testing, 2,930 persons resided in the 19 villages selected for testing. Tests and readings were completed satisfactorily for 2,285 persons, or 78 percent of the total population, and 91 percent of those at home on the day of the tests (table 1). Many of the remaining 9 percent who did not come in for testing or reading lived far enough from the village centers that they could not come when traveling conditions were poor. The largest group of nonparticipants were those classified as "working or visiting," a large proportion of whom were away on hunting trips. It is likely that many of these persons would have participated if it had been possible to set up a definite schedule in advance of the arrival of the testing teams.

The study population has been restricted to natives of the selected villages with completed tests and identification data. In addition to nonparticipants, 72 whites have been excluded,

Figure 1. Villages participating in the tuberculin testing survey in the Bethel area of Alaska, 1957.

• = PARTICIPATING VILLAGE

as have 2 natives for whom no birth date was available. The study population thus consists of 2,211 persons, 1,777 of whom are classified as Eskimo, 429 Indian, and 5 as mixed Eskimo and Indian. Many of each race have some admixture of white blood.

Table 1. Participation in the tuberculin testing survey among natives of the lower Yukon, 1957

Participation category	Number	Percent
Total population of villages	2,930	100.0
Persons with completed test	2,285	78.0
Persons with no or incompleted test	645	22.0

Results

In order to interpret the results of any tuberculin testing survey, it is necessary to consider the problem of nonspecific tuberculin sensitivity, since it is now clear that the true extent of tuberculous infection in a population can be masked by the coexistence of tuberculin sensitivity resulting from infection with other organisms (3). Some evidence on this point was available prior to the survey.

First, atypical acid-fast organisms classified as photochromogens or nonphotochromogens have not been observed in specimens from patients at the Alaska Native Health Service Hospital in Anchorage, even though

scotochromogens were not uncommon. Although this sort of negative evidence is not conclusive, neither can it be entirely ignored, since it is based on work done by Alice Timpe, Alaska Native Health Service, Anchorage, a bacteriologist experienced in the recognition of atypical acid-fast bacilli (4). It does suggest that presently recognized and naturally occurring sources of nonspecific tuberculin sensitivity are probably not highly prevalent in this population.

We expected to find tuberculin sensitivity resulting from BCG vaccination—in some respects the prototype of nonspecific sensitivity—in this population, since BCG vaccination had been done sporadically since 1949 in the Bethel area. It was therefore necessary to identify as accurately as possible the persons in the study population who had been vaccinated and those who had not. This was accomplished by matching, for the tested villages, the tuberculin test records with the vaccination files of the Alaska Department of Health and the ambulatory chemotherapy program of the Arctic Health Research Center.

It is considered that the identification of those who were vaccinated is quite accurate, but a few persons may have been vaccinated without this fact having been recorded, while others may have been vaccinated in villages not included in the testing program. Consequently, some persons classified in this study as unvaccinated may in fact have been vaccinated. We believe that this is not an appreciable source of error except for those under 10 years of age in 1957.

The choice of antigen used for testing is also related to the subject of nonspecific sensitivity, since some antigens detect nonspecific sensitivity better than others. In this survey, the standard antigen given to everyone in the study population was 5 T.U. of PPD-S. In addition, 301 participants were also given an equivalent dose of a PPD prepared from an organism originally classified as a *Nocardia* but later found by others to resemble a *Mycobacterium* (5, 6). The reactions to this antigen, PPD-C, reflect some types of nonspecific sensitivity much better than do those to PPD-S (7). Among the 301 persons tested with both antigens, 243 showed some induration to one

or both preparations. Sixty persons reacted only to PPD-S; four reacted only to PPD-C. Of the 179 reacting to both, only 1 had a significantly larger reaction to PPD-C than to PPD-S. These findings suggest that the kind of nonspecific sensitivity detectable by PPD-C is uncommon in this population.

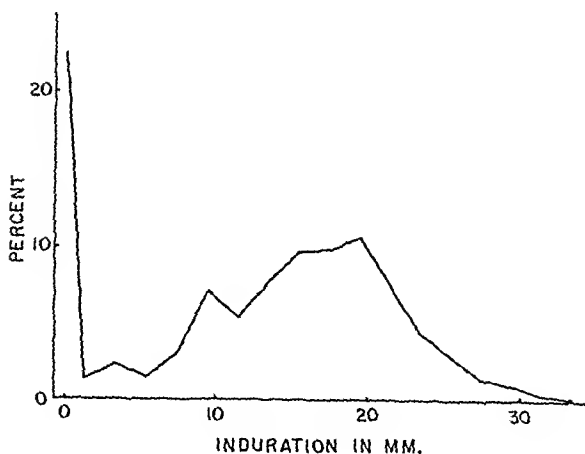

Perhaps the question of whether or not the lower Yukon natives manifest nonspecific sensitivity to the 5-T.U. dose of PPD-S is best answered by the characteristics of the frequency distributions of reaction sizes to this antigen (table 2, fig. 2). The curve of the percentage distribution for the entire study population is bimodal, with 23 percent showing no induration to 5 T.U. of PPD-S. Of those with some induration, there are more persons with very small reactions than with very large reactions. This was noted by each of the three readers and suggests that there is some nonspecific sensitivity in this population, for it seems reasonable to believe that reactions from a single, specific infection would approximate

a normal curve of distribution, and that excess reactions of any size would very likely have been caused by something else.

It has already been mentioned that some non-specific sensitivity resulting from BCG vaccination might be expected in this population. To investigate this possibility, it is first necessary to establish a baseline, which is provided by the distribution of reaction sizes among persons over the age of 15 years who had no history of vaccination (table 2, fig. 3).

Except for a spur at 9-10 mm. of induration (which appears to be the result of terminal digit preference), the distribution closely approximates a normal one, and is consistent with the notion that the tuberculin test is measuring sensitivity to a single specific infection. Indeed, this distribution, with a mean reaction size of 15.9 mm., is almost the same as those found among patients in tuberculosis hospitals (8). Consequently, we have further reason to believe that there is little, if any, non-specific sensitivity among unvaccinated persons in this area of Alaska which can be detected by the 5-T.U. dose of PPD-S.

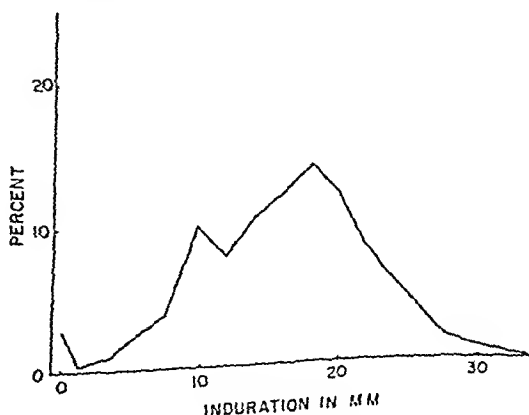

The amount of nonspecific sensitivity resulting from previous BCG vaccination can be estimated from a comparison of the distribution of reaction sizes among vaccinated and unvaccinated persons. Because very few adults had been vaccinated, it is necessary to restrict the comparison to persons under the age of 15 years. Among both groups, the vaccinated and the un-

vaccinated, about 40 percent had no reaction at all to 5 T.U. of PPD-S (table 2, fig. 4). The most apparent difference between the two groups is that 9 percent of the vaccinated had reactions of 1-4 mm. in diameter, whereas only 4 percent of the unvaccinated had reactions of this size. If the comparison is limited to persons with reactions of 5 mm. in diameter or larger, the percentage distributions for the vaccinated and unvaccinated are very similar and do not differ significantly.

Since both distributions are also very similar to that for unvaccinated adults, it seems reasonable to infer that in the lower Yukon area reactions of 5 mm. or larger to the 5-T.U. dose of PPD-S reflect sensitivity resulting from natural infection. For if postvaccinal sensitivity were as strong as that resulting from natural infection, one would not expect to find an excess of very small reactions among the vaccinated without a concomitant excess of larger reactions. The most reasonable explanation of the observed finding is that vaccination in this population resulted in a low level of allergy, and that the spectrum of reactions larger than 5 mm. is probably the result of natural infection which may or may not be superimposed on postvaccinal sensitivity.

That there was in fact a low conversion rate attributable to vaccination is suggested by an examination of the proportion of those with reactions of 5 mm. or more induration among

Figure 3. Distribution of sizes of reactions to 5 T.U. PPD-S among 953 unvaccinated natives, 15 years or older, lower Yukon area, 1957.

the 350 vaccinated persons of all ages. Sixty of these persons had been vaccinated in 1956, or less than 16 months prior to testing (table 3). Only 11, or 18 percent, had reactions of 5 mm. or more in diameter. Although the proportion of reactors increases markedly as the time between vaccination and testing lengthens, this increase is about what would be expected from the natural infection rate in these communities. These findings suggest that either the vaccine used, or the conditions of vaccination, or both, resulted in a very low level of tuberculin sensitivity from vaccination.

Furthermore, aside from the low proportion of small reactions attributable to vaccination, it seems fair to conclude that there is probably no nonspecific sensitivity in this population which can be detected by the 5-T.U. dose of

PPD-S. Consequently, estimates of the prevalence of tuberculous infection will not be very far wrong if they are based on reactions of 5 mm. or more in diameter. Smaller reactions may be either the result of vaccination or the "left hand tail" of the distribution of reactions from specific infection. In some respects this is a most fortunate circumstance, for had BCG vaccination been as effective in causing tuberculin conversions in this population as it has been reported to be in other vaccinated groups, the interpretation of tuberculin sensitivity would have been made much more difficult, and in some respects, impossible.

The prevalence of tuberculous infection in the study population may now be considered, defining a reactor as anyone with 5 mm. or more of induration. Females had slightly

larger tuberculin reactions on the average than males. There were no significant differences between Eskimos and Indians, a finding in apparent disagreement with that reported by Weiss (2), who found somewhat lower reactor rates among interior Indians than among Eskimos of the Yukon and Kuskokwim deltas. However, his populations were drawn from a larger area than that of this study.

There were tremendous differences in tuberculin sensitivity with age (table 4, fig. 5). The prevalence of reactors was 22 percent in the age group 0-4 years, and it increased rapidly

up to the age group 15-19 years, which had a prevalence of 96 percent. This high level was maintained to 65 years, with a moderate decrease among older persons. Among persons with a history of vaccination, except in the youngest age group where the prevalence among the vaccinated was slightly but not significantly higher, the prevalence of positive reactions was generally lower than among persons classified as unvaccinated. At first glance, this seems to be a disturbing finding. But when it is recalled that the vaccinated had been previously selected as negative reactors, that vaccination appears to have caused relatively little sensitivity, and that the subjects were presumably exposed thereafter to a very high natural infection rate, the differences between the vaccinated and the unvaccinated in this respect appear more reasonable.

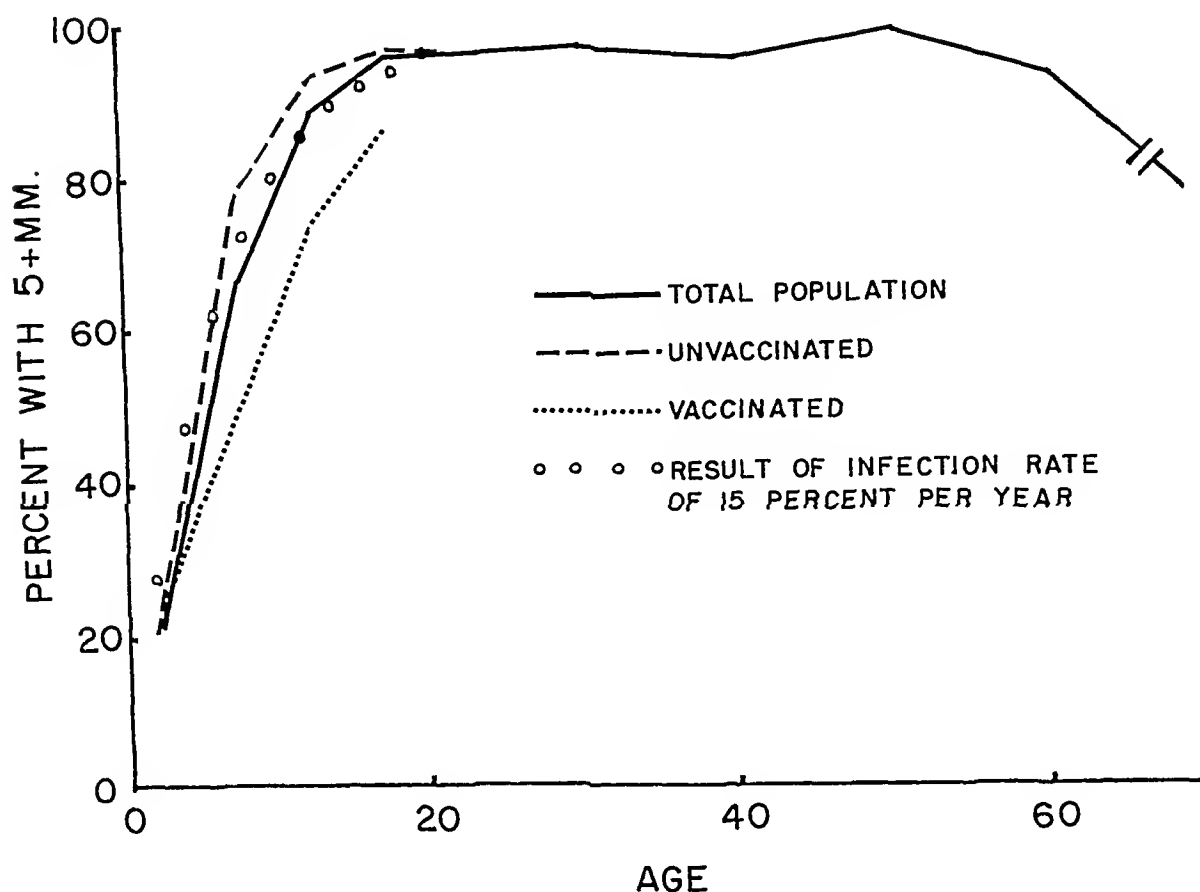

Because of vaccination, even though its effects were not great, it is impossible to ascertain with certainty the infection rate that has prevailed among this population in recent years. However, it can be shown that a prevalence ratio of 96 percent at age 20 can only be achieved by an average infection rate of 15 percent per year. The prevalence resulting from this theoretical rate is indicated by open circles in figure 5. Vaccination cannot affect this average rate since practically no one older than 20 years had been vaccinated.

The average infection rate experienced by

Figure 5. Natives with reactions of 5 mm. or more to 5 T.U. PPD-S, by age and vaccination status, lower Yukon area, 1957.

younger persons is more problematical. If one accepts that vaccination in this particular instance did not appreciably affect the proportion of persons with reactions of 5 mm. or more in diameter, it would be reasonable to utilize the experience of the total group as reflecting the prevalence of tuberculous infection at various ages.

In any event, since an average annual infection rate of 15 percent would produce the observed prevalence at age 20, and since the points on the observed curves fall progressively below the theoretical ratio as age decreases below 20 years, it seems likely that the infection rate 20 years ago was appreciably higher than 15 percent, and that more recently it has fallen to a much lower level, possibly in the neighborhood of 5 percent per year. This is still a much greater infection rate than that reported for the United States as a whole, which has been esti-

mated to be about 0.1 percent per year at the present time (9).

The definition of a positive reactor accepted in the preceding sections was an arbitrary one, based partly on the fact that the 5-mm. level of reaction excluded the most noticeable effects of vaccination, and partly on common usage. However, for some time the wisdom of using the same definition of a positive reactor in all areas has been questioned. In areas where non-specific sensitivity is very common, defining positive reactors as those persons with 5 mm. or more of induration to the 5-T.U. dose may classify so many persons with false positive (nonspecific) reactions among the positive group that the separation of true positives from true negatives is very unsatisfactory. On the other hand, in areas where there is little or no nonspecific sensitivity, the same definition of positive reactors may yield a relatively pure

group of truly infected persons, but the group classified as negative may also include a number of infected persons. Some evidence that this does, in fact, occur may be gathered from comparing the frequency of tuberculous disease among persons with different sizes of tuberculin reactions in two geographic areas.

The experience of Muscogee County, Ga., and Russell County, Ala., where there appears to be a great deal of nonspecific sensitivity to the 5-T.U. dose may be contrasted with that of the lower Yukon area where there appears to be very little. In the spring of 1950 a tuberculin testing and chest X-ray survey was conducted in Muscogee and Russell Counties, in which the participants received 5 T.U. of PPD (RT XIX-XXI, supplied by the State Serum Institute, Copenhagen, Denmark).

All persons classified as having suspected or definite tuberculosis on the basis of the survey followup examination had their records and films reviewed after 6 years of observation. The followup examinations were quite extensive for most of them, but for a few they consisted only of a single, large chest film. On the basis of the available evidence—extensive or scanty—but without consideration of the

tuberculin sensitivity of the subjects at the time of the survey, a decision was made as to whether or not the findings appeared to have warranted classifying persons as tuberculous or suspected of having tuberculosis. Persons so classified on the basis of this retrospective review are counted as cases in the present analysis.

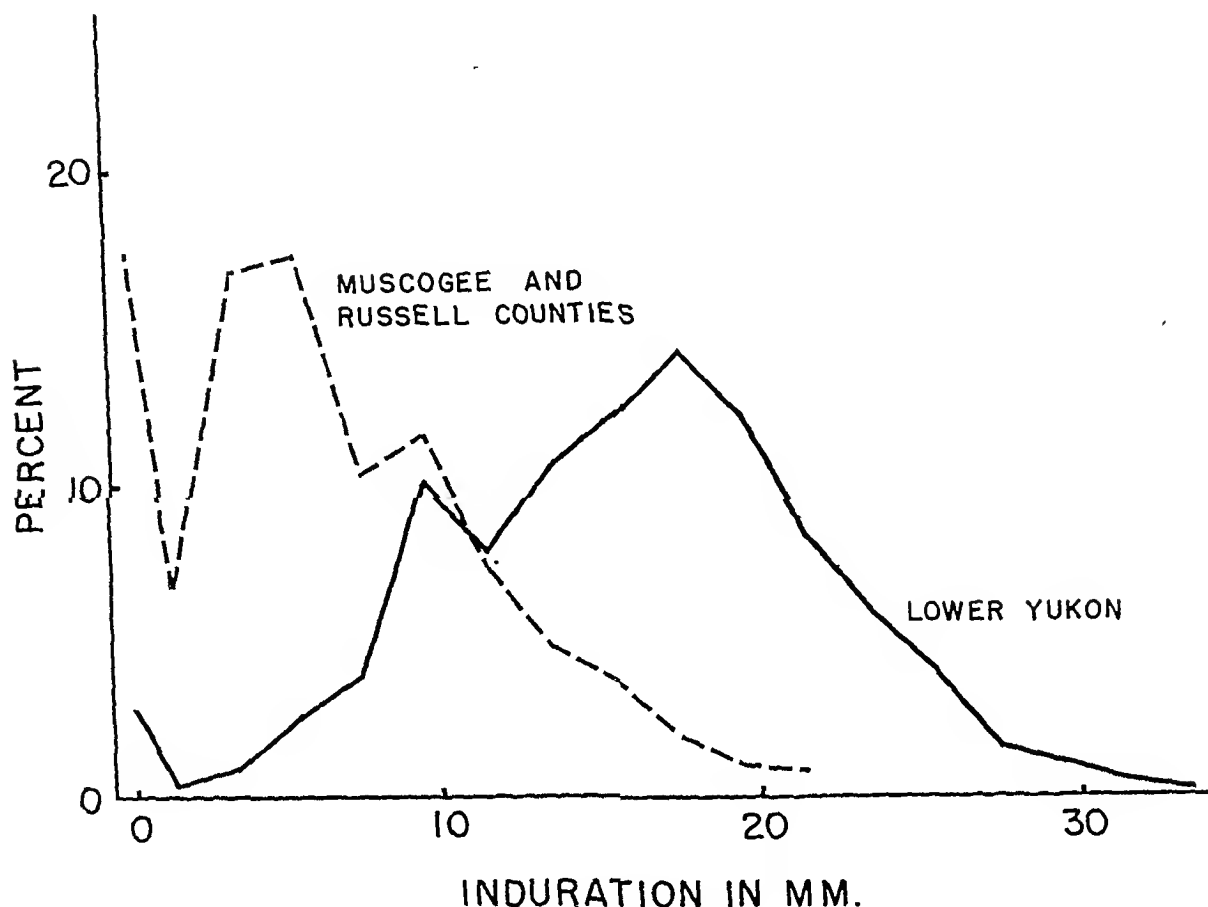

For the participants in the tuberculin testing survey along the lower Yukon, the records from the X-ray survey of the villages during the preceding year were matched against the tuberculin test cards. For those who had been tested and X-rayed, the diagnosis made by the Alaska Department of Health was utilized to define a case, accepting as such all those classified as having suspected or definite reinfection-type tuberculosis. As in the Muscogee-Russell area, this diagnosis in some instances was based on a single film; in others, it was substantiated by a long period of followup examinations, including bacteriological and clinical studies. The clinical diagnosis was independent of the tuberculin findings of the survey.

In both areas, the great majority of cases appeared to be inactive at the time of the X-ray survey. However, 24 percent of the cases in the lower Yukon area and 18 percent

Figure 6. Comparison of distributions of sizes of reactions to 5 T.U. PPD among unvaccinated persons 15 years or older in two geographic areas.

of those in the Muscogee-Russell area have had positive bacteriological findings at some time.

There is a marked difference between the two populations in the distribution of reaction sizes to 5 T.U. of PPD in unvaccinated persons over 15 years of age (table 5, fig. 6). Half of the reactions in the Muscogee-Russell area are smaller than 7 mm.; in contrast, half of the reactions in the lower Yukon area are larger than 16 mm. On the basis of unpublished studies in Muscogee and Russell Counties and studies by Nissen Meyer (10), only a small part of this difference can be attributed to differences in the antigens used in the two areas.

Before examining the relationship of tuberculous disease to the size of tuberculin reaction, one more difficulty must be considered. It is well known that there are definite reader differ-

ences which may enter into the problem of interpreting tuberculin sensitivity. Although several different readers participated in the Muscogee-Russell survey, it was possible to have each reader measure reactions from all major segments of the population. In the lower Yukon area, this could not be done. One reader, for instance, worked in the villages near the mouth of the Yukon; the other two farther up the river and in Unalakleet. The readings by the first reader formed a distribution about 3 mm. smaller on the average than the readings of the other two nurses. This difference appeared to have been a personal one—it did not appear to be associated with village, race, sex, age, or vaccination status—and is consistent with differences noted in the readings of these three nurses on other series of comparative readings.

group of truly infected persons, but the group classified as negative may also include a number of infected persons. Some evidence that this does, in fact, occur may be gathered from comparing the frequency of tuberculous disease among persons with different sizes of tuberculin reactions in two geographic areas.

The experience of Muscogee County, Ga., and Russell County, Ala., where there appears to be a great deal of nonspecific sensitivity to the 5-T.U. dose may be contrasted with that of the lower Yukon area where there appears to be very little. In the spring of 1950 a tuberculin testing and chest X-ray survey was conducted in Muscogee and Russell Counties, in which the participants received 5 T.U. of PPD (RT XIX-XXI, supplied by the State Serum Institute, Copenhagen, Denmark).

All persons classified as having suspected or definite tuberculosis on the basis of the survey followup examination had their records and films reviewed after 6 years of observation. The followup examinations were quite extensive for most of them, but for a few they consisted only of a single, large chest film. On the basis of the available evidence—extensive or scanty—but without consideration of the

tuberculin sensitivity of the subjects at the time of the survey, a decision was made as to whether or not the findings appeared to have warranted classifying persons as tuberculous or suspected of having tuberculosis. Persons so classified on the basis of this retrospective review are counted as cases in the present analysis.

For the participants in the tuberculin testing survey along the lower Yukon, the records from the X-ray survey of the villages during the preceding year were matched against the tuberculin test cards. For those who had been tested and X-rayed, the diagnosis made by the Alaska Department of Health was utilized to define a case, accepting as such all those classified as having suspected or definite reinfection-type tuberculosis. As in the Muscogee-Russell area, this diagnosis in some instances was based on a single film; in others, it was substantiated by a long period of followup examinations, including bacteriological and clinical studies. The clinical diagnosis was independent of the tuberculin findings of the survey.

In both areas, the great majority of cases appeared to be inactive at the time of the X-ray survey. However, 24 percent of the cases in the lower Yukon area and 18 percent

was very different in the two areas, being nearly 30 percent in the lower Yukon area and only 1.2 percent in Muscogee and Russell Counties (table 6, fig. 7). In the lower Yukon area, there was no significant difference in the frequency of tuberculosis among persons with different sizes of tuberculin reactions, whereas in Muscogee and Russell Counties, there was a marked and progressive increase in the frequency of tuberculosis with increasing size of the tuberculin reaction. The same relationships were noted when the cases were restricted to bacteriologically confirmed cases from the two areas.

Previous reports have noted that there is a positive correlation between size of tuberculin reaction and subsequent incidence of tuberculosis, similar to that noted for prevalence of tuberculosis in the Muscogee-Russell area (11-14). For such a relationship, there could be at least two explanations. One is based on the notion that allergy to tuberculoprotein is harmful to the host, and that demonstrable disease is therefore more likely to be present among those with the highest levels of allergy. The second is that among persons with small reactions, there are many in some areas who are not infected with tubercle bacilli but with something else much less pathogenic, while persons with large reactions have almost all been infected with tubercle bacilli.

Either hypothesis is consistent with the findings from Muscogee and Russell Counties, and with the reports on incidence of tuberculosis according to the size of tuberculin reactions. However, the first hypothesis does not fit with the findings from the lower Yukon area; the second is entirely consistent. These findings therefore indicate that the degree of allergy per se does not appear to be related to the likelihood of having tuberculous disease, and provide additional support for the concept of non-specific sensitivity (15-17).

Discussion

Those who are unfamiliar with the tuberculosis situation among Alaska natives may have difficulty in accepting that almost 30 percent of the adults in these 19 villages had X-ray findings compatible with past or present tu-

berculosis. However, there is evidence that this extraordinary prevalence of tuberculosis is not exaggerated. Historical records suggest that the arrival of the white man in Alaska was closely followed by the appearance of tuberculosis among the natives (18). This soon assumed the characteristics of an epidemic, which only in recent years has appeared to be subsiding. Prior to 1952, the recorded tuberculosis mortality for Alaska natives was well in excess of 500 per 100,000 (19,20); for the years 1953-56, the average annual death rate for the Bethel area was 282, according to unpublished data from the Arctic Health Research Center. Also consistent with the epidemic character of tuberculosis in this population is the prevalence of tuberculin sensitivity, which is as high, if not higher, than any recorded in recent years. In the International Tuberculosis Campaign, only a few cities in Poland, Yugoslavia, and North Africa had reactor rates approaching those among natives of the lower Yukon (21).

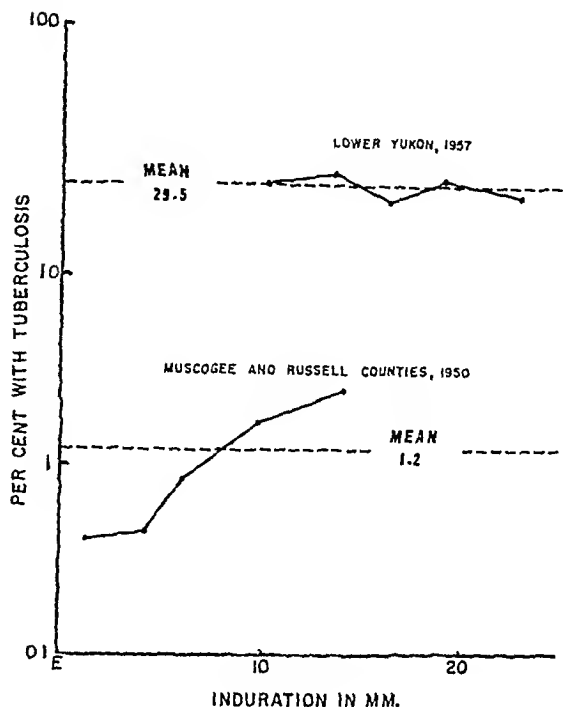

In an area where tuberculosis is so common, it might be suspected that most pulmonary abnormalities would be classified as tuberculous. However, an independent reading of several hundred films from the Bethel area by Comstock yielded prevalence rates essentially the same as those derived from film readings by the Alaska Department of Health. In addition, similar findings have been noted in the Eskimo population of Greenland. Helms (22) reported that 41 percent of the adults in Angmagssalik during the period 1948-51 showed some X-ray evidence of pulmonary tuberculosis; and in 1956, Stein and Groth-Petersen (23), in a very thorough survey of the native Greenlanders, found that 29 percent of those over 15 years of age showed lung changes of a tuberculous character. On the basis of the available evidence, it is our opinion that the reported prevalence of tuberculous lesions in the present study population is entirely reasonable.

Confidence in the lack of an association between the size of the tuberculin reaction and X-ray evidence of reinfection-type tuberculosis in this study population is strengthened by the fact that the same relationship was observed when the cases were restricted to persons with a history of positive bacteriological findings.

Such reader differences would not have been of critical importance except that the prevalence of tuberculosis was appreciably higher in the villages near the mouth of the Yukon, those tested by the first reader, than among the villages tested by the other two. Such a situation obviously tends to produce a "built-in" correlation between smaller reactions and increased prevalence of tuberculosis. However, when each reader's subjects were studied separately, the relationships between reaction size and frequency of tuberculosis were similar for each of the three groups.

It therefore appeared reasonable to combine the results for all three readers, but only if this could be done in such a way that the "built-in" correlation could be avoided. First, to eliminate the possible effects of vaccination, the subjects in both areas were restricted to unvaccinated persons over the age of 15 years. Then, for each reader in the lower Yukon survey, the subjects who showed some reaction (erythema or any induration) to the 5-T.U. dose were ranked by size of reaction, and each of the three groups was divided into fifths or quintiles. The quintiles from each reader's subjects with the smallest reactions were combined to form the first quintile of the total group, those with the next larger reactions were combined to form the second quintile, and so on. The subjects from the Muscogee-Russell area with some reaction to 5 T.U. of PPD were also divided into quintiles. In both areas, the populations were divided in such a way that each quintile would

Figure 7. Prevalence of reinfection-type pulmonary tuberculosis among unvaccinated reactors 15 years of age or older in two geographic areas, by size of reaction to 5 T.U. PPD.

contain a whole number of persons; the cases were allocated on a proportionate basis which resulted in fractional numbers of cases being assigned to each quintile.

The total prevalence of tuberculosis among adults with some reaction to the 5-T.U. dose

Table 6. Prevalence of reinfection-type pulmonary tuberculosis among unvaccinated reactors,¹ 15 years of age or older in two geographic areas, by size of reaction to 5 T.U. PPD

Quintile	Lower Yukon				Muscogee and Russell Counties

¹ Defined as all persons with some erythema or induration to the 5-T.U. dose of PPD.

tions increased markedly with age, reaching a level of 96 percent in the age group 15 to 19 years. This represents an average infection rate of 15 percent per year. It appears that the infection rate was even higher 20 years ago, and appreciably lower in recent years.

Among unvaccinated adult reactors to the 5-T.U. dose, the prevalence of active and inactive reinfection-type tuberculosis was almost 30 percent, and was essentially the same among persons with small and large tuberculin reactions. In contrast, in Muscogee County, Ga., and Russell County, Ala., where there is a great deal of nonspecific sensitivity, the prevalence among unvaccinated adult reactors was 1.2 percent, and was much higher among persons with large reactions than among those with small reactions. This finding is interpreted to signify that the prevalence of tuberculosis does not vary with the degree of allergy from specific infection, and as being consistent with the concept that there is considerable nonspecific tuberculin sensitivity in the Muscogee-Russell area and little if any in the lower Yukon area.

The problem of defining a positive tuberculin reactor is discussed, and it is suggested that the definition selected should vary according to the prevalence of nonspecific sensitivity in the area under consideration.

In addition, a similar relationship was also noted for pulmonary calcifications which, with the virtual absence of histoplasmin sensitivity in this population (24), are likely to represent the residuals of healed primary tuberculosis.

The comparison between the findings in the lower Yukon area and those in two counties in the southeastern United States clearly illustrate the difficulties imposed on the interpretation of tuberculin sensitivity when this is attempted on the basis of a single standard for negative and positive reactions regardless of the prevalence of nonspecific sensitivity. In populations similar to the unvaccinated adult natives of the lower Yukon area, if the findings of this study can be confirmed by further investigation, it may be that any reaction to 5 T.U. of PPD-S can be considered as positive for tuberculous infection.

On the other hand, in areas like Muscogee and Russell Counties, where nonspecific sensitivity is very common, a simple dichotomy of reactions into negative and positive can never be entirely satisfactory. If the dividing line is placed fairly low on the scale of tuberculin sensitivity, say between 4 and 5 mm. of induration to the 5-T.U. dose, the negative group will contain relatively few persons infected with tubercle bacilli, but those classified as positive will include many who are infected with something else. Shifting the dividing line to 15 mm. would probably reduce the false positives to a negligible proportion, but would result in classifying many persons infected with tubercle bacilli among the negatives.

For those areas where nonspecific sensitivity is commonly encountered, a further subdivision into more categories than the two of negative and positive in common usage should be seriously considered. At the very least, it would seem wise to interpose an additional category of "doubtful" for those persons with intermediate-sized reactions of 6 to 10 mm. to the 5-T.U. dose. With such a classification, the negative reactions of 0 to 5 mm. would very largely signify the absence of tuberculous infection, and the positive reactions of 11 mm. or more of induration would very largely signify that tuberculous infection had occurred. Reactions of 6 to 10 mm. would quite properly be labeled doubtful, since in areas with more than

one cause for tuberculin sensitivity, testing with the 5-T.U. dose of PPD-S alone cannot differentiate specific reactions of this size from non-specific reactions.

The present study is only a small contribution to a long series initiated by Palmer and his associates to apply the concepts of the normal distribution of attributes in biological populations to the problem of tuberculin sensitivity in humans from many geographic areas (15-17, 25). By using standardized antigens and careful techniques of measurement, it has been possible to show that the varied patterns of sensitivity elicited in different populations can only be explained satisfactorily by the existence of tuberculin sensitivity caused by something other than the tubercle bacillus. Although this concept has shattered the apparent simplicity of the tuberculin test as a casefinding and diagnostic tool, its application to the practical uses of tuberculin testing will result in the resolution of some of the former enigmas of tuberculin sensitivity and in a more accurate subdivision of tested populations into those who are truly infected with tubercle bacilli and those who are not.

The ability to make this subdivision with as much discrimination as possible is becoming progressively more important. For as tuberculosis declines in many areas to the point where it may be controlled, the seedbed of disease will more and more come to be those who have been infected in the distant past. These must be identified as accurately as possible if maximum progress is to be maintained toward the eradication of tuberculosis.

Summary

In 1957, tuberculin tests were given to 2,211 natives living in 19 villages along or near the lower Yukon River in Alaska. The test antigen was 5 T.U. of PPD-S, and all reactions were carefully measured by experienced nurse readers. Consideration of the distributions of reaction sizes suggests that there is little nonspecific tuberculin sensitivity detectable by this dose of tuberculin in this native population, except for some sensitivity attributable to BCG vaccination.

The prevalence of positive tuberculin reac-

*Excerpts from a discussion of facts, fancy, and corruption
in the interpretation of science to the public.*

Quackery and the News

WALLACE F. JANSSEN

IN the past half century, there has been a profound change in the attitude of the press, and the lay public, concerning the news of science. Editors were inclined at one time to regard the scientist as a long-haired character, a sort of modern Merlin muttering mathematical incantations over his test tubes. Today the scientist is a respected source of important news. With this has come a tremendous increase in the amount of information about science which is reaching the public.

A study on "Science, the News, and the Public," made for the National Association of Science Writers, revealed that Americans get their science news primarily from newspapers, with television and magazines ranking close together as the next most popular sources.

In 10 major categories, medical news was third in reader popularity, outranking even such topics as sports, comics, and crime. Thirty-seven percent of the newspaper readers reported that they read all the health news they can find, as compared with 28 percent who read the nonmedical science news.

Not only has there been a great increase in

the volume of medical news but it seems entirely likely that this situation will continue.

Is this good? Or is it a Frankenstein monster that we must tame, control, or learn to live with?

Certainly the dissemination of knowledge is good. Undeniably, however, lay press reporting of news on health and medicine has had some undesirable characteristics and side effects as well as good effects.

The years since World War II have seen unprecedented progress in the development of new drugs. Antibiotics, for example, have revolutionized the treatment of infectious diseases and all but wiped out some of them. But we have seen how the publicizing of these miracle drugs has in some instances led to excessive and indiscriminate use with harmful consequences. Patients and their relatives beg physicians to use this or that product. Fads and fashions in the use of newly popular preparations are familiar to the medical profession.

A standard pattern has been observed in the life history of highly publicized drugs. First is the period of "great expectations." Often this begins before the drug is on the market. Stories appear reporting that some researcher has hit on a promising new compound that may be of value in treating some more or less common affliction. For many writers these are bread-and-butter pieces—a standard item of journalistic merchandise. A series may be published on developments in a research program. Finally the great day comes when the

Mr. Janssen, director, Division of Public Information, Food and Drug Administration, U.S. Department of Health, Education, and Welfare, delivered the Williams Memorial Lecture in the 24th annual series, "Lectures to the Laity," at the New York Academy of Medicine, November 1958. Full text of the series, entitled "Science, Man's Master or Servant," will be published by the academy.

Radioactivity Levels in Milk Samples

The levels of radioactivity in milk collected during February 1959 from 10 sampling stations across the country remained below the levels currently suggested as permissible by the National Committee on Radiation Protection and Measurements.

The milk sampling network of stations is part of the program of the Public Health Service for measurement of radioactivity in air, water, and food. In reporting on radioactivity levels in milk, the Service will continue to make comparisons with the permissible levels of the national committee.

The only levels thus far developed for radiation exposure for the general population are those recommended by that committee and the International Commission on Radiological Protection. Both bodies recognize that the general population should be considered separately from industrial workers

exposed to radioactivity. The national committee has recently revised its 1953 recommendations for industrial workers, but left those for the general population unchanged. The international commission has made recommendations regarding radiation exposure for the general population which are being studied by the national committee.

The national committee, in a statement of April 23, 1959, considers "that undue risks to the population will not be incurred by following current policies for a while longer, during which time it is hoped that methods may be established for a meaningful analysis and control of population exposure."

Both the monthly levels and the yearly averages for all radioactivity in milk samples remained below permissible levels suggested by the national committee.

Yearly average levels ¹ of radioactivity in milk samples, period ending February 1959

10,000 patients taking his treatment, a statement the Food and Drug Administration did not think exaggerated.

Mr. Hoxsey called his medicine "chemotherapy." It cost \$400 plus \$60 of incidental expenses. The American Medical Association called it a cough sirup. It might also be called a mild laxative, since it contains cascara sagrada along with such other ingredients as prickly ash bark, burdock, poke root, and extract of red clover blossoms.

The promotion of the Hoxsey treatment is a classic illustration of how unfortunate people may be misinformed regarding a life-or-death problem—the treatment of cancer. It is the more significant in view of its success at a time when millions of dollars and the best efforts of health educators were being devoted to providing correct and reliable information on the treatment of cancer, and to urge early treatment.

A variety of methods were used and to some extent are still being used to promote the Hoxsey treatment. One of these was the purchase of editorial space in nationally circulated magazines. The late Rev. Gerald K. Winrod, of Wichita, Kans., was paid \$82,000 for promoting the treatment in his *Defender* magazine. This circulated mainly to Protestant fundamentalist groups in rural sections and small towns. A newsstand publication called *Man's Magazine* was paid for printing illustrated articles composed largely of testimonials. These were the same ones which Hoxsey has been using for years and which were investigated by the Food and Drug Administration and exposed in open court. Millions of reprints of these articles were used by Hoxsey for promotion purposes. The *National Christian Crusader*, published by Rev. Dr. Merle E. Parker of Santa Ysabel, Calif., devoted its columns to attacking the Food and Drug Administration and the medical trust, and boosting the Hoxsey treatment. Circulation of the *Crusader* was reported to exceed 1 million copies. These were not all of the periodicals which promoted the Hoxsey cure in their editorial columns.

Most of the pro-Hoxsey publicity was obtained after the issuance of the first injunction against the treatment in 1952. The publishers cooperated notwithstanding a decision of the

U.S. Court of Appeals holding that the medicine had been proved worthless for the treatment of cancer. Some of the articles, in fact, reported the Government's efforts to stop the sale of the medicine and described it as "controversial," a word which to some editors and broadcasters seems to justify copy they would not otherwise tolerate.

Is it possible, when a medical myth has been widely disseminated, to mount a successful counterattack? Many are skeptical about this, including some public health authorities. They have the idea that any publicity about a worthless remedy will only serve to advertise it.

In April 1956, when it was clear that litigation to stop distribution of the Hoxsey treatment might be prolonged for years, a nationwide public warning was issued under authority of section 705 of the Federal Food, Drug, and Cosmetic Act. It was widely published by the press, and although some papers devoted as much space to printing Mr. Hoxsey's protests and denunciations as they did to the Government's warning, the warning was effective. There was an immediate and drastic reduction in patronage of the clinics, both at Dallas, Tex., and Portage, Pa. By a conservative estimate, in the first 30 weeks after the warning was issued, at least 3,000 people had been dissuaded from being taken in by the false promise of a quick and painless cure, without recourse to methods that could really have helped them.

Especially effective was a condensed version of the warning sent to farm, lodge, and church periodicals. These reached older people and residents of rural areas, groups most exposed to the Hoxsey publicity. Some editors of these papers received numerous abusive letters from pro-Hoxsey readers. Not one of these editors retracted what they published. Several of them commented to us that the need for information was indeed serious, in view of the number of people who apparently believed in the treatment.

As any editor can tell you, a correction of a story will not reach exactly the same people who read the original incorrect story. Similarly, more publicity is needed to offset a medical lie than to spread it in the first instance. In January 1957, the public warning was reissued,

The Health of Science

In certain areas of science, where empirical data are still hazy, a point of view may acquire a kind of cult following and harden into rigid dogma. Modifications of Einstein's theory, for example, sometimes meet a resistance similar to that which met the original theory. And no doubt the reader will have at least one acquaintance for whom a particular brand of psychoanalysis has become virtually a religion, and who waxes highly indignant if its postulates are questioned by adherents of a rival brand.

Actually, a certain degree of dogma—of pig-headed orthodoxy—is both necessary and desirable for the health of science. It forces the scientist with a novel view to mass considerable evidence before his theory can be seriously entertained. If this sit-

uation did not exist, science would be reduced to shambles by having to examine every new-fangled notion that came along. Clearly, working scientists have more important tasks. If someone announces that the moon is made of green cheese, the professional astronomer cannot be expected to climb down from his telescope and write a detailed refutation. "A fairly complete textbook of physics would be only part of the answer to Velikovsky," writes Prof. Laurence J. Lafleur, in his excellent article on "Cranks and Scientists" (*Scientific Monthly*, November 1951), "and it is therefore not surprising that the scientist does not find the undertaking worthwhile."—*Excerpt from "Fads & Fallacies in the Name of Science" by Martin Gardner.*

new product goes on the market. But this does not end the process of publicity. Other newsworthy developments occur and are reported, including sometimes the discovery of unforeseen and unfortunate adverse reactions. This results in a second standard type of story, warning about the consequences that may result from improper use of a well-known and highly touted preparation.

Up to this point we have been talking about the interpretation of science via the major channels of public information, the wire services, newspapers, magazines, radio, and television. Much of their medical and health news comes from professional sources, research workers, clinicians, and the public relations people associated with the sponsoring organizations.

An increasing proportion of such news is being reported by science writers, men and women who are specializing in this field of reporting. They have an association, the National Association of Science Writers, now 25 years old.

There is no very precise definition of a science writer, but one distinction is that a growing number observe the practice of checking stories with their sources. To many general news reporters this is anathema, censorship, but the

science writer finds that it often helps to improve his story as well as to insure the confidence of his sources. There has been a marked improvement in the quality of science reporting, and this trend continues.

But there are other sources and channels of information on health, medicine, and science. And there are many who interpret science to the public. We need to be at least as much concerned about the misinterpretation of science to the public as we are about its interpretation. Pseudoscience and quackery, as well as legitimate news of science, find their way into the media of communication.

Of course, quackery is nothing new. Surprisingly, however, in this day when so much good information is available, quackery seems to be growing. More and more, people believe in miracles, not only the real miracles of scientific achievement but also the fake miracles of promoters and charlatans.

Quackery Is Big Business

Quackery in the United States is big business. The medical director of the Hoxsey cancer clinic testified he had personally seen 6,000 patients in 2 years. In his book "You Don't Have to Die," Harry M. Hoxsey said he had

East of the Elbe

IN ADDITION to literature covered by *Excerpta Medica*, by the Russian Translation Service sponsored by the Public Health Service, or by private enterprise, a number of medical publications issued in Communist territories are the subject of notes, abstracts, or full translations which appear twice a month in *Scientific Information Report* (mimeographed), sold by the Office of Technical Services, U.S. Department of Commerce, for \$2.75 a copy or \$28 a year.

In keeping with the intent of Congress, these translation services aim not to distribute information directly to a large audience but to provide librarians, editors, reporters, and scientific investigators with access to original materials, if desired.

The following selections from the medical literature which is covered in the *Scientific Information Report* from July 25, 1958, through January 23, 1959, are intended only to suggest the kind of public health information that may be found. They are merely a sample of a sample.

There is no intent to evaluate the significance or validity of the items mentioned.

In the following paragraphs, reference to specific documents is given as follows: the name of the senior author, the publication number of the *Scientific Information Report*, and the document number. All issues of the report are designated by the code number PB 131891-T. The reference (*Frucht 14, 79*) would therefore refer to PB 131891-T14; item 79, a translation from *Das Deutsche Gesundheitswesen*.

Service Statistics

Goals of the Sanitary Epidemiological Service for 1959-65 were reported to the All Union Scientific Society for Hygienists, in Mos-

cow, February 21, 1958. Objectives include 1 epidemiologist per 25,000, 1 sanitary physician per 40,000, 1 industrial sanitarian per 14,000 workers, 1 school sanitarian per 12,000 urban students, and 1 physician bacteriologist per 35,000 (*Lebedev 5, 94*).

Long-range public health plans for Kazakh S.S.R. call for 24,800 more medical personnel by 1965, a 13-percent increase. It is hoped to double the number of health officers: at present, there is 1 for every 70,000 people. This report contains considerable data on hospitals and medical facilities (*Lobova 2, 77*).

Morbidity

The first all-Russian conference of epidemiologists, microbiologists, and infectionists was held in Moscow in 1957. The 400 delegates and guests approved establishment of an all-Russian scientific medical society for the professions represented.

Nikolayeva, R.S.F.S.R. Deputy Minister of Health, reported complete eradication in the Russian Soviet Federated Socialist Republic of plague, cholera, typhus, smallpox, and other infectious diseases. She said that mass outbreaks of typhoid fever and malaria had ceased. The major concerns she reported were influenza, tickborne encephalitis, poliomyelitis, epidemic hepatitis, and prevention of dysentery, typhus, and diphtheria.

Professor Boldyrev stressed the need to improve sanitary conditions, to improve cultural levels, and to sharpen differential diagnosis of enteric diseases in a program to reduce enteric infections. Reports by Smorodintsev, Tokarevich, and Bunin dealt respectively with virology, rickettsioses, and clinical management of dysentery (*Belikov 7, 87*).

Uzbekistan now boasts 188 sanitary-epidemiological stations, 160 bacteriological labora-

this time as a handbill for display in U.S. post offices, hospitals, and other public buildings. This poster was possibly the most effective educational medium of all.

Quackery in Nutrition

The most widespread quackery in the United States today is in the field of nutrition. The American Medical Association says it is costing some 10 million Americans \$500 million each year. This racket is based on misstatement of the facts of the science of nutrition.

More people seem to believe more bunk about food and nutrition than about any other single topic in the health field—and perhaps any other field. It is this widespread dissemination, and the zealous faith of believers in nutrition nonsense, that make it difficult to combat. Food faddism today has aspects of an organized movement that is self-supporting and actively seeking new converts.

The nature of this racket, and the false concepts which promote it, can be learned from the court actions brought by the Food and Drug Administration. The oldtime patent medicine man is back again—but this time he is a “nutrition educator” who rings your doorbell and tries to persuade you that a shotgun mixture of vitamins and minerals, plus some secret factor which nutrition scientists have not yet identified, is the answer to all your health problems.

Vitamin products have a recognized place in modern preventive medicine, but they are not cure-alls, and it is dangerous for anyone to assume that such products can be relied on to treat unidentified ailments. The price charged for only one package of some of these products is enough to pay for several visits to a doctor.

Numerous self-styled “authorities” on nutrition write books and articles, lecture, and sometimes even teach in our colleges. Some of them have no training whatever in nutrition science. A number of so-called “health food lecturers” have been the target of court actions brought by the Food and Drug Administration. One of them recently completed a 1-year prison term. He was convicted on misbranding charges, resulting from claims that his peppermint tea, vegetable soup mix, and wheat germ oil would restore sexual power and cure such conditions as arthritis, cancer, and diabetes.

Recent court actions under the Federal Food, Drug, and Cosmetic Act include these cases:

Capsules of unsaturated fatty acid from safflower oil with vitamin B. This was recommended by a health food store for preventing and treating practically all heart ailments, obesity, and glandular disorders.

Liquid unsaturated fatty acid from safflower oil with vitamin E, represented as effective for maintaining low blood cholesterol levels and overcoming heart disease.

Lecithin, falsely represented as a cure for hardening of the arteries, high blood pressure, coronary thrombosis, diabetes, prostate trouble, and other conditions.

An especially disturbing feature of food faddism is persistent emphasis on the theme that the American food supply, unmatched in quality throughout the world, is deficient, over-processed, or poisoned by fertilizers, pesticides, and food additives. There are indeed serious new problems of food protection brought about by changing technology that are under constant study, but nothing to warrant the grossly irresponsible and inaccurate statements which have appeared in some faddist books and sensational magazines.

Effective Counteraction

Broadly speaking, effective counteraction against faddism and quackery requires the interest and cooperation of all organizations and agencies concerned with the problem, private and public, lay and professional, local, State, and national. This is particularly the case in the field of information and education. I am glad to say that there is already a great deal of such cooperation.

The Commissioner of Food and Drugs recently pointed out that the public has always had difficulty in distinguishing the orthodox from the unorthodox remedy or practitioner, but that “science today has given us the means of distinguishing with considerable certainty the effective from the ineffective. Likewise our laws, based upon medical knowledge, distinguish between what is legal and what is illegal.” More should be done in explaining these distinctions to the public, as well as applying them in law enforcement.

adolescents, 57; nutrition and food sanitation ("the rational use of food for separate groups of the population and the prophylaxis of alimentary diseases"), 55; the hygienic basis for planning, organization, and construction, 44; atmospheric hygiene, 43 (*Anon. 5, 98*).

Concerned with "the great practical significance of protecting persons from respiratory affection with bacterial toxin," an investigation is studying this potential in *Bacillus botulinus* toxin, "which has no equivalent in strength" (*Yakovlev 5, 56*).

For potential rabies victims, it is recommended that antirabies gamma globulin containing specific antibodies be applied directly to the wound, in conjunction with antiseptics and antibiotics, before administration of the vaccine. (*Solov'yev 3, 52*).

A lozenge held to be prophylactic against streptococci, staphylococci, and other microbes consists of 1,000 gamma gramicidin, 0.07 gram ascorbic acid, 0.002 gram tannin, and 1 gram of sugar and filler (*Anon. 2, 72*).

Persistence of rabies, especially among foxes and other wild animals, has prompted production of a hyperimmunization serum by the State Institute for Rabies Inoculation at Potsdam (*Starke 10, 81*).

Aerosols of volatile oils in a sealed room were found to be effective against *Staphylococcus albus* at Kiev. Eucalyptus appeared to be the most effective oil tested; lavender the least (*Vedibeda 8, 70*).

Production of diagnostic materials in the Soviet Union is deficient with respect to brucellosis, tularemia, and many viral and rickettsial diseases (*Meshalova 9, 72*).

Immunization against brucellosis can be combined with simultaneous subcutaneous inoculation against tetanus, investigators in Moscow conclude on the basis of animal experiments (*Chian Shun-ch'u 16, 74*).

Epidemiology

Among measures recommended at the 12th session of the U.S.S.R. Academy of Medical Sciences, it was proposed: A statistical bureau for the study of the role of population factors in pathology and for working out the methodological indexes for the study of hereditary

diseases should be established in the Institute of the Organization of Public Health. A laboratory of the heredity of man and a laboratory of radiobiology should be organized within the Institute of Experimental Biology and the Institute of Experimental Medicine, U.S.S.R. Academy of Medical Sciences (*Anon. 6, 63*).

Pathology, immunology, and mode of transmission of influenza is being investigated, with respect to the biological and colloid-chemical properties of a virus aerosol trapped in a sponge filter made of gelatin (*Rechmenskiy 1, 68*).

The mucous membrane of the nose is the essential point of infection of animals susceptible to hoof-and-mouth disease, it is concluded from experiments in pathology reviewed for the Thuringian Section of the Scientific Society for Veterinary Medicine in East Germany (*Potel 6, 61*). (This entire review is published in translation.)

Occupational Health

A review of dissertations on labor hygiene by candidates for science degrees found the following topical interests most prominent, in the order given: occupational poisons, industrial dust, physiology of labor, microclimate, industrial trauma, and a miscellany including changes in atmospheric pressure, noise and vibration, morbidity, research methods, and sanitation. The author noted with regret that although the economy requires an increased production of insecticides, only three dissertations related to their toxicity (*Yegorov 16, 85*).

Foam rubber is found satisfactory as a dust filter in face masks tested at the Leningrad Sanitary Hygienic Medical Institute. The filter can be washed with ordinary soap and water and used again effectively, but it offers no "satisfactory standard for pore size" (*Koryukayev 7, 66*).

A cherry-extract drink is found more effective than a 0.5-percent gaseous solution of salt for quenching thirst, preventing dehydration, and maintaining efficiency of men working in high temperatures, according to a Tashkent study, at a Uzbek metallurgical plant. The drink is now the customary beverage in shops where heat is intense (*Anon. 8, 79*).

tories, and 33 pasteurization stations. Registered cases of malaria have dropped from 121,000 in 1950 to 659 in 1956. Smallpox has been "liquidated" since 1936 (*Zairov 9, 57*).

Diphtheria in Byelorussia was reported in 1957 to be 9.8 per 10,000 population, 30.6 per cent below the 1956 rate (*Rubinshteyn 4, 41*).

Environmental Services

In recommending filtration and active dilution of air pumped out of nuclear reactor power stations, a Czechoslovakian paper concludes it is necessary to develop less hazardous types of reactors (*Anon. 2, 67*).

The first "scientific-practical" conference on sanitary inspection of food products for the entire Soviet Union was held in Moscow in June 1958. (Reports of the principal speakers are summarized lightly in the translation.) Leading causes of "food poisoning" were bacterial infection, primarily of meat, followed by dairy products (*Krapivner 16, 84*).

A Committee for the Protection of Atmospheric Air has been established in the Main State Sanitary Inspectorate of the U.S.S.R. Ministry of Health by an order dated May 5, 1958. Chairman is Prof. V. A. Ryazanov, director of the chair of communal hygiene of the Central Institute for the Advanced Training of Physicians (*Anon. 10, 91*). A book on air pollution control, published in 1957, is the subject of a translated review (*Gernet 10, 93*).

Gamma rays are used to sterilize bandages impregnated with antibiotic medication, by the Division of Antiepidemic Defense of the Central Scientific Research Disinfection Institute. The dose to inactivate anthracoid spores is reported to be 1.5-2.0 million roentgens (*Anon. 5, 66*).

Studies of radiopotassium (K^{40}) find 2.3×10^{-11} curies per liter in mixed city sewage, 6×10^{-12} in suburban sewage, and 1.7×10^{-11} curies in sewage from industrial areas. In nature, K^{40} in city sewage is thought to be in the range of 6×10^{-12} curies per liter. The per capita discharge in the city is estimated at 300 micrograms of K^{40} per day, about 2×10^{-3} curies (*Dolivo-Dobrovolskiy 6, 50*).

Nonpathogenic spore soil saprophytes re-

sistant to chlorination in a public water supply of the Donbassvostrest have created difficulties in applying the bacterial count standards for water quality. An investigation is reported in detail (*Natanson 16, 82*).

Preventive Medicine

Merger of rayon hospitals with sanitary-epidemiological stations was discussed at the fifth congress of the Medical Workers' Trade Union, Moscow, May 29, 1958. Golovkova said that with the present workload, a medical district physician has no time to organize preventive work. Popov said that mergers have been beneficial in rural districts, but that the distribution of the physician's work is unsolved.

Delegates also complained that too little attention is given to the health and safety of medical workers, that the Ministry of Health issues directives without enforcing their application. Research workers were chided for giving too little heed to public health needs, but Suchkova in turn chided public health workers for failing to keep up with medical advances.

In order to extend the effectiveness of medical services, with an average of 1 physician for 600 people, M. D. Kovrigina, Minister of Health, urged strengthening outpatient clinics, and said they must arrange to eliminate waiting lines and to treat people in the evenings or on their day off from work. The number of physicians may be increased at the expense of auxiliary branches of the profession. Also, she proposed reduction of the volume of paperwork by doctors.

She and others stressed the value of health education. It was asserted that more than 500,000 medical deputies of Red Cross and Red Crescent societies are seeking to provide health information for the public.

The conference voted approval of a resolution supporting suspension of nuclear tests (*Anon. 4, 54*).

Of 684 themes announced for 86 hygienic establishments of the R.S.F.S.R. Ministry of Health, 284 deal with labor hygiene and prevention of occupational disease. The balance of the score card is: radiation hygiene, 102; water hygiene, 99; hygiene for children and

cent dyes, used in observing agents of herpes, hoof-and-mouth disease, lymphogranuloma, swine plague, chickenpox, shingles, encephalitis, psittacosis, and other viral diseases, has been employed also in the study of tickborne encephalitis. The process is described in translation in detail. An illustration of the apparatus and two electrophoregrams are included in the original paper (*Izotov 8, 68*).

Information Services

It is proposed to expand and expedite publication of reports of Soviet research in radiobiology: fewer than a third of the reports sub-

mitted in 1956 and 1957 have been printed (*Anon. 3, 65*).

Soviet participation in international medical programs has resulted in a rise in their contributions to Western journals and an increased attendance at international conferences. Nearly 2,000 abstracts of works by Soviet specialists have been published in *Excerpta Medica*, and 6 special editions of that journal have been devoted to Soviet works (*Ivanova 7, 88*).

Continuous courses have been organized for raising the qualifications of sanitation physicians, chemists, bacteriologists, laboratory assistants, and workers of sanitary-epidemiological stations (*Anon. 7, 91*).

Translations From Russian Medical Works

The Russian Scientific Translation Program, set up in the National Institutes of Health, Public Health Service, in July 1956, distributed 42 completely translated issues of several Soviet journals to 400 research libraries during 1958. The issues represent a total of 1,470 papers in biochemistry, biophysics, experimental biology and medicine, microbiology, epidemiology, immunology, hematology and blood transfusion, oncology, virology, and physiology.

From the program's inception until October 1957, the activities concerned principally the supply of supplementary materials to scientific groups for their independent evaluation of Soviet experimental work. During fiscal 1958 the emphasis shifted to materials for evaluation, field by field. Future plans include a mechanism to gauge both the needs of the scientific fields for information and the adequacy of the program in fulfilling those needs.

The cover-to-cover translation of basic science journals is a major feature of the program.

Another activity has produced 2,990 abstracts of Soviet medicine in four quarterly issues for both basic medical sciences and

clinical medicine. Another 5,100 more abstracts are in prospect.

The program also provides grants to support preparation of reviews of Soviet literature by American scientists in such fields as cardiovascular physiology, neurochemistry, nutrition, defectology, and air pollution. Also, a list of 300 Russian scientific review papers were sent to about 150 editors of American journals, many of whom requested translation of listed papers. Republication of some papers is scheduled in a number of journals.

Reference works, such as the "Directory of Medical and Biological Research Institutes of the U.S.S.R.," "A Guide to Russian Medical Literature," and a "Russian-English Medical Dictionary," are products of the program, which is also planning the publication in English of selected Russian monographs.

The "Bulletin of Translations From Russian Medical Sciences" lists available translations and services and gives pertinent information about other translation programs, Government and private.

Address inquiries to the Russian Scientific Translation Program, National Institutes of Health, Public Health Service, Bethesda, Md.

Neurophysiological effects of vibrations are the general subject of a series of experiments reviewed in one chapter of a book issued by the State Publishing House of Medical Literature, Leningrad (*Mogendovich* 9, 84).

Protracted systematic vibration retarded the accumulation of body weight in young rats in an experiment performed at the Moscow Sanitary Hygiene Medical Institute (*Lebedeva* 7, 65).

A chemical called Unitol was reported effective in treating 25 clinic patients suffering from absorption of arsenic and mercury compounds (*Belonozhko* 1, 60).

Diagnosis and Therapy

The basic aim of the new Institute of Physiology and Pathology of Women (Institut Fiziologii i Patologii Zhenshchiny) established at Tbilisi by the Georgian S.S.R. Ministry of Health, first of its kind in the Soviet Union, is to increase the birth rate. It seeks to decrease the incidence of abortions and find solutions to infertility (*Anon.* 11, 102).

To detect the presence of cancer in the organism, a Czechoslovakian news report asserts, A. Chizhevskiy, of the oncological institute in Karaganda, has devised a mathematical formula for the movement of blood cells in the veins (*Anon.* 5, 63).

Tetraethylmonothiopyrophosphate was administered subcutaneously in a dose of 0.06 mg/kg. to mice suffering traumatic injury to the sciatic nerve, and induced recovery two to three times more rapidly than in controls. The application of the chemical in victims of poliomyelitis was mentioned as a possibility (*Lenkevich* 11, 75).

Animal experiments indicate that muscles repair and restore themselves more rapidly if supplied with a direct deposit of minced muscle tissue (*Gavrilova* 11, 95).

A transistorized transmitter, 610 grams, 4.4 x 9 x 14 cm., was built by the Institute for Applied Physiology of the East German Academy of Social Hygiene, Labor Hygiene, and the Advanced Training of Physicians, Berlin. It is used for obtaining electrocardiographs (*Frucht* 14, 79).

Tape recordings are being used to hypnotize

some patients in the psychotherapeutic department, headed by Dr. Wicht, in the polyclinic of the Friedrich-Schiller University of Jena, which celebrated its 400th anniversary in 1958 (*Anon.* 7, 94).

Use of radiophosphorus to diagnose breast cancer produced some evidence that absorption of phosphorus by the malignant tumor depends on the intensity of the processes of renewal of the nucleic acids in the growing area (*Dmitriyeva* 4, 66).

A Czechoslovakian spray gun for treatment of second-degree burns uses a mixture of thrombin, antibiotic, plasma, and oxygen to form a film (*Bares* 10, 86).

Ordinary gypsum, used in therapy of burns, is reported to be an excellent physical antiseptic, also eliminating pain in the burned area and preventing plasmorrhesis. It was applied to 264 patients at the surgery clinic of the Odessa Institute for the Advanced Training of Physicians. Burns of 34 patients covered more than 40 percent of the body (*Mechnik* 8, 66).

Eradication of schistosomiasis by mass treatment is a near-term objective of the People's Republic of China (*Kochergin* 11, 99).

Artificial teeth were implanted in jawbones of unspecified animals. Connective tissue grew in the canals of the plastic roots and ossified. Attempts at implants in humans were not successful, but experiments with nonirritating alloys are in preparation (*Bazhanov* 1, 76).

Laboratory Services

Dead or alive, rickettsiae are made visible for study by fluorochromes and special optical apparatus. Clearest contrast and most intensive luminescence was achieved by staining the organisms with rivanol or auramine in an aqueous solution, one part to a thousand (*Mitereva* 4, 44).

For observing ornithosis virus particles by means of fluorescence under a microscope, an aqueous solution of acridine orange (1:30,000) is reported to be the most effective dye. A bright green light contrasts with dull luminescence in other formations (*Neustroyev* 16, 69).

Luminescent microscopy, employing fluores-

- The Soviet Union's system of medical care does not provide for free choice of physician by the patient, nor does it usually allow the physician to select his place of practice.

- Soviet medicine is, to a large extent, dependent upon clinical diagnosis with a minimum of laboratory support. The Soviet pharmacopeia in practice is much more limited in quantity and quality than that in the United States as to range of available antibiotics and chemotherapeutic agents.

- The Soviet Union is giving high priority to the extension of medical care and the improvement of health. Health and medical services are provided without cost to all citizens of the Soviet Union.

- Special attention is given to mothers prior to delivery of their children and during the postpartum period. Facilities are widely provided for daytime care of preschool children so that mothers can be released for work. Health departments are taking an active part in city planning from the standpoint of sanitation and health facilities.

The five-man mission consisted of Dr. Thomas Parran, chairman, former Surgeon General of the Public Health Service (1936-1948), now president and trustee of the Avalon Foundation, New York City; Dr. Otis L. Anderson, Assistant Surgeon General for Personnel and Training, Public Health Service; Dr. Henry van Zile Hyde, Assistant to the Surgeon General for International Health, Public Health Service; Dr. Malcolm Merrill, California State director of public health; and Dr. Leonid S. Snegireff, associate professor of cancer control, Harvard School of Public Health.

The mission's findings are contained in "The Report of the U.S. Public Health Mission to the Union of the Soviet Socialist Republics" (Public Health Service Publication No. 649). It may be purchased from the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C., at 45 cents a copy. Single sample copies may be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D.C.

A typical market scene and food displays in the Asian Republics, where farm produce is sold for private profit in the open market.

Public Health Mission

to the

SOVIET UNION

AN "almost explosive extension" of disease prevention and medical care has taken place in the Soviet Union but the quality of service falls short of that found in the United States, according to the report of a mission of five American physicians who visited the Soviet Union late in 1957 under the U.S.-U.S.S.R. exchange program.

With the objective of studying public health problems and practices, the group traveled 8,500 miles and visited 61 institutions in 9 cities in 5 of the Soviet Republics during the period August 13-September 14, 1957. They found that medical care in the Soviet Union has been "tackled with vigor." There is a high ratio of physicians, and many hospitals have been built to serve the cities and rural areas. The group also found, however, that the Soviet Government has deliberately focused on quantity and widespread coverage of personnel and services at the expense of quality.

The report states that Soviet medical establishments are "antiquated or jerry-built" in contrast with those in the United States. It points out, however, that there are "certain ingredients in their political system and in their ability to accomplish mass transfer of brain and brawn from one field of endeavor to another which could permit astonishingly rapid changeover and developments in medicine as impressive as the appearance of Sputnik."

Pestilential diseases and the diseases of filth have been substantially brought under control. Malaria as a significant health problem is on the way to eradication. Venereal disease has

been mastered, but tuberculosis remains a plague.

Types of institutions visited included administrative public health headquarters, industrial health services, medical teaching institutes, "medium-medical schools," medical research institutes, local public health facilities, sanitary-epidemiological stations, urban and rural health centers, child nurseries ("creches"), rest homes, city markets, industrial plants, collective farms, and a number of other special medical facilities and institutions.

Other findings of the mission include:

- The health program of the Soviet Union is, like all programs, subject to the needs of the state and is therefore circumscribed by a series of allocations and goals. The health program is an instrument of state policy because the Soviet Union recognizes the importance of having a healthy working class if it is to achieve its major goals.

- Women represent the majority of practicing physicians in the Soviet Union.

- Medicine is considered an important but not a primary contributor to the Soviet economy. The average Soviet physician does not enjoy the same status as a Soviet engineer.

- The number of physicians trained annually exceeds the number trained in the United States, but the quality of basic training is at a much lower level.

- Clerical help and office equipment of the kind found in United States medical facilities are regarded as "unheard-of luxuries."

- The Soviet Union's system of medical care does not provide for free choice of physician by the patient, nor does it usually allow the physician to select his place of practice.

- Soviet medicine is, to a large extent, dependent upon clinical diagnosis with a minimum of laboratory support. The Soviet pharmacopeia in practice is much more limited in quantity and quality than that in the United States as to range of available antibiotics and chemotherapeutic agents.

- The Soviet Union is giving high priority to the extension of medical care and the improvement of health. Health and medical services are provided without cost to all citizens of the Soviet Union.

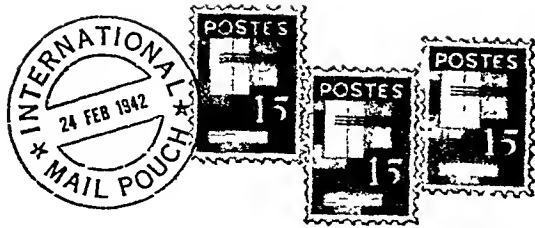

- Special attention is given to mothers prior to delivery of their children and during the postpartum period. Facilities are widely provided for daytime care of preschool children so that mothers can be released for work. Health departments are taking an active part in city planning from the standpoint of sanitation and health facilities.

The five-man mission consisted of Dr. Thomas Parran, chairman, former Surgeon General of the Public Health Service (1936-1948), now president and trustee of the Avalon Foundation, New York City; Dr. Otis L. Anderson, Assistant Surgeon General for Personnel and Training, Public Health Service; Dr. Henry van Zile Hyde, Assistant to the Surgeon General for International Health, Public Health Service; Dr. Malcolm Merrill, California State director of public health; and Dr. Leonid S. Snegireff, associate professor of cancer control, Harvard School of Public Health.

Cambodian School

The teaching staff of the new school of nursing and midwifery in Phnom Penh is entirely Cambodian. Two nursing education advisers of the World Health Organization were asked, as a courtesy, to teach certain classes, but the school is almost wholly a Cambodian undertaking. Three of the faculty members are former trainees sponsored by the U.S. Operations Mission. Another trainee, who is studying nursing education in Montreal, Canada, will head the midwifery section of the school when she returns.

—CARLETON B. WHITE, M.D., *chief, Public Health Division, U.S. Operations Mission, Cambodia.*

House of Earth

A self-help plan is assisting city dwellers in Brazil to build and own their own homes at a cost of \$135 for materials. Serviço Especial de Saúde Pública has adapted to municipalities the aid system traditional in farming areas. A prefeitura, or municipal government, after creating the self-help service by municipal law, signs an agreement with SESP for administrative operation of the project by SESP engineering, public health education, and other staff members.

The houses, built according to minimum standards under this pilot project, have two rooms and a veranda which serves as kitchen and living room. Walls are of soil-cement blocks made by machine and compacted by the people themselves. The city grants the land, and materials are bought from a rotating fund made up of annual contributions from SESP and the municipality. The owner has 4 years to repay the loan; afterwards he owns the house he helped to build.

The Serviço has published "Casa de Terra," by Alvaro Milanez, technical consultant to SESP, which indicates some of the techniques, such as

rammed earth, adobe, wattle and daub, sod, and soil-cement, used in earth construction. The booklet is not a construction manual but is designed as a guide for public health workers and technicians in assisting those who want to build or improve dwellings. "Casa de Terra" can be obtained through the Health and Sanitation Division, U.S. Operations Mission, Brazil, for 50 cents a copy.

—E. ROSS JENNY, M.D., *chief, Health and Sanitation Division, U.S. Operations Mission, Brazil.*

Male Prerogative

Only the men became ill after a community birthday party in Songsa Ri, Korea, where the 400 villagers all have the same name and are all related to each other in some way.

At the invitation of the director of the Wondong health center, I went to investigate the outbreak; 38 men were still extremely sick 1 or 2 days after the celebration. I discovered the fried pork served at the party came from two pigs. One had died of natural causes, and the other had been ill prior to slaughter. *Salmonella* organisms were later isolated.

None of the women or children were ill because the men of Songsa Ri, following the custom of rural Korea, had dined first and eaten all the pork.

—WALDO SMITH, *sanitarian, U.S. Operations Mission, Korea.*

Precursor

Of much more value than Freud for his people is a dream book written by a Moslem healer, Ibn Sireen, said the first psychiatrist in the Sudan, Dr. Tigani el Mahi. However, the psychiatrist found a similarity between Freud and Sireen, who lived more than a thousand years ago. "Our book says that dreams are prophetic. Freud says dreams express wish fulfillment. What is prophecy but the foretelling of wishes coming true?" said Dr. Mahi, who spoke at the 1959 meeting of the American Orthopsychiatric Association in San Francisco.

When he returned to the Sudan after training in London, Dr. Mahi said he was surprised by the valid psychological insights of religious healers and medicine men in his country. He said he often referred patients to them, and they, in turn, were beginning to refer patients to him.

Infectious Encephalitis

In Colorado

LUTHER E. GIDDINGS, M.D.,
STEPHEN G. COPPS, M.D.,
CLARENCE A. SOOTER, Ph.D.

BETWEEN May 1, 1956, and December 31, 1957, 258 cases of infectious encephalitis in Colorado were reported to us by physicians, hospital personnel, local health departments, and the Colorado State Department of Public Health. For most of these cases, it was necessary for us to rely on the clinical judgment of those making the diagnosis; since the acute phase of the illness had generally passed by the time the case was reported, laboratory diagnosis was not possible. Infectious encephalitis is generally defined as an acute disease process in which the patient exhibits typical signs and symptoms of central nervous system involvement (headache, fever, stiff neck and back, drowsiness, and spinal fluid pleocytosis) with a micro-organism as the presumed etiological agent.

This paper presents certain epidemiological aspects of this syndrome observed in the above-mentioned cases and compares some of these aspects as they differed according to the etiological agent involved.

Methods

Attempts were made to gather basic epidemiological information on all cases as they were reported. This information included, among other things, geographic, time, age, and sex data for each case. At the end of the 20-month period these isolated bits of information were compiled to demonstrate the geographic, time, age, and sex distributions of the cases.

Serum specimens were collected from patients when possible. In general, these specimens were paired, with one specimen taken early in the course of the disease (acute phase) and the second taken 3 to 6 weeks later, during

convalescence. Occasionally, only convalescent-phase specimens could be collected.

All specimens were tested with the hemagglutination-inhibition (HAI) test for antibodies against St. Louis encephalitis (SLE) and western encephalitis (WE). Most of the specimens were also tested with the serum neutralization (SN) test for antibodies against the same diseases. If sufficient sample remained it was tested with the complement fixation (CF) test for antibodies against mumps, lymphocytic choriomeningitis (LCM), and eastern encephalitis (EE) in addition to SLE and WE. (All CF tests were performed by the Communicable Disease Center, Virus and Rickettsia Laboratory, Chamblee, Ga.) The three poliomyelitis types were added to the CF battery in 1957. Also in 1957, convalescent-phase specimens from 27 patients which showed insignificant antibody titers in all the above tests were subjected to the SN test for ECHO viruses, types 2, 4, 6, and 9, and serums from 18 patients were subjected to the SN test for Colorado tick fever. (Tests for ECHO viruses were performed by the department of pediatrics, University of Colorado Medical Center, Denver, Colo. For Colorado tick fever, tests were performed by the Rocky Mountain Laboratory, Hamilton, Mont.)

A case was considered serologically "confirmed" if a fourfold rise in HAI or CF titer or tenfold rise in neutralization index could be demonstrated in paired specimens. A case was considered serologically "suggestive" when a CF titer of 1:8 or HAI titer of 1:80 was present but a rise in titer could not be demonstrated. The cases were then categorized ac-

Dr. Giddings, at the time of this study, was epidemic intelligence service officer with the Encephalitis Investigations Unit, Greeley Field Station, Communicable Disease Center, Public Health Service, Greeley, Colo. He is now a resident in pediatrics at Salt Lake County General Hospital, Salt Lake City, Utah. Dr. Copps, formerly on the staff of the Children's Hospital, Denver, Colo., is now with the Medical Corps, U.S. Army, Fort Riley, Kans. Dr. Sooter, formerly chief of the Greeley Field Station, is currently executive secretary, Research Fellowships Branch, Division of Research Grants, National Institutes of Health, Public Health Service.

Table 1. Etiology of 258 cases reported as infectious encephalitis in Colorado between May 1, 1956, and December 31, 1957

Classification	Method of diagnosis	Number of cases
St. Louis encephalitis	Serologic	21
Probable St. Louis encephalitis	do	27
Western encephalitis	do	20
Probable western encephalitis	do	5
Mumps	do	1
Mumps	Clinical	23
Measles	do	1
Influenza	do	4
Influenza	Serologic	1
Postvaccinal encephalitis	Virus isolation	1
Poliomyelitis type 1	Clinical	1
Poliomyelitis type 2	Serologic	2
Colorado tick fever	do	1
Etiology unknown	do	1
		149

cording to etiology by month of onset and age and sex of the patient.

Results

Study revealed that the 258 cases were, for the most part, roughly distributed in proportion to population density throughout Colorado. There were two exceptions to this rule. One was Grand Junction in Mesa County, and the other, the plains area in eastern Colorado. An

unusually high attack rate was seen in both of these places as a result of localized outbreaks of SLE in the summer of 1956. Cases were reported in each of the 20 months under discussion. The majority of the cases, however, are grouped together into two separate time periods: the late summer and early fall months of 1956 and the same period in 1957.

Each age group was involved, with the youngest patient 6 days of age and the oldest 82 years. There was, however, a marked preponderance of cases among people under 20 years of age, particularly among those under 10.

The etiological agent was defined by laboratory or clinical means in 109 of the 258 cases (table 1). The arthropod-borne diseases, SLE and WE, accounted for 67.0 percent of the cases in which the etiology is known, while mumps accounted for 22.0 percent. Influenza was next in line, followed by poliomyelitis, measles, Colorado tick fever, and postvaccinal encephalitis.

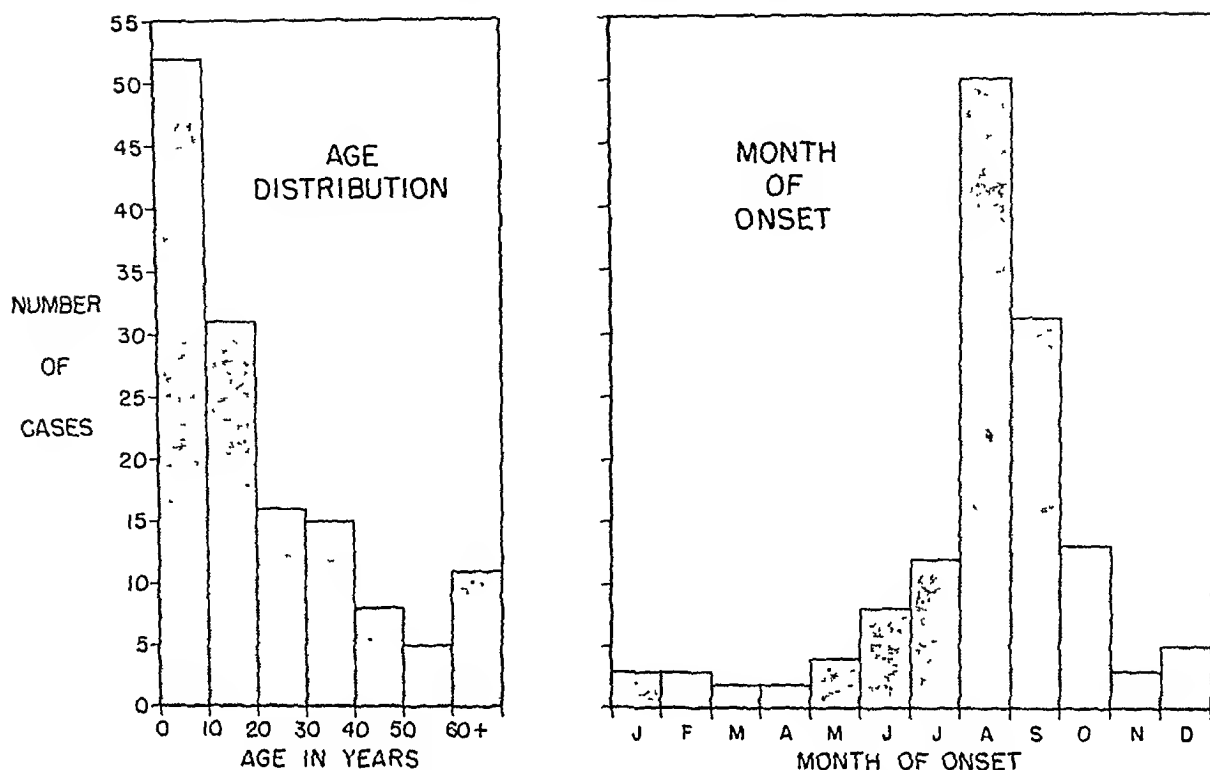

An effort was made to exclude cases of nonparalytic poliomyelitis from the study. The three cases that are included were originally reported as infectious encephalitis, and it was only on subsequent serologic examination that the true etiology of the disease became known. On the other hand, two cases which were originally reported as nonparalytic poliomyelitis were subsequently found, on serologic exami-

Table 2. Results of serologic tests for various etiological agents of infectious encephalitis

Disease	Ratio of cases ¹ to paired specimens tested			Percent positive of those tested
	1956	1957	Total	
St. Louis encephalitis				
Western encephalitis	43/61	5/64	48/125	38.4
Mumps	3/61	22/64	25/125	20.0
Lymphocytic choriomeningitis	0/45	1/46	1/91	1.1
Eastern encephalitis	0/45	0/46	0/91	0
Poliomyelitis type 1	0/45	0/46	0/91	0
Poliomyelitis type 2	0/0	2/46	2/46	4.4
Poliomyelitis type 3	0/0	1/46	1/46	2.2

nation, to be WE. The largest group, unfortunately, is that in which the etiological agent is unknown. This group is composed of 149 cases, or 57.8 percent of the total number.

Results of the serologic tests can be seen in table 2. The largest number of specimens (125) were tested for antibodies against SLE and WE. These two diseases, in order, were responsible for the largest numbers of serologically confirmed and suggestive cases. Fifty percent of those tested for Asian influenza were confirmed to give the highest ratio of cases to paired specimens tested in this series. However, this involved serum specimens from only two individuals. SLE was next highest with 38.4 percent, followed by WE with 20.0 percent. Smaller percentages were noted for the other diseases mentioned previously. Low-level antibody titers against various types of ECHO virus were found to be present in 8 of the 27 (29.6 percent) convalescent-phase specimens tested. None of the specimens had antibodies against type 4, two had antibodies against type 2, six had antibodies against type 6, and five

had antibodies against type 9. Two specimens had antibodies against types 6 and 9, one against types 2 and 9, and one against types 2, 6, and 9. No attempt will be made to interpret these results since it is not known whether any of the serums underwent a rise in titer. Attempts at interpretation would be made still more hazardous by the lack of knowledge concerning the presence of such antibodies among the general population in this area. One of the 18 (5.6 percent) tested for Colorado tick fever was considered "confirmed" on the basis of an 18-fold rise in neutralizing titer. Moderately high titers were demonstrable in the serum of three other patients, but, again, since there was no significant rise in titer, no attempt will be made at interpretation.

As noted previously, the largest group studied was that in which the etiology was unknown. Age distribution and distribution by month of onset for that group are given in figure 1. The seasonal distribution for the next three largest groups, SLE, WE, and mumps, may be seen in figure 2, and the age distribution

Figure 2. Seasonal distribution of western encephalitis, St. Louis encephalitis, and mumps encephalitis, Colorado, May 1, 1956–December 31, 1957.

in figure 3. The age distribution was somewhat alike for WE, mumps, and cases of unknown etiology in that the disease was primarily in individuals under 20 years of age. SLE showed fairly even case distribution among all age groups with only a slightly larger number of cases among older people. The seasonal distribution of cases of unknown etiology (fig. 1) looks somewhat like a composite of the distribution of SLE, WE, and mumps (fig. 2), with cases occurring in each month of the year. An increase in the number of cases starts in May, continues through June and July, and reaches a peak in August. From there it declines gradually through the month of October. WE and SLE are restricted to the late summer and early fall months, while mumps is seen in all seasons, but primarily in the spring. The sex distributions, shown below, for WE, SLE, and mumps are similar, with more males than females in each group.

	Number of cases		
	WE	SLE	Mumps
Male.....	16	23	18
Female.....	7	19	6

There were 10 deaths among the 258 patients. One of the fatal cases, with signs and symptoms typical of encephalitis, was felt to be due to Asian strain type A influenza since the virus was cultured from a piece of lung tissue taken at autopsy. Two of the deaths were thought to be possibly due to SLE because of moderately high antibody titers in specimens taken during the acute phase. In each case the patient died before a second specimen could be obtained. Virus isolation attempts were made on a section of brain from one of the two patients, but no viruses were obtained.

Discussion

The fact that the cases of infectious encephalitis observed were distributed roughly in proportion to the human population would lead one to believe that the causative agents are widely distributed within the State. All the agents are not known, but SLE, WE, and mumps would appear to be particular problems. However, since a special effort was made to search out cases of SLE and WE, it may be that

Figure 3. Age distribution of western encephalitis, St. Louis encephalitis, and mumps encephalitis, Colorado, May 1, 1956–December 31, 1957.

the importance of these two diseases is exaggerated. It is entirely possible that an even greater problem lies hidden among those cases of unknown etiology but we have no evidence of such. It is only possible to theorize concerning the possible agents involved in that group. It would seem likely that some of the cases on which laboratory procedures were not carried out were nonparalytic poliomyelitis and WE, or were due to encephalitogenic types of ECHO or Cocksackie viruses. This assumption can be borne out to a minor degree by comparing the age distribution and epidemic curves of these cases of unknown etiology (fig. 1) with those of outbreaks of the diseases mentioned above (1-3). The significance of the presence of antibodies against certain types of ECHO viruses among some of these patients is not known. SLE can also be compared as far as the epidemic curve (fig. 2) is concerned, but the age distributions do not compare well (fig. 3). A number of those cases which occurred in the winter, spring, and early summer might very well have represented mumps encephalitis without clinical parotitis. It has been noted in the

past that as many as 50 percent of the cases of mumps encephalitis fit into this category (4).

Unfortunately, many cases of encephalitis are never reported to authorities in Colorado. With more complete reporting and the submitting of specimens for testing from most of the encephalitis patients, it seems likely that mumps would become the largest etiological group, as it is in California (5). An additional problem is the confusion in attempting to differentiate between nonparalytic poliomyelitis and infectious encephalitis on a clinical basis. It is generally agreed among those who do a great deal of work with acute diseases of the central nervous system that the only reliable way to make such a differentiation is on the basis of laboratory findings.

Probably the most striking feature, though one that would not be unexpected, is that all cases of mumps encephalitis were seen in patients under the age of 20. While WE shows a tendency to infect people of most ages, it is obvious that this disease, like mumps, attacks more people in the younger age groups than in the middle and older age groups.

SLE tends to infect people of all ages, with a slight preference for the older age groups. The difference between mumps and SLE can be explained by the fact that mumps is a highly infectious disease, endemic in most areas of this country, which becomes epidemic whenever a sufficient number of people who are not immune are present. This means that as children are born following a mumps epidemic the stage is being set for a new epidemic several years later. As a result of these frequent epidemics most people become immune before reaching an advanced age. SLE and WE, on the other hand, while they are both endemic in Colorado (6), can probably be spread only by the bite of an infective mosquito (7). The incidence of these two diseases in a community is therefore dependent on mosquito populations and mosquito infection rates and numerous other poorly understood factors. In light of our present knowledge, the age distribution differences between SLE and WE cannot be explained.

The preponderance of male patients infected with the SLE and WE viruses could possibly be explained by the fact that men and boys in general spend more time out-of-doors and are, hence, at greater risk of exposure to infective mosquitoes. This does not, of course, hold true with infectious parotitis since both sexes are generally affected equally (8).

Summary

A total of 258 cases of encephalitis were brought to the attention of the authors between May 1, 1956, and December 31, 1957. There were 10 deaths in this group. Geographic, time, age, and sex distributions of the cases were noted.

The viruses of SLE, WE, and mumps were the most common causative agents. Epidemiological characteristics of these three types of encephalitis were compared.

More diagnostic work needs to be done in the field of infectious encephalitis in order better to evaluate the problem brought about by the large number of agents which can produce this syndrome.

HORIZONS in Rural Health

THE 14th National Conference on Rural Health was held in Wichita, Kans., March 5-7, 1959, under the sponsorship of the Council on Rural Health, American Medical Association. Representatives of farm organizations, the council, and State medical societies, and workers in the agricultural extension service and in official and voluntary health agencies attend these conferences, held in a different part of the country each year.

The Council on Rural Health is the official body representing the rural health interests of 160,000 physicians who constitute the American Medical Association. The group was appointed in 1945 by the association's board of directors in response to an invitation from the American Farm Bureau Federation to join with it in a study of the rural health situation. Dr. Franklin S. Crockett, Lafayette, Ind., has been chairman since 1945. Advisers have been added to the original group to increase representation of agricultural producers and educators.

Every national conference has stressed the theme of self-help and the roles of the individual general practitioner and the individual citizen in meeting personal and community health needs.

During recent decades, many changes have taken place in rural America. The city-limit sign no longer sets families living in towns apart from those living in the open country, with each having different sets of living standards and widely differing opportunities for health services.

Many factors have contributed to a revolution in farm family living: electricity on the farm and in the farm home, improved roads, greater ease of travel, and higher family income. New hospital construction, particularly since the 1946 enactment of the national hospital and medical facilities construction program, has helped to arrest the decline of health services in rural areas. Voluntary health insurance as a means of budgeting family medical and hospital expenses has been widely

SLE tends to infect people of all ages, with a slight preference for the older age groups. The difference between mumps and SLE can be explained by the fact that mumps is a highly infectious disease, endemic in most areas of this country, which becomes epidemic whenever a sufficient number of people who are not immune are present. out as "an unparalleled achievement in disease prevention." Where fluoridated water is not available, topical application of fluorides to the teeth greatly reduces dental caries.

Accidents

Accidents result in approximately 12,000 deaths and another 1 million injuries among rural people in the United States annually. Because of this record, the National Grange asked its 7,000 local groups to keep account of accidents in their communities during the past year. In addition, nearly 1,000 local granges sponsored local safety programs.

Occupational health programs for people employed in agriculture are in their infancy. Farm mechanization has increased at a rapid rate without the same attention to safeguards against accidents that has been given in industry. Brucellosis and other animal diseases communicable to man are another hazard of farming, and the continued cooperation of the medical profession, public health agencies, and local citizens is required to control them.

Future Needs

Dr. Franklin Murphy, chancellor of the University of Kansas, outlined major needs for the future:

- More planned organization of area medical service, carried out by governmental agencies, citizens, and other groups working jointly, with patients and services flowing freely in both directions from the center to the periphery.

- Continued remodeling of professional education, both for the medical student and the practicing physician, to produce the best kind of family physician.

- Medical practice by teams of physicians rather than solo practitioners in rural areas.

Roy Battles, speaking for the National Grange as well as for other rural people, concluded that now that we have had our health horizons lifted, our personal dimensions of disease prevention and cure broadened, our knowledge of many maladies expanded, we want all the first-class medical services that we have read about.

In delineating the areas of need, he said: "Too many people do not know about or concern themselves with preventive care. Too many rural people are too fat. Too many are involved in accidents. Too many have to wait too long in the doctor's office. Too many communities have their doctors spread too thinly. . . . The same general trend is evident in varying degrees in the case of hospitals, clinics, public health services, nursing homes. . . . Rural people have a long way to go just to catch up to our urban neighbors."

CDC Courses in Insect and Rodent Control

Refresher training in insect and rodent control will be offered at the Communicable Disease Center, Atlanta, Ga., from September 1959 through June 1960, according to the following schedule:

Insect control. September 14-25.

Rodent control. September 28-October 9.

Mosquito control. November 2-6.

Identification and biology of arthropods of public health importance. January 11-22.

Epidemiology and control of vector-borne diseases. February 15-19.

Insect and rodent control. June 6-17.

There are no tuition or laboratory fees for

the courses. Students will be accepted from State and local health departments, the Armed Forces, and other organizations concerned with insect or rodent control. Qualified students from other countries will be accepted and given opportunity to study vectors of important diseases. Applications for any of these courses should be submitted at least a month before the course begins.

Application forms may be obtained from the Chief, Training Branch, Communicable Disease Center, Public Health Service, 50 Seventh Street NE., Atlanta 23, Ga.

adopted by rural as well as urban families. Rural families can now command to a far greater extent than in the past the services once available chiefly to families in cities.

Still problems persist, and the need continues for a partnership among practicing physicians, rural people, and other groups which can contribute to their solution. Among other problems, this year's National Conference on Rural Health emphasized aging, mental health, and dental health.

Aging

Problems of the aging represent a growing challenge to rural communities, many of which have a disproportionate share of their population in the older age brackets. As a first step toward meeting the needs of the aging, Aubrey Gates, field director of the Rural Health Council, suggested making an inventory of a community's assets in the form of its elder citizens. How many are there? What knowledge and skills do they have of value to their community? How can these continue to be used?

He called for community action to employ the skills of the aged productively, to consider and provide for the needs of older people for housing and recreation opportunities, to plan for the building and maintenance of safer, more modern facilities for care of those who cannot remain at home, and to plan for better home care and visiting nurse service for those whose disabilities require outside assistance although care away from their own homes is not necessary.

Local churches and other organized community groups can help to stimulate and conduct programs to keep the aged an integral part of community life, and to stimulate and advise other groups having responsibility for meeting the health needs of the aged. Rural families can participate in such activities and lead in their development.

Other conference speakers emphasized what people can do for themselves throughout their lives that will help to prevent or alleviate problems of age. Planning in youth and in the middle years can avoid some of the economic as well as the physical and emotional hazards that beset later years. Preparation for senior

citizenship should include attention to proper diet and exercise, cultivation of interests outside the job, and regular physical checkups to detect and treat disease while recuperative powers are still high.

Mental Health

The need for a change in public expectations regarding mental hospitals was discussed by Dr. Prescott Thompson of the Menninger Clinic at Topeka, Kans. In the past, these hospitals were, in fact, asylums in which the mentally ill were doomed to spend their lives, separated from society and with no hope for rehabilitation to restore their capacity for normal living. Now an increasing number of former mental patients are returning to normal lives in their own families and communities. In many cases, local attitudes make such a return difficult, since these attitudes are still based on the old concept of a mental hospital as an asylum where those who enter have no chance to recover from illness.

Some communities have recognized the serious national shortage of trained people for community mental health programs. They have sponsored institutes for ministers, school guidance personnel, and others in a position to provide mental health counseling to local people.

Dental Health

Mrs. E. Arthur Underwood, a practicing dentist of Vancouver, Wash., suggested taking a child to the dentist early as a way to help the child feel that the dentist is his friend, not a person to fear. Parents' attitudes also influence a child's attitude toward the dentist. Frequent visits to the dentist are needed even at an early age to have cavities filled, to prevent further spread of dental disease, and to remove accumulated tartar.

Protection against decay is possible at home through substituting fruit, carrots, and celery, and other low carbohydrate foods for cookies and candy for afterschool snacks. Adequate brushing of teeth will help to remove the food residue that is necessary for bacteria to flourish.

Going beyond action by the individual and family, fluoride in drinking water was pointed

different wards and placed in a convalescent cottage where the professional staff could give them close attention.

The doctors concluded that 55 of these 72 patients were well enough, after intensive treatment, to leave the hospital if they had the incentive to do so and a suitable home to go to. For some it was too late—they had lived at the hospital so long that it was home to them and they did not want to leave. But 26 of the 72 did leave, and all but one of these got jobs and became self-supporting.

To keep such persons in mental hospitals all their lives is not only to fail in a duty of common humanity but it is false economy. Let us say that it would have cost \$1,500 a year, the national average, to maintain these 25 patients in the hospital for the rest of their lives and that they had an average life expectancy of 20 years. This would amount to a total cost of \$750,000—three quarters of a million dollars to maintain in a mental institution for the remainder of their lives 25 men who proved to be perfectly capable of becoming productive members of society.

Similar evidence that large numbers of patients in mental hospitals today need not be there was produced in a study supported by the National Institute of Mental Health at a hospital in California. In this study, 235 long-term patients were given intensive treatment and their record of improvement compared to that of a matched control group. The recovery rate among the special treatment patients was $2\frac{1}{2}$ times that of patients in the control group.

It must be recognized, of course, that it is not easy for a former mental patient to make the transition from hospital to community life. One of the greatest difficulties in making the transition has to do with earning a living. Here there are positive barriers, far more formidable ones than those which many employers put up against hiring the physically handicapped.

A great deal more needs to be done to pave the way for employment of former mental patients, an area that does not require large outlays of money but the priceless ingredients of public compassion and understanding.

The Department of Health, Education, and Welfare, I am happy to report, has been qui-

etly working on this aspect of the problem as an employer. Several persons who have been patients at St. Elizabeths Hospital are employed right now in various agencies of the Department and are doing very well.

These patients were started in carefully selected jobs, working at the Department during the day and returning to St. Elizabeths at night. Nearly all of these patients have gone on from these especially selected positions to regular employment either in the Department or in private industry.

Statistically, of course, this program is not significant. Altogether only about two dozen patients have been involved so far. But the success of this program, it seems to me, should have great significance for all employers.

I think everyone would agree that much could be accomplished if industry, large and small business, public and voluntary agencies, and others concerned applied effort and time toward breaking down the barriers to employment of former mental patients.

There are also large numbers of patients in mental hospitals today who, although not employable, could be cared for much more satisfactorily outside the hospital.

The traditional idea of caring for all mentally ill people in one big institution, regardless of the type or severity of their illness, is being seriously questioned by competent authorities as an effective means of dealing with this vast and complex problem. There are, for example, thousands of elderly people in mental hospitals who could be cared for much better in nursing homes or other facilities more suited to their needs.

A concerted movement in this one direction alone would greatly reduce overcrowding of mental hospitals and the heavy burdens now imposed on limited hospital staffs.

The National Institute of Mental Health provides advisory services and matches State funds to help communities build facilities and provide services for such people. The Institute also offers mental health project grants specifically designed to support projects for the development of new and improved methods of care and treatment for mental patients.

A fully effective attack on mental illness requires not only greater effort to get people out

*By Arthur S. Flemming, Secretary of Health,
Education, and Welfare, April 20, 1959*

Care of Mental Patients

TENS of thousands of mentally ill patients in our Nation today are receiving disgracefully inadequate care and treatment.

While there has been some encouraging progress against mental illness in recent years, the situation as a whole is one that I believe the American people would find genuinely shocking if they knew the facts.

I recognize that this is an immensely difficult problem, aggravated by too little scientific knowledge and to a considerable extent, even today, by old fears and superstitions.

One thing, however, is clear: The resources we are devoting to mental illness today fall dreadfully short of meeting the problem. We have not yet mounted an effective attack on mental illness in this country. The fact is, we are barely holding the line.

One does not need to dig very deep into this problem to uncover some shocking deficiencies. I am satisfied that, on the whole, we are beginning to make real progress in the area of research. But in the area of hospital care and treatment, we are far behind.

Many of the 277 State and county mental hospitals in this country are still little more than custodial institutions with wholly inadequate funds, personnel, and facilities for even the simplest methods of treatment.

For the Nation's public mental institutions—where about 9 out of 10 of those in mental hospitals are today—the average expenditure for both care and treatment is only \$4.07 per patient per day. When we compare this with the average cost of \$26 per patient per day in general hospitals, exclusive of physicians' fees, we get some idea of what the great majority of

patients in public mental institutions are up against.

The average expenditure of \$4.07 per patient per day in public mental institutions becomes even grimmer when we take into account the fact that most mental hospitals today devote their best facilities and personnel to the treatment of newly admitted patients whose chances of recovery are greatest.

Today, a patient entering a mental hospital has a 50-50 chance of getting out during the first year. After the first year, however, with the resources currently available, the chances of recovery decline sharply. If a patient does not respond to intensive treatment during the first few months, he must be shifted to the chronic wards in order to make room for new admissions.

Patients who do not get well the first year now have only 1 chance in 5 of ever leaving the hospital and after 5 years only 1 chance in 100.

I am advised, however, that the condition of the longer term patients is by no means as hopeless as the statistics would suggest, that a great many of them could be restored to normal, productive lives if adequate treatment were available. Surely a far greater effort than is possible with the resources available today is needed to rehabilitate the longer term patients—the forgotten men and women of the back wards of our mental institutions.

That this would be a fruitful expenditure of time and effort was proved rather dramatically by a study at a Maryland State hospital. In this project, 72 men patients, all of whom had been in the hospital for more than 5 years and some for more than 10 years, were taken from

Federal Publications

Swimming Pools. Disease control through proper design and operation. *PHS Publication No. 665; 1959; by Jerrold M. Miehcal; 147 pages; 75 cents.*

Design, construction, operation, and maintenance of swimming pools and the effect of each on disease control practices are discussed. Prepared as a training and reference guide for use by the Communicable Disease Center in its courses for public health personnel, this manual is intended also for use in State and local inservice training programs.

Swimming. *PHS Publication No. 98 (Health Information Series No. 7); revised 1959; leaflet; 5 cents, \$2 per 100.* Cautions swimmers against overexertion, and warns of unseen dangers. Emphasizes safe practices.

Municipal Water Facilities. Communities of 25,000 population and over, continental United States and territorial possessions, as of January 1, 1958. *PHS Publication No. 661; 1959; 83 pages.*

Changes which have occurred in the organized community water facilities of approximately 850 municipalities since 1956 are reflected in this inventory. Directed to industries, other private agencies, and all levels of government, the report should be useful in planning for broad water developments, industrial expansion, and national emergencies.

Health Statistics From the U.S. National Health Survey. Persons injured, by class of accident, United States, July 1957-June 1958. *PHS Publication No. 584-B8; 1959; 62 pages; 40 cents.*

This report adds information to that already published from the health survey on class of accident and on age, sex, and urban-rural residence of persons injured. The tables cross-classify characteristics of the population with medical attention and activity restriction result-

ing from injuries. They also relate the persons injured to income level and to major activities of working, keeping house, retirement, and school attendance.

Appendixes carry technical notes on methods, give definitions of terms, and show the content of the questionnaire used to collect the information.

National Water Quality Network. Annual compilation of data, October 1, 1957-November 30, 1958. *PHS Publication No. 663; 1958; 239 pages; \$1.50.*

Approximately a dozen chemical determinations and data on coliforms, plankton, organic materials extracted by activated carbon, and radioactivity are set forth in this first annual report following establishment of the water quality network.

The raw data, presented chronologically, were obtained from about 50 sampling stations set up by the Public Health Service and operated cooperatively with local and State agencies. Statistical and other analyses of the data will be published separately.

Psychopharmaca. A bibliography of psychopharmacology, 1952-57. *PHS Publication No. 581 (Public Health Bibliography Series No. 19); 1958; by Anne E. Caldwell; 258 pages; \$1.50.*

Approximately 2,500 articles dealing with psychopharmaca, defined as drugs that primarily affect the mental state, are indexed in a subject list of drugs and again in an author list. The articles are concerned with the effects on psychological, behavioral, and encephalographic reactions of normal subjects, patients, and laboratory animals. They were published between January 1952 and December 1956, with a partial listing for 1957.

To aid the user in locating entries in the subject list, a drug index lists chemical, code, trade, and generic names of drugs, names of drug

groups, trade names of drug combinations, and terms for special therapeutic and research techniques. An ancillary subject list of special conditions contains articles referring to the aged, alcoholism, children, and pain.

Viral Hepatitis. Clinical and public health aspects. *PHS Publication No. 435; revised 1959; by Heinz Eichenwald and James W. Mosley; 56 pages; 20 cents.*

Directed to public health workers and physicians, this manual contains comprehensive discussions of the diagnosis, prevention, and treatment of hepatitis, and of the role of the health department during an epidemic. Appendixes outline information applicable to the operation of mass inoculation clinics, procedures to be employed in an epidemic area, and forms useful in obtaining family and case histories.

Budget Payment Plan of the Nevada State Dental Society. *PHS Publication No. 651; 1959; 18 pages.*

A dental postpayment plan is analyzed to ascertain characteristics of the people who obtain loans to purchase dental care and the nature of the care they purchase.

Sex, age, occupation, family income, and number of persons covered by notes are included in the study of characteristics of the borrower. Frequency of occurrence and expenditures are shown for the various types of dental service provided.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications other than its own.

of mental hospitals but also much greater effort to keep mental and emotional disorders from developing to the point where a mental hospital is the only answer. For this we need many more clinics and other outpatient facilities for the less seriously disturbed and more day-care centers and psychiatric units in general hospitals for those whose conditions require more extensive treatment.

The consensus of those with whom I have discussed this problem appears to be that one of the greatest potentials in the whole field of mental illness lies in earlier diagnosis and earlier intensive treatment.

In this connection, the National Institute of Mental Health is supporting a study to determine the feasibility of incorporating protection against mental illness in voluntary health insurance programs. Such a development, I am convinced, would go a long way toward encouraging people with incipient mental or emotional disorders to obtain competent professional advice and assistance before their ailments reached a serious stage. There have been several instances, I understand, where a few ounces of prevention in the form of intensive early treatment have worked wonders with persons who in the normal course of things probably would have landed in mental institutions.

The great need today is for more professionally trained personnel in all fields of mental health.

The American Psychiatric Association in December 1957 published results of a study of professional staff in public mental hospitals as of 1956. This study shows that the number of physicians, psychologists, registered nurses and other nurses, and attendants was grossly inadequate.

The minimum APA recommendations for physicians in mental hospitals is 1 to every 94 to 98 patients. The actual ratio in 1956 was 1 physician to every 184 patients, or a shortage of 55 percent.

The recommended ratio of clinical psychologists is 1 to every 400 to 500 patients. The actual ratio of 1 psychologist to every 769 represents a shortage of over 35 percent.

The recommended ratio of registered nurses is 1 to every 15 patients. The actual ratio of 1 registered nurse to every 77 patients in 1956 represented a shortage of over 80 percent.

The APA recommends that in addition there be one other staff member (nurse or attendant) to every five patients. The actual ratio of one to every seven patients in 1956 represented a shortage of about 25 percent.

Because of these shortages, I am told that the potentials inherent in the new tranquilizing drugs are as yet largely unrealized. These drugs do not cure mental illness. They are effective in calming disturbed patients to the point where they can be reached with treatment. If the treatment is not available, the effect of the drugs is lost.

The Federal Role in the Nation's Health

ELLIOT L. RICHARDSON

WITH THE EXCEPTION of a flurry of health activities during and after World War I, the Federal Government played a very limited role in family and community health until the thirties. During the First World War, for example, the Public Health Service was authorized to provide extra-cantonment sanitation activities and to inaugurate a venereal disease control program. And when the disastrous influenza pandemic hit the United States in 1918-19, Congress appropriated \$1 million to the Public Health Service to help suppress this disease.

In the postwar period Federal health activities languished. Then the great depression of the early thirties brought the Social Security Act, which prepared the way for wider Federal participation in public health activities. A substantial program of grants-in-aid to the States for general public health purposes was authorized. Later, specialized programs for tuberculosis and venereal disease control were added.

Despite these measures, the Federal investment in public health and medical research was quite meager until World War II. In 1940, for example, a year in which the Federal budget was \$6.2 billion, only \$3 million was spent for medical research and an additional \$19 million for all other health purposes, including grants to the States.

At the onset of World War II, with the mass tragedy of 1918's influenza pandemic far from forgotten, there emerged a realization of the

vital roles that individual and collective health could and would play in the national security. In the early days of World War II the Federal Government quickly recognized that a healthy citizenry was vital to winning the war and that bold approaches to the prevention and cure of disease must have stimulus as well as supplementary financial support.

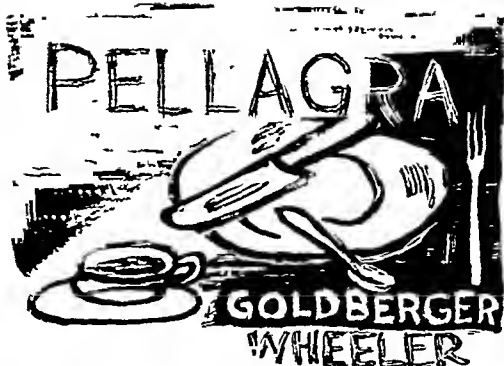

In consequence, the now widely used cooperative approach to medical research was evolved by universities, foundations, industries, and government at local, State, and Federal levels—a pattern that deserves to flourish for a long time to come.

I need not recount the dramatic medical achievements that have resulted from this cooperative approach to research during the past decade and a half. Never before in history has there been such an extraordinary accumulation of new medical knowledge and such a swift advance in technical methods and skills for the application of that knowledge.

As a result, we now have in America a citizenry that is keenly interested in health and generally aware of what is available in medicine. The citizen, the consumer of the medical product, not only expects medical science to go forward at even a faster pace but also insists that the products, techniques, and skills that derive from current achievements be readily accessible to all who need them. Indeed, today the Federal Government is expected to be responsive, to a degree unknown in any former time, to inexorable demands for medical and public health services which no single group acting alone could ever provide and which all groups in concert can barely meet.

At almost every point in the spectrum which has at one end the development of new knowl-

Mr. Richardson, Assistant Secretary of Health, Education, and Welfare, delivered this address May 5, 1959, at the centennial meeting of the Kansas State Medical Society in Topeka, Kans.

EXPERIMENTAL PELLAGRA IN THE HUMAN SUBJECT BROUGHT ABOUT BY A RESTRICTED DIET.

By JOSEPH GOLDBERGER Surgeon, and G. A. WHEELER, Assistant Surgeon, United States Public Health Service

In this communication we present a brief outline, with the results, of an experiment planned to test the possibility of producing pellagra in the healthy human, white, adult male, by a restricted, one-sided, mainly carbohydrate (cereal) diet.

The experiment was carried out at the farm of the Mississippi State Penitentiary, about 8 miles east of Jackson, Miss. At about the center of this farm of some 3,200 acres, well isolated from the surrounding communities is the "camp," consisting of a group of frame buildings, including the cottages of the officials, the "cage," "now hospital," barns, stables, etc. Dr. A. G. McLaurin, the prison physician, informs us that there is no history of the occurrence or presence of pellagra on this farm.

During the period of the experiment there have been quartered at this "camp" an average of between 70 and 80 convicts, all white males. Included in this number were 12 who, accepting the offer of a pardon made them by Gov. Brewer and with the assurance of proper care and treatment should such be needed, volunteered to submit themselves to the experiment. White adult males were selected because, judged by the incidence in the population at large, these would seem to be least susceptible to the disease.

Experiment.

The volunteer squad of 12 men was organized between February 1 and February 4, 1915. On July 1, 1915, one of the volunteers was released because of the development of a prostaticitis. This left 11 men in the squad, 24 to 50 years of age, who have remained in the test, on the prescribed diet, to its termination, October 31, 1915. These men were quartered in the so-called "new hospital building," a small, screened, one-storied cottage, about 500 feet from the "cage" in which the other convicts were domiciled. This cottage had previously been used as the quarters for the "assistant sergeant" of the "camp." From the time of its organization this squad was strictly segregated and under guard day and night.

NOVEMBER 12, 1915, pp. 3336-3339

Dr. Goldberger and Dr. G. A. Wheeler produced pellagra in 6 of 11 men by restricting their diet mainly to carbohydrates. Later, with Sydenstricker (*Public Health Reports*, March 19, 1929, pp. 648-713), they showed a relationship between pellagra and diet lacking in milk and fresh meat.

Apart from their significance in establishing long-range goals, these studies have reinforced our firm belief that research, education, and training are inherently inseparable and that a successful research and training effort for the Nation as a whole must be securely grounded upon a sound educational base. For this reason we are more concerned than ever about the urgency of immediate steps to correct the imbalance between medical research and education that has tended to result from the very magnitude of Federal research expenditures.

Our analysis has, for example, confirmed the view that the National Institutes of Health should pay not only the direct costs of any research project which they support but should also pay whatever share of indirect costs, such as administrative salaries, heat, light and power, and maintenance of buildings, is fairly attributable to that project. Until this is done, each new project undertaken by a medical school will result in an additional drain on its operating funds, thereby weakening its capacity to carry out its teaching mission. Similarly, hospital care will suffer from the diversion of uncommitted income to the support of research. We propose, therefore, at the earliest opportunity, to renew the fight to eliminate the limitation on the payment of indirect costs which for a number of years has been contained in our appropriations acts.

A related problem concerns the very considerable number of medical school and hospital personnel whose salaries are being paid in full or in part out of research grant funds. Under existing law no assurance can be given that such funds will continue to be provided in predictable amounts. The result is that no security of tenure and no firm career ladder in medical research can be offered to the men and women engaged in such projects.

To remedy this and at the same time to make possible a degree of flexibility in the allocation of research funds with a minimum of red tape, we have under consideration recommendations for legislation that would authorize the allotment to the research institution of a percentage of total research appropriations on an "institutional grant" basis. To the extent, in other words, of say 15 percent of such appropriations, we would make allotments among re-

search institutions in a manner that would not require specific project applications and that would enable them to utilize the funds for the continuing work of their senior investigators.

Grants for Professional Training

In conjunction with its projection of future expenditures for medical research, the Bayne-Jones Report warned that the present shortages of professional and technical manpower are likely to grow even more critical as research demands increase. Larger numbers of well-trained professional people are going to be needed not only to conduct the search for new knowledge but to bring this knowledge to our rapidly expanding population in the form of better medical care. Speaking to the latter point, the Bayne-Jones group predicted, "A minimum of 14 or as many as 20 new medical schools will have to be built (by 1970) if the existing number of physicians per 100,000 population is not to fall."

The Public Health Service, with the help of a new advisory group headed by Frank Bane, former executive director of the Council of State Governments, is now systematically studying the whole question of the need for physicians and exploring the ways in which this need may be met. This study, together with the National Institutes of Health study of 20 medical schools and the Bayne-Jones Report, should provide a strong basis on which to develop national goals for medical education and research.

The Federal Government, meanwhile, is already making significant contributions toward the reduction of manpower shortages in the health field. The National Institutes of Health of the Public Health Service, for example, will spend in 1959 more than \$60 million in stipends for individuals preparing for careers in medical research, for the support of traineeships for persons intending to become specialists in one of the fields covered by a categorical institute, in grants to teaching institutions for the support of training courses, and for research fellowships. In addition, the Public Health Service is spending \$57 million for training in water pollution control activities, advanced nursing, and other public health responsibilities.

edge in the health field and at the other the financing of medical care, the Federal Government has already assumed some degree of responsibility. That responsibility now includes participation with official and voluntary State and local agencies in the formulation of research policies in particular areas; the support of that research; aid to professional and technical education and training; assistance in the construction of new facilities and the renovation of old; help in the prevention and control of disease; consultation and funds to help institutions to effect the most fruitful utilization of scientific and teaching faculties; financial aid to improve and expand institutions devoted to research and treatment; and finally, cooperation in strengthening and complementing private and public systems of financing medical care.

We cannot, therefore—even if we were inclined to do so—start from scratch in attempting to frame legislation designed to strengthen the capacity of the Federal Government to assist in dealing with the health problems of today and tomorrow. As we see it, our function is to take such additional action as may be necessary in a manner that will so far as possible preserve and strengthen the pattern of Federal, State, local, and private cooperation that has worked so well in the past. My aim will thus be to show how we in the Department of Health, Education, and Welfare are attempting to apply this approach to the problems in the field of health that seem to us most urgent. In so doing, I shall start with medical research, proceed from there to the needs of medical schools and related teaching institutions, describe our present thinking with regard to medical care facilities, and conclude by touching briefly on the financing of medical care.

Medical Research

Amid all the vast array of urgently needed health, education, and welfare activities, medical research today occupies a favored position. It is the only one of which the sole question asked is, How much can usefully be spent? Although expenditures for medical research still represent only about 4 percent of the Nation's total investment in research and development, such expenditures have more than doubled in

the last 5 years. The Federal Government's share, meanwhile, has gone up by almost 300 percent.

This phenomenal growth in the support of medical science has, of course, been fed by the very achievements of medical science. Each new discovery reinforces the public demand for still faster progress in the conquest of the cripples and killers that are mankind's most ancient enemies. The consequences, however, for medical education and for the private agencies and organizations actively concerned with medical research, as well as for Government, are so significant and far-reaching as to cry out for careful study and evaluation. To make such a study, former Secretary of Health, Education, and Welfare Marion B. Folsom in 1957 appointed a committee of distinguished consultants under the chairmanship of Dr. Stanhope Bayne-Jones, formerly dean of the Yale University School of Medicine and technical director of research, Office of the Surgeon General of the Army. The committee presented its report, now generally referred to as the Bayne-Jones Report, in June 1958.

Over the past 4 months Secretary Flemming has devoted considerable time with the Surgeon General of the Public Health Service and the director of the National Institutes of Health, Public Health Service, and their staffs, to studying the full implications of this report. He has also reviewed the data obtained from a supplementary study of 20 medical schools conducted by the National Institutes of Health.

On the basis of these data it has been possible to project the probable rate of growth in expenditures for medical research and to formulate as a long-range national goal for such research a total annual expenditure of \$1 billion by 1967. We assume, as a guide for national action, that the support of medical research should continue to be divided almost equally between Federal and non-Federal sources. It is expected, moreover, that the present pattern of support within the Federal Government will be generally maintained, with the National Institutes of Health providing most of the Federal share. This would mean an increase in National Institutes of Health expenditures for research from \$209 million in fiscal 1959 to an annual rate of about \$350 million by 1967.

wartime deferment of construction and now because of the population boom, that the Federal Government has for more than 10 years been playing a major part in a nationwide cooperative program designed to meet this need. The Hill-Burton Act, which created the hospital survey and construction program in 1948, has been a tremendous success, particularly in building general hospitals. And yet most of the gain in new beds has been offset by increases in population, by obsolescence, and by the abandonment of old facilities as new facilities are constructed. Like Alice and the Red Queen, we have had to run like blazes to stay in the same place.

Eleven years ago we had about 60 percent of the general hospital beds we needed. Today, with the help of almost \$1 billion in Federal funds and more than \$2 billion in State, local, and private matching funds, 75 percent of the need for general hospital beds has been met. In addition, we now have 73 percent of the tuberculosis beds needed, as compared with 46 percent in 1948. In mental hospital beds we have slipped from 55 percent of the need in 1948 to 53 percent today. All in all, State plans show a remaining deficit of 888,000 hospital beds of all types and 323,000 nursing home beds.

An equally pressing problem has been the rapid upward spiral in the costs of hospital care, more than 179 percent in a decade. The search for means of combating this rise has been a central purpose in the allocation of research and demonstration project funds—\$1,200,000 annually—under the Hill-Burton program. In our view, the results of experimentation in “progressive patient care” are particularly promising. This is a pattern of services making use both of physical facilities and of medical and nursing personnel in the manner best suited to the needs of the individual patient. It includes intensive care for critically ill patients, intermediate care for those requiring a moderate amount of service, self-care in a hotel type of setting for ambulatory patients, and long-term care for the chronically ill in a homelike atmosphere with periodic evaluation of progress and rehabilitation.

Concern with the high cost of hospitalization

also underlies much of our recent thinking with respect to improvements in the Hill-Burton program. In this connection we are laying particular stress on finding ways and means of making the diagnostic and treatment center category of the program more useful. As the Hill-Burton Act now stands, we can make grants for the construction of such centers only where the center is formally affiliated with a hospital. Although we have considered asking for the complete elimination of this requirement, our present view is that it should be removed only for mental health clinics and diagnostic and treatment centers in remote areas.

The limitations of the Hill-Burton Act, however, are not the major barrier to the construction of more facilities for outpatient services. More important is the lack of readily available insurance against the cost of out-of-hospital care and treatment. It is heartening, therefore, that the health insurance industry has this problem under intensive study and has already taken a number of experimental steps toward providing such insurance. In addition to major medical expense insurance, which from its inception has been applicable to the costs of medical care wherever it may be provided, many insurance companies as well as Blue Shield plans now offer coverage against the costs of physicians' services in the home or office. In the meanwhile, we are continuing to search for ways of encouraging faster progress in this direction.

So far as facilities for acute care are concerned, the principal contribution of the Hill-Burton program has been toward the construction of new hospitals. Rural communities altogether lacking in hospital beds have been the chief beneficiaries. Needed in addition, however, is some form of assistance in financing the cost of repair and modernization of existing hospitals in urban areas. Several approaches to meeting this need are possible: earmarked grants, direct low-interest loans, mortgage insurance, or some combination of the three. These approaches are all under study in the Department. In addition, we believe that we should continue to emphasize the importance of experimentation in measures designed to reduce the cost of hospitalization. For this purpose we are considering the merits of expand-

Assistance to Research and Training Institutions

All these programs—research grants, traineeships, fellowships, even training grants—amount in effect, so far as the research or teaching institution is concerned, to payments for the purchase or reimbursement of services. To the extent that such payments are applied to activities that the institution would in any case feel bound to undertake—and certainly a medical school would be obliged to support a certain amount of research even if no Federal grant program existed—they can of course be regarded as aid to the institution. Yet it is equally clear that the research and research-related training programs now being carried out are much larger in volume and different in character than they would be if Federal funds were not available. Indeed, the programs would not be serving their purposes if this were not the case, for they were not designed primarily for the assistance of institutions. Frequently, in fact, as I have tried to make clear in discussing the need for the full payment of indirect costs and for institutional grants, the programs operate as burdens on the institution.

We cannot escape, therefore, the obligation to face squarely the need for more direct forms of Federal assistance to health training and research institutions. For medical schools, dental schools, and schools of public health, particularly, this need is becoming increasingly acute. As President Eisenhower stated in addressing the National Fund for Medical Education a year and a half ago:

The rapid accumulation of new medical knowledge is flooding in like a tide in the Bay of Fundy. There is on all sides a mounting demand for health services by our communities. Under these demands, the medical schools in America today face inherited responsibilities beyond what they are financially able to meet. The medical progress of which we are so justly proud has involved these teaching institutions in a struggle for solvency and survival.

The constantly widening scope and complexity of medical education has, within the space of a few decades, quadrupled the cost of producing a qualified doctor. Tuition now pays but one-fifth of the student's total education cost.

Accordingly, there is—today—a great gap to close: the gap between the ceiling of medical school receipts from all sources and the racing increase in costs of teaching, research, and medical care.

Under present law the only Federal program

that provides direct help to medical schools and kindred institutions is the program of matching funds for the construction of research facilities. First enacted in 1956 and extended in 1958 until 1961; this program authorizes expenditures up to \$30 million a year for buildings used in the actual conduct of research, or for that part of a building to be devoted to research, but not for buildings or parts of buildings used for teaching or administration. Although authority to make grants for the latter purpose has been advocated by the Administration in each of the last 3 years, Congress has not yet seen fit to grant it. Budgetary considerations permitting, we shall probably try again. Next time, however, we may modify our earlier proposals by suggesting that grants be restricted to buildings needed in order to expand enrollments or to prevent their reduction.

So far as outright Federal grants for operating purposes are concerned, the only beneficiaries at the present time are the 11 schools of public health. In recognition of the fact that most of their graduates enter public service, Congress passed a bill in 1958 authorizing grants to these schools in an aggregate amount of \$1 million a year. The act was limited to 2 years in duration and therefore expires in 1960. Assuming that it is to be extended, should it be confined to the schools of public health, be modified so as to restrict it to the support of special projects in public health training, or be expanded to include other types of teaching institutions in the health field? Should its significance as a precedent, in other words, be ignored, brought more nearly into line with the National Institutes of Health training grant programs, or extended? Most of us in the Department of Health, Education, and Welfare, especially those of us who have been wrestling with the needs of higher education as a whole, would hesitate long before recommending simple extension.

Aid to Institutions Providing Patient Care

New weapons in the war against disease and training in their use are of little avail if we lack the facilities in which to employ them in caring for the sick. So great has been the need for such facilities, first as a result of the

average medical care needs. As a group they use about two and a half times as much general hospital care as the average for persons under age 65, and they have special need for long-term institutional care. Their incomes are generally considerably lower than those of the rest of the population, and in many cases are either fixed or declining in amount. They have less opportunity than employed persons to spread the cost burden through health insurance. A larger proportion of the aged than of other persons must turn to public assistance for payment of their medical bills or rely on "free" care from hospitals and physicians. Because both the number and proportion of older persons in the population are increasing, a satisfactory solution to the problem of paying for adequate medical care for the aged will become more rather than less important.

In our society the existence of a problem does not necessarily indicate that action by the Federal Government is desirable. The basic question is: Should the Federal Government at this time undertake a new program to help pay the costs of hospital or medical care for the aged, or should it wait and see how effectively private health insurance can be expanded to provide the needed protection for older persons?

The report itself does not attempt to answer this question, although it sets forth the arguments on both sides. Building on the data contained in the report, we are now trying to develop an answer. It is not an easy task, and I would not venture to predict where we will come out. One thing, however, is sure: before reaching any final conclusion we will seek opportunities for consultation with representatives of the medical profession and other interested groups. This approach has helped to solve many health problems in the past, and we are confident that it will lead us to a sound solution of this one also.

As the President has eloquently declared:

A healthy citizenry is the first defense line of the Republic. A healthy citizenry is capable, in peacetime, of expanding our economy; in times of critical tension, of carrying on without cracking or growing hysterical; in times of conflict, of showing the endurance and stamina upon which victories are built.

Salaries of Local Public Health Workers

Salaries of local public health workers continued to increase between 1954 and 1958, but at a progressively lower rate than in the previous 2 years, according to the latest survey. The study, the sixth since 1948, was sponsored by the Public Health Service, the American Public Health Association, the Association of State and Territorial Health Officers, and the National League for Nursing.

Except for dentists and some sanitation personnel, the increase in median salaries from 1954 to 1958 ranged from 13 percent to 24 percent in local health units serving populations of 50,000 to 249,999.

The highest rate of increase for 6 of the 12 occupational groups studied—local health officers (medical), sanitary engineers, other sanitation personnel, professional laboratory workers, clinic nurses, and staff public health nurses—was in health units serving popula-

tions of 250,000 to 499,999. For the other six groups—other public health physicians, dentists, sanitarians, veterinarians, health educators, and supervising public health nurses—the highest rate of increase was in units serving populations of 500,000 and over.

The rates of salary increases were less uniform in the largest health units than in the smallest.

Data for 10-year comparisons are available for units in the 50,000-to-249,999 population class. Since 1948, the greatest increase, 74 percent, has been for local health officers and the next greatest, 73 percent, for sanitary engineers. No decrease was recorded for any category of public health workers.

Data are reported in "Salaries of Local Public Health Workers, August 1958," Public Health Service Publication No. 656. (See announcement of publication on p. 752.)

ing the research and demonstration authority of the Hill-Burton program so as to provide for direct grants—grants, in other words, not included in State allotments—for the building of experimental structures.

One other amendment to the Hill-Burton program that we expect to propose is motivated both by the aim of avoiding unnecessary hospitalization in high-cost institutions and by awareness of the continuing increase in the number of the aged. This amendment would consolidate the chronic-disease hospital and nursing-home categories of the program into a new "long-term care facilities" category and increase the authorized appropriations for this category. For similar reasons we also support the provision in the pending housing bill of mortgage insurance for proprietary nursing-home construction, with assurance through State licensing agencies of adequate standards of care.

Disease Prevention Programs

Disease prevention programs are fundamental activities of the Public Health Service in cooperation with State and local health departments. Although the acute communicable diseases have declined in prevalence, keeping them under control requires unrelenting vigilance. Yet the very success of public health techniques in curbing the acute contagions has been accompanied by a steady rise in the chronic diseases, especially those of the heart and arteries, cancer, diabetes, and the debilitating disorders peculiar to old age. Research and epidemiological investigations into their causes, incidence, and cure are being conducted on a wide scale. So far as prevention is concerned, the greatest unmet need is in health education. Our efforts in this direction need intensification, and, if possible, the application of more vigor and imagination.

High priority among preventive health activities must also be given to the problem of maintaining a healthful physical environment. Modern technology, urban growth, and industrialization are daily making this problem more acute. Water pollution, waste disposal, food and drug contamination, smoke and smog, and nuclear fallout present hazards to health

whose seriousness is not yet fully known. Radiation hazards in particular demand a comprehensive approach, and the Budget Bureau now has under study the relative responsibilities of the Public Health Service and the Atomic Energy Commission in this field. In addition, we in the Department of Health, Education, and Welfare are considering the possible need for some form of assistance to the States in the exercise of their radiological health responsibilities.

Financing the Costs of Medical Care

Even after new knowledge has been won, doctors have been trained, facilities have been built, and everything possible has been done to prevent disease, there remains the problem of paying for medical care. Although we have reached new heights of prosperity in the United States, medical costs represent a serious problem to many American families. In 1957, for example, about half of all the families in this country had incomes below \$5,000 and one family in seven had an income below \$2,000. As many as one-quarter of all American families today have no cash savings, and in 1958 it was estimated that more than half of our families had savings of less than \$500. For these people the costs of long-term and other disabling illness can be a crushing burden, particularly if the victim is the breadwinner.

For most people voluntary health insurance represents the best means of meeting the costs of medical care. Preliminary estimates for December 1958 show that just over 121 million people, or 70 percent of the population, then had some form of hospital insurance. Ten years earlier, in December 1947, the 53 million persons with such protection represented 37 percent of the total population.

There are, however, serious gaps in coverage of our older citizens, less than half of whom have any kind of health insurance. Summarizing an intensive study of this subject for the House Committee on Ways and Means, the Department of Health, Education, and Welfare last month reported:

There is general agreement that a problem does exist. The rising cost of medical care, and particularly of hospital care, over the past decade has been felt by persons of all ages. Older persons have larger than

average medical care needs. As a group they use about two and a half times as much general hospital care as the average for persons under age 65, and they have special need for long-term institutional care. Their incomes are generally considerably lower than those of the rest of the population, and in many cases are either fixed or declining in amount. They have less opportunity than employed persons to spread the cost burden through health insurance. A larger proportion of the aged than of other persons must turn to public assistance for payment of their medical bills or rely on "free" care from hospitals and physicians. Because both the number and proportion of older persons in the population are increasing, a satisfactory solution to the problem of paying for adequate medical care for the aged will become more rather than less important.

In our society the existence of a problem does not necessarily indicate that action by the Federal Government is desirable. The basic question is: Should the Federal Government at this time undertake a new program to help pay the costs of hospital or medical care for the aged, or should it wait and see how effectively private health insurance can be expanded to provide the needed protection for older persons?

The report itself does not attempt to answer this question, although it sets forth the arguments on both sides. Building on the data contained in the report, we are now trying to develop an answer. It is not an easy task, and I would not venture to predict where we will come out. One thing, however, is sure: before reaching any final conclusion we will seek opportunities for consultation with representatives of the medical profession and other interested groups. This approach has helped to solve many health problems in the past, and we are confident that it will lead us to a sound solution of this one also.

As the President has eloquently declared:

'A healthy citizenry is the first defense line of the Republic. A healthy citizenry is capable, in peacetime, of expanding our economy; in times of critical tension, of carrying on without cracking or growing hysterical; in times of conflict, of showing the endurance and stamina upon which victories are built.

Salaries of Local Public Health Workers

Salaries of local public health workers continued to increase between 1954 and 1958, but at a progressively lower rate than in the previous 2 years, according to the latest survey. The study, the sixth since 1948, was sponsored by the Public Health Service, the American Public Health Association, the Association of State and Territorial Health Officers, and the National League for Nursing.

Except for dentists and some sanitation personnel, the increase in median salaries from 1954 to 1958 ranged from 13 percent to 24 percent in local health units serving populations of 50,000 to 249,999.

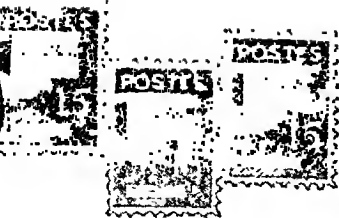

The highest rate of increase for 6 of the 12 occupational groups studied—local health officers (medical), sanitary engineers, other sanitation personnel, professional laboratory workers, clinic nurses, and staff public health nurses—was in health units serving popula-

tions of 250,000 to 499,999. For the other six groups—other public health physicians, dentists, sanitarians, veterinarians, health educators, and supervising public health nurses—the highest rate of increase was in units serving populations of 500,000 and over.

The rates of salary increases were less uniform in the largest health units than in the smallest.

Data for 10-year comparisons are available for units in the 50,000-to-249,999 population class. Since 1948, the greatest increase, 74 percent, has been for local health officers and the next greatest, 73 percent, for sanitary engineers. No decrease was recorded for any category of public health workers.

Data are reported in "Salaries of Local Public Health Workers, August 1958," Public Health Service Publication No. 656. (See announcement of publication on p. 752.)

Snail Inhibitor

Evidence that the algae characeae inhibit the snail host (*Australorbis glabratus*) of schistosomiasis was reported in Brazil, where an estimated 6 million persons are parasitized. Lair Remusat Rennó, professor of botany of the University of Minas Gerais, stated that during 6 years of research, the snails have not been observed in water courses containing the algae characeae (*Chara vulgaris*). After the algae were seeded in heavily infested areas, the snails disappeared within a short time. Research is underway to isolate the property which repels snails.

The findings were reported at the third national seminar of sanitary engineering professors, sponsored by the Ministry of Education, the University of Minas Gerais, Serviço Especial de Saúde Pública, and the U.S. Operations Mission in Brazil, at Belo Horizonte in July 1958.

—E. ROSS JENNEY, M.D., chief, Health and Sanitation Division, U.S. Operations Mission, Brazil.

The Early Rains

Last October severe regional outbreaks of malaria occurred in Ethiopia in areas with elevations of 5,000 to 6,500 feet. We received a warning early in June when a malaria survey in the Bahar Dar area, which has an elevation of 6,000 feet, revealed an exceptionally high prevalence of malaria in many villages which ordinarily would be free of the disease until much later in the season. Unusually early rains there had produced large populations of *Anopheles gambiae*.

Checks in some of the epidemic areas showed infections almost exclusively with *Plasmodium falciparum*.

The severity of the epidemics so alarmed some local officials and provincial governors that they appealed to the Emperor for drugs, insecticides, and

medical personnel. Anti-epidemic teams were organized by the Ministry of Health and dispatched to the stricken areas.

—ROBERT D. SHANNON, acting chief, Health and Sanitation Division, U.S. Operations Mission, Ethiopia.

Practical Nurses

The new 8-month course for nurse assistants, needed to relieve the shortage of nurses in Vietnam, will be well attended. Two thousand applied for the 60 openings for students in Saigon and 400 for the 40 vacancies in Hue. Half the students selected for the first course were men and half were women. They will wear a blue and white uniform during their training.

We hope that this course, which is similar to the training for practical nurses in the United States, and the new 3-year course for professional nurses will help standardize the classification of this profession into 2 clear-cut groups instead of the present 30 vague and overlapping categories.

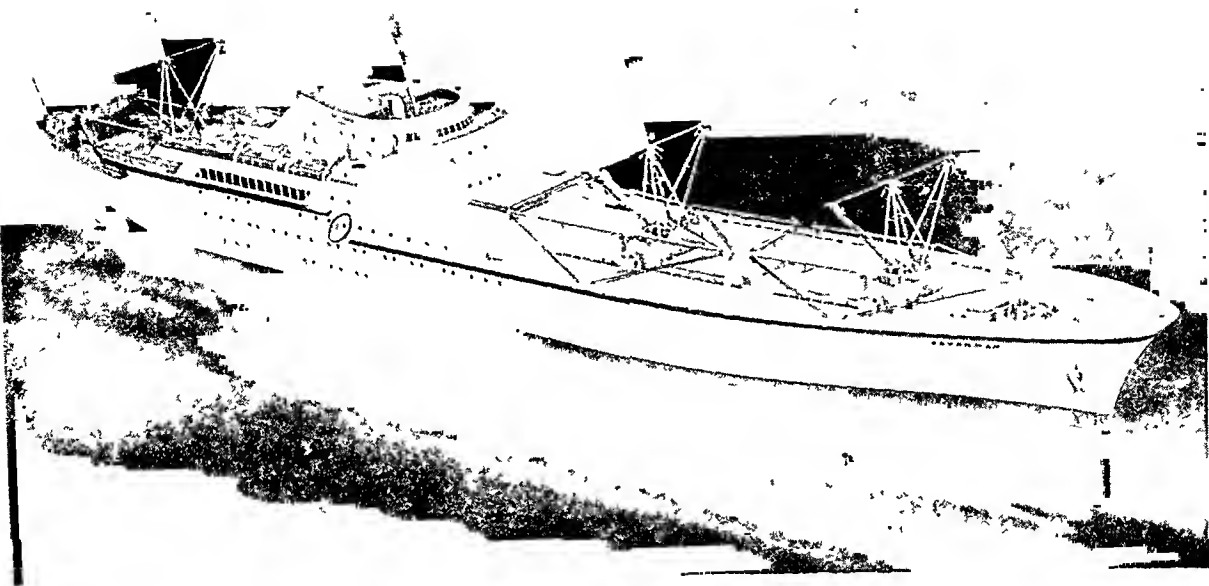

—WILLARD H. BOYNTON, M.D., chief, Health and Sanitation Division, U.S. Operations Mission, Vietnam.

Milk and Water

On a visit to an isolated Arawak village, a center for some 500 Amer-Indians living in this area of Surinam, we examined practically all of the infants and toddlers and the 30 school children. Their nutritional status was relatively good because of the powdered milk they receive from UNICEF. Inflammation of the eyes was the only easily recognizable affliction of high prevalence. We were not sure what percentage was trachoma and what follicular conjunctivitis, as both appeared to be present.

The Amer-Indians frequently asked for more ophthalmic ointment for their eyes, but rarely, however, as we toured the area, did anyone mention that the community needed a well. Daily the small children carry to their homes a few buckets of water from a creek 1½ kilometers distant, the nearest year-round source.

—HILDRUS A. POINDEXTER, M.D., former chief public health physician, U.S. Operations Mission, Surinam.

Safety on the Nuclear Ship Savannah

RICHARD P. GODWIN, B.S., PRESTON P. EDDY, B.S., and RALPH K. LONGAKER, M.S.

THE LAUNCHING of the *NS Savannah* in July 1959 signaled a major advance in the peaceful application of nuclear energy. Following outfitting, tests, and sea trials, the *Savannah* is expected to enter the sealanes of the world during 1960, powered by a nuclear reactor which will not require refueling for 2 to 3 years. Safety, both nuclear and marine,

Mr. Godwin is assistant director for maritime reactors in the Division of Reactor Development, Atomic Energy Commission, and nuclear projects officer for the Maritime Administration, Department of Commerce. Mr. Eddy is project manager in charge of design, engineering, and construction for the NS Savannah. Mr. Longaker, a sanitary engineer with the Special Projects Branch, Division of Radiological Health, Public Health Service, is now on detail as Public Health Service liaison to the Maritime Administration-Atomic Energy Commission nuclear-powered ships projects.

has been the keynote throughout the project in design and construction and in planning the vessel's operating program.

The nuclear-powered ship is the second *Savannah* to make maritime history. One hundred and forty years ago, a 320-ton wooden ship with all sails set on her three masts and belching smoke from a funnel amidship, commenced an epoch-making voyage from Savannah, Ga., to Liverpool, England. She was the *SS Savannah*, the first vessel to use steam on a transatlantic crossing. The 29-day voyage was successful even though only enough coal and wood could be carried to permit about 80 hours of steaming. Captain Moses Rogers, skipper of the vessel, stopped briefly at Kinsdale, Ireland, to replenish his fuel supply so that he could make a spectacular arrival by steaming up the Mersey River to Liverpool under power. However, the watch in the coastal station at Cape Clear on Ireland's south-

ern tip sighted the *Savannah* with smoke coming from her stack and concluded she was on fire.

The British revenue cutter *Kite* was sent to her relief. To the surprise of the cutter's crew, the *Savannah*, without a sail set, outdistanced them completely. It was not until after the exasperated crew of the *Kite* had fired a shot across the bow of the American vessel that she stopped and gratified their curiosity.

Thus, the *SS Savannah* ushered in the steam age in ocean travel. Today another *Savannah*, bearing the designation "NS," will usher in the atomic age.

Development

On April 25, 1955, President Eisenhower first suggested the construction of a nuclear-powered merchant ship which, visiting the ports of the world, would demonstrate to people everywhere the peacetime use of nuclear energy, harnessed for the improvement of human living.

The following year, Congress passed legislation which made construction of the ship possible, and on October 15, 1956, the program was initiated. A joint group, drawing its members from the Maritime Administration of the Department of Commerce and from the Atomic Energy Commission, was established to administer the program.

Shortly thereafter, the U.S. Coast Guard, the Public Health Service, and other Federal agencies began to assist the nuclear merchant ship program through assignment of liaison personnel and active participants to technical committees dealing with questions and problems which had no precedent. In addition, the Atomic Energy Commission's Advisory Committee on Reactor Safeguards independently reviewed reactor construction and operating procedures with a view toward the safety of the ship's crew and passengers and the public.

The *NS Savannah* was launched on July 21, 1959. Before the beginning of the comprehensive test program, she will require approximately 7 months of dockside outfitting. Sea trials are scheduled to start during the spring of 1960. To staff the vessel, two groups of specially selected licensed merchant marine officers are being trained in a 15-month course

which includes classroom work in reactor theory, operation of the *Savannah* reactor console simulator, and practical experience at other reactor sites such as those at Hanford, Wash., and Arco, Idaho.

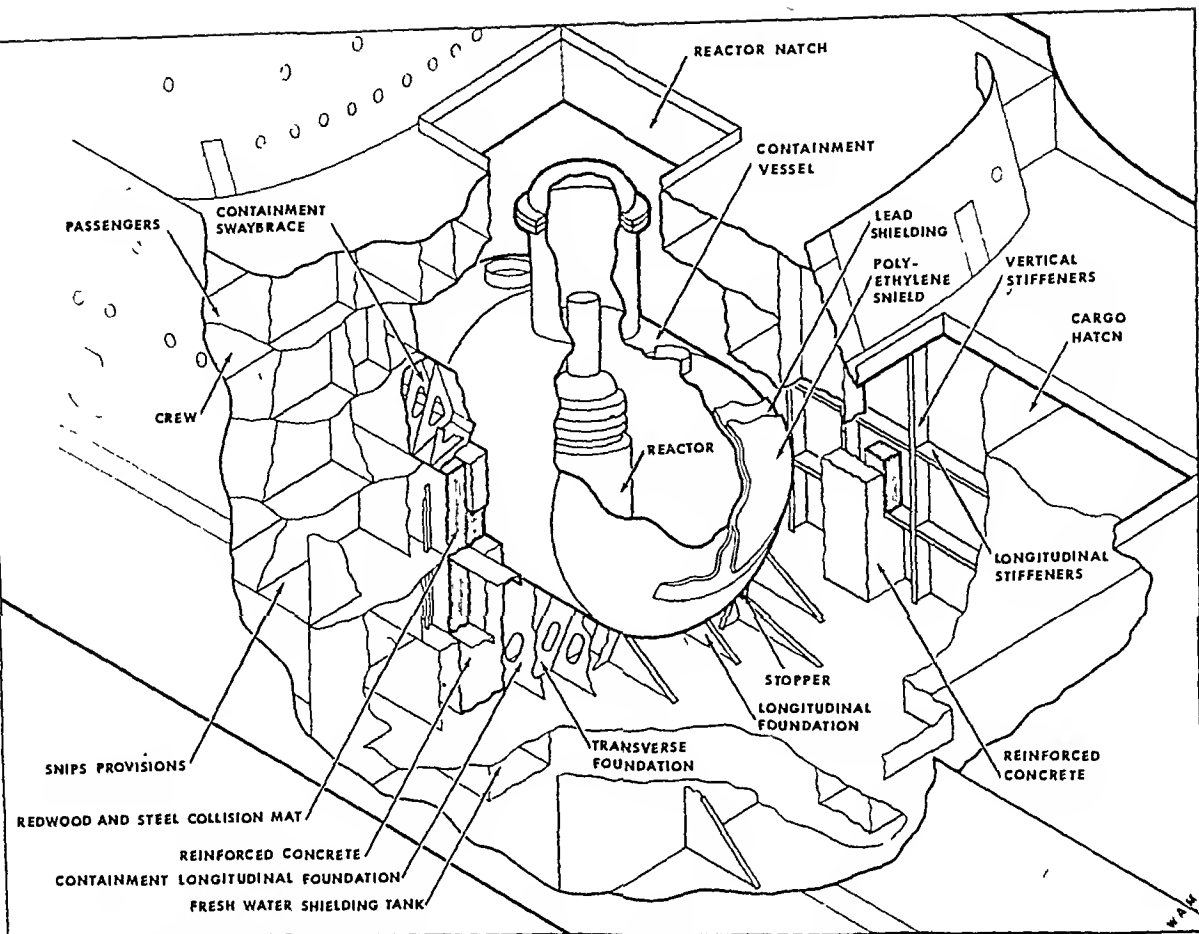

The *NS Savannah* is a combination passenger-cargo ship of the Mariner class. It is 395 feet long, has a 78-foot beam, and will have fully loaded displacement of 21,800 tons. The ship will have a sea speed of 20 knots and a cruising radius in excess of 100,000 miles. With a 124-man crew and additional space for observers and technicians, she will also be able to carry 60 passengers.

The nuclear plant, including the containment vessel, shielding, and propulsion machinery are located amidship (see chart). The propulsion power will be provided by a pressurized water reactor operating at approximately 1,750 pounds per square inch at an average temperature of 508° F. The slightly enriched (4.4 percent) uranium oxide core is in the form of a cylinder 62 inches in diameter and 66 inches high. Reactor control is provided by 21 boron stainless steel control rods inserted in channels between the 32 symmetrically arranged fuel elements. The first core has been designed for a maximum power level of 69 megawatts and is expected to produce approximately 52,200 "megawatt-days." In other words, it will have an operating lifetime of about 3 years' normal operation without refueling.

Safety on Nuclear Merchant Ships

The principal problems in ship design introduced by nuclear propulsion are those related to safety, that is, protection of the environment from radioactive contamination. The safety of the ship, the personnel aboard, and the operating environment had to be and were considered for conditions without precedent.

Containment. One of the basic safety problems of a nuclear reactor is the control of fission products. To provide this control it was decided to install the entire reactor system and its major auxiliary components within a shielded containment vessel capable of confining the mechanical energy released in the event of a severe rupture of the "primary" portions of the

Amidship cross section of NS Savannah showing nuclear plant and shielding.

system. Thus, the containment vessel surrounds all of the primary system, preventing the escape of radioactive material and serving as structural protection for the reactor.

The containment vessel, already installed in the ship, is a welded steel cylinder 2½ inches thick, 50 feet long, and 35 feet in diameter. It will be hermetically sealed at all times during plant operation. Television cameras within the vessel will enable the crew to observe conditions from the externally located control room while the reactor is operating. After shutdown of the plant, the containment vessel may be entered through an airlock for inspection and maintenance. Once operating reliability has been demonstrated on the *Savannah*, an expensive, heavy containment vessel of this type may not be necessary on other nuclear merchant ships.

Shielding. A most important feature of the *Savannah* is the radiation shielding. The main

source of radiation during operation of the ship's power plant is the reactor itself. In addition, minute quantities of impurities and also traces of corrosion products remaining in the demineralized "light" water used as primary coolant will become activated while passing through the reactor. However, a bypass purification system will remove these activated materials automatically by ion-exchange methods.

The following conditions had to be met for areas accessible to passenger and crew:

- In all areas to which passengers have access, the radiation level will be less than that required to produce an integrated total body dosage of 0.5 rem per year. This is a conservative figure since it will be determined at the points of highest radiation, and the computations for the annual dosage will be based on the assumption that a person remained in these areas for an entire year. Allowing for movement aboard ship and taking distance from the reactor

into account, the average exposure received by any passenger remaining aboard for a year would probably be less than 0.2 rem—comparable to levels which would be received on land from background and cosmic radiation. In determining these radiation levels, the average annual reactor power has been computed to be approximately 50 megawatts.

- In all areas where crew members have unlimited access, radiation levels will be less than 5 rem integrated dosage per year. This dose limit is in accordance with the guidelines of the International Commission on Radiation Protection and of the National Committee on Radiation Protection. Since the 5-rem area is relatively small and not in general use and since no crew member will be aboard the ship a full year, it is doubtful whether any crew member will receive an annual integrated dosage of more than 0.5 rem in a year.

- Only officers and crew of the engineering department will be allowed access to the controlled machinery spaces aft of the reactor compartment. Other ship personnel will not be permitted in these spaces except under specific authorization of the captain. The engineering crew will be limited to an integrated dosage well within the guidelines of the NCRP and ICRP and will, of course, be equipped with appropriate personnel dosimeters.

- A health and safety staff will continually analyze the environs of the ship to assess and minimize exposure to radiation and control potential hazards.

- Certain areas in the vicinity of the reactor will be denoted as "limited access areas" and will not normally be entered when the reactor is operating. Those areas located outboard of the reactor compartment include the fan room and lockers for storage. At full reactor power, a radiation level of 1 rem per 168-hour week will be the maximum permissible in these areas. They will remain locked at all times, and the captain's permission will be needed for controlled entry while the reactor is at full power.

- The entire secondary shield, surrounding and encasing the containment vessel will, when completed, weigh more than 1,600 tons. "Ordinary" concrete, in the form of a vertical 4-foot thick "skirt" extending up to the "equator" of the vessel, accounts for 1,600 tons, and the 14-inch layer of lead and polyethylene encasing the upper half of containment accounts for 500 long tons.

Waste management. The basic plan for the collection and handling of radioactive waste aboard the *Savannah* is predicated on complete retention of all solid, liquid, and high-activity gaseous wastes. Remotely handled and stored, these wastes will be held in special tanks for periodic dockside transfer. Ultimate disposal by licensed contractors will be based on procedures used for land-based reactor wastes.

Additional safeguards. The reactor system as well as the ship has been designed to minimize the effects of marine hazards such as storm, grounding, fire, flooding, and sinking. In some respects a nuclear ship may be safer than a "conventional" vessel. For example, the fire hazard in the *Savannah's* engine room is considerably less because of the general reduction in oil piping and hot surfaces and the absence of oil-fired boilers.

With respect to the effects of collision, a recently completed study of marine casualties has shown that on the basis of tonnage and speed not one ship in 95 percent of the world's merchant fleet could penetrate the hull of the *Savannah* to the depth of the laminated steel and redwood collision mats placed on the flanks of the containment vessel (see chart).

The probability of ships in the remaining 5 percent colliding with the *Savannah* and penetrating the containment vessel is currently being evaluated. Large ships generally operate at a reduced speed within and when approaching harbor areas. At these speeds, even the larger ship could not penetrate the containment vessel if it were to strike directly at the reactor compartment. As an illustration, citing the 1956 collision of the *Stockholm* and the *Andrea Doria*, it has been determined that the striking ship would have had to travel 1 to 4 knots faster than her maximum speed to penetrate the *Savannah* even to the collision mat.

If collision leading to eventual sinking should occur, the reactor would be "scrapped," that is, shut down automatically. Cooling of the reactor would be continued by the primary circulation pumps operating on emergency power as long as the ship was afloat. If the vessel were to sink in shallow water, the containment vessel would remain intact, and the exposed surface afforded by the vessel would be sufficient to dissipate residual "decay" heat by natural convection. However, if sinking were to occur in deeper water, where the submergence pressure might cause collapse of the containment vessel, automatic flooding valves would open to admit sea water into the vessel to equalize the internal and external pressure on the vessel. (As soon as the internal pressure was equalized, the check-type valves would automatically close.) The pressure equaliza-

tion, by preventing rupture of the containment vessel, would keep the reactor system intact, thus preventing the escape of radioactive elements. Should an accident by any chance open the reactor core, the consequences would be influenced by the stage of the 3-year fuel cycle.

Potential

The construction of the *Savannah* has posed some new and unique problems. For most of them, satisfactory design and operating solutions have been found; the remainder are under study. Complete containment, retention of wastes, and other safeguards, both nuclear and nautical, have been incorporated to achieve maximum safety. The *Savannah's* experimental years of service may show that less stringent requirements will be necessary in the future.

During the past decade there has been an ever-increasing interest in the application of nuclear power in industry, both to conserve existing fuel resources and to provide an additional energy source. Today other maritime nations are actively conducting programs for

the development of nuclear-powered merchant ships. The potential economic advantages of nuclear power over conventional fuels are great; among these are:

- Elimination of the space and weight requirements for fuel oil, resulting in increased cargo-carrying capacity.
- Longer range, making nuclear ships virtually independent of refueling time losses.
- Operation at speeds higher than those now economically feasible for ships powered by the "fossil fuels."

The *NS Savannah*, however, will not be and is not intended to be economically competitive with conventionally fueled merchantmen. Rather, this "first generation" nuclear-powered merchant vessel will be used to provide a baseline of practical construction and operating experience necessary for application to the design of "second" and "third generation" ships. These, in turn, may attain competitive status within the next decade. Thus, the *NS Savannah* is heralding the transition from fossils to fission, quite as her famous namesake crossed the threshold from sail to steam.

Impairments in the United States, July 1957-June 1958

About 24 million impairments, including chronic or permanent physical defects, existed among the civilian, noninstitutional population of the United States during the year beginning July 1, 1957. This figure, published in a report by the U.S. National Health Survey, Public Health Service, is derived from household interviews with a representative population sample and represents a rate of 141.4 impairments per 1,000 noninstitutionalized persons.

The report, "Impairments, by Type, Sex, and Age, United States, July 1957-June 1958," does not indicate the total number of persons with impairments (since many have more than one impairment) except for conditions such as visual, auditory, or speech defects, mental retardation, cerebral palsy, and absence of extremities.

Rates for specific impairments per 1,000 persons were 5.7 for inability to read ordinary newsprint even with glasses; 12.3 for less severe visual impairments; 0.6 for total deafness; and 33.9 for other hearing defects.

Conditions reported frequently were paralysis and other defects of the limbs, back, and trunk, and impaired speech.

Impairments caused by injury amounted to 33 percent of the total; 41.8 percent for males and 22.2 percent for females. Loss or defects of extremities had the highest proportions due to injuries, and speech defects and blindness, the least. Impairments increased from 52.9 per 1,000 persons at ages under 25 years to 615 at ages 75 and over. (Announcement of publication appears on p. 752.)

A proposed standard method of **Measuring Hospital Capacity**

BY A. LEMBCKE, M.D., M.P.H., DAVID R. HERMANSEN, M.A.,
and ELEANOR POLAND, Ph.D.

A STANDARD method of determining bed capacity and the adequacy of space in basic departments is necessary in judging the extent to which hospital needs are being met by existing and proposed buildings.

Hospital needs and resources have traditionally been expressed in terms of beds, which by definition include facilities for both adults and children, but not bassinets for the newborn in a nursery, beds in labor rooms and in health centers, and beds used exclusively for emergency purposes. This definition is incomplete, however. Should the count represent the situation on some one day or throughout the year? Should it be the maximum number or the average? These and many related questions have been resolved by the adoption of uniform definitions required for hospital operation and finance, but others have not, especially in the field of hospital survey and planning.

Another consideration is whether the hospital beds that have been enumerated are acceptable in respect to safety and efficiency.

Dr. Lembcke is professor of preventive medicine and public health, School of Medicine and School of Public Health, University of California, Los Angeles. Mr. Hermansen is assistant professor of architecture, University of Kansas. Dr. Poland is project director, Regional Health and Hospital Study, Community Studies, Inc., Kansas City, Mo. This investigation was partially supported by a research grant from the Division of Hospital and Medical Facilities, Bureau of Health Services, Public Health Service.

The most important points to be considered in determining the acceptability of a structure are fire hazards, structural materials, exit facilities, physical condition, location, suitability of design, and adequacy of space in the essential departments.

Generally accepted methods are now available to determine the fire-resistive properties of existing and proposed hospital buildings and structural materials, and the type, number, and location of exit facilities. The physical condition of a hospital is largely a subjective determination, and the same is true of location except where it is regulated by law.

The suitability of design has many subjective elements, such as the location of the various essential departments and the proportion of beds in one-bed, two-bed, and four-bed rooms. It also has a number of objective features, such as whether the building was originally designed as a hospital, the width of doors and corridors, and the minimum and maximum number of beds in a nursing unit. But these are not included in the method we are proposing for use in measuring hospital capacity because the suitability of design as applied to existing structures is more closely related to the concept of "replaceable" bed capacity, than it is to "unsuitable" bed capacity. By "replaceable" bed capacity we mean rooms and departments that are now included in existing bed capacity but that would be differently designed when their physical condition required replacement by new construction. In such authoritative hos-

pital surveying and planning as that under the Federal Hospital Survey and Construction (Hill-Burton) Act, "unsuitable" beds are not counted in determining the needs for new construction.

Importance of Adequate Space

Safety. Since 1942, when 491 persons died in the Coconut Grove fire in Boston, most State and local governments have recognized the necessity of limiting the occupancy of a theater, restaurant, school, or other public place to the number of people who can be allowed in a given space without endangering their lives in case fire or other accidents require that the premises be vacated quickly. Enforcement requires that the maximum number of persons who can occupy such places with safety be determined by reference to standards based on the space available. This principle has not been fully recognized for hospitals, although they present the additional hazards of cross-infections, of mistakes in the distribution of medicines, and other misadventures that may be aggravated by crowding and inadequate space. Cross-infections are typified particularly by the staphylococcal diseases held responsible for many complications and deaths today.

Efficiency. Adequate space for the essential departments of the hospital is as closely related to efficiency in hospitals as it is in the operation of any other institution or service, mercantile or industrial.

Rooms for patients. Modern medical and nursing care call for sufficient space around the bed to permit many procedures to be carried out in the patient's own bed in his own room. Blood transfusion, intravenous administration of fluids and medicines, the use of indwelling catheters and tidal drainage of body fluids and excretions, administration of oxygen, and decompression of the intestine by the Wangenstein apparatus are examples. Even beds must be longer to accommodate the increasing stature of the American people!

Departments. The safety and efficiency of a hospital may be impaired if one or more departments are not in proportion to the others. This occurs most commonly when beds are

added to the nursing department without adding in like proportion to the administration, pathology, radiology, pharmacy, surgery, obstetrics, emergency, dietary, laundry, house-keeping, and mechanical departments or to the facilities for employees and central storage.

Other factors. As noted earlier, space is not the only criterion of suitability, and an area or department must be judged unsuitable if it is unsafe, regardless of the adequacy of its space. However, an area that is suitable in respect to safety factors may be definitively unsuitable if it falls short of meeting minimum space requirements.

General Method

Our method of determining hospital capacity requires that all the rooms or units of space in a hospital be measured, classified as to function, and allocated to the appropriate hospital departments. The areas so determined are then compared with nationally recognized standards of space for such departments. This method presents consistent, objective criteria of the sufficiency or deficiency of each department and of the hospital as a whole. A given hospital may be found deficient in respect to the rooms for patients, the adjunct diagnostic and treatment facilities, and the administrative and service areas, or it may measure up in all respects, or, as is more common, it may meet standards for patients' rooms but not for other departments. The method is sufficiently flexible to accommodate the use of different standards as desired or as they change with advances in medical care.

Definitions of Hospital Bed Capacity

To avoid confusion it is necessary in every instance to distinguish between the three importantly different meanings of hospital bed capacity—bed complement, normal bed capacity, and potential bed capacity.

The terms "normal" and "potential" bed capacity were used by the Commission on Hospital Care in the schedules of information (1) to be gathered in determining hospital capacity, although a discussion of these terms was not included in its published reports (2, 3).

a proposed standard method of

Measuring Hospital Capacity

PAUL A. LEMBCKE, M.D., M.P.H., DAVID R. HERMANSEN, M.A.,
and ELEANOR POLAND, Ph.D.

A STANDARD method of determining bed capacity and the adequacy of space in basic departments is necessary in judging the extent to which hospital needs are being met by existing and proposed buildings.

Hospital needs and resources have traditionally been expressed in terms of beds, which by definition include facilities for both adults and children, but not bassinets for the newborn in a nursery, beds in labor rooms and in health centers, and beds used exclusively for emergency purposes. This definition is incomplete, however. Should the count represent the situation on some one day or throughout the year? Should it be the maximum number or the average? These and many related questions have been resolved by the adoption of uniform definitions required for hospital operation and finance, but others have not, especially in the field of hospital survey and planning.

Another consideration is whether the hospital beds that have been enumerated are acceptable in respect to safety and efficiency.

Dr. Lembcke is professor of preventive medicine and public health, School of Medicine and School of Public Health, University of California, Los Angeles. Mr. Hermansen is assistant professor of architecture, University of Kansas. Dr. Poland is project director, Regional Health and Hospital Study, Community Studies, Inc., Kansas City, Mo. This investigation was partially supported by a research grant from the Division of Hospital and Medical Facilities, Bureau of Medical Services, Public Health Service.

The most important points to be considered in determining the acceptability of a structure are fire hazards, structural materials, exit facilities, physical condition, location, suitability of design, and adequacy of space in the essential departments.

Generally accepted methods are now available to determine the fire-resistive properties of existing and proposed hospital buildings and structural materials, and the type, number, and location of exit facilities. The physical condition of a hospital is largely a subjective determination, and the same is true of location except where it is regulated by law.

The suitability of design has many subjective elements, such as the location of the various essential departments and the proportion of beds in one-bed, two-bed, and four-bed rooms. It also has a number of objective features, such as whether the building was originally designed as a hospital, the width of doors and corridors, and the minimum and maximum number of beds in a nursing unit. But these are not included in the method we are proposing for use in measuring hospital capacity because the suitability of design as applied to existing structures is more closely related to the concept of "replaceable" bed capacity, than it is to "unsuitable" bed capacity. By "replaceable" bed capacity we mean rooms and departments that are now included in existing bed capacity but that would be differently designed when their physical condition required replacement by new construction. In such authoritative hos-

units—large hospitals need more toilets or janitor closets, not larger ones. In some functional units, such as waiting rooms, staff conference rooms, and medical records rooms, the space allocation increases in proportion to the number of beds in the hospital, but in others the picture is not as clear. For example, if the director of nursing service in a 50-bed hospital needs an office of 130 square feet, it does not follow that in a 100-bed hospital the same type of office needs to be twice as large, or any larger. In "Elements of the General Hospital" the office in the 50-bed hospital is designed for one person and is furnished with one executive desk, chair, and wastebasket, two straight chairs, one bookshelf, and three filing cabinets. The office in the 100-bed hospital is also for one person and has the same area and same furniture, except that it has only two filing cabinets instead of three (7). Is there then no need to increase the size of areas such as this in proportion to the increase in normal bed capacity?

The answer is that a functional unit such as the office of the director of nursing service need not be enlarged, but the area of the whole administration department of which it is a part does need to be enlarged to accommodate the increased work of directing the nursing service. The more beds in the hospital, the more patients and nurses. The more nurses, the more time records, dossiers and registers, correspondence and conferences, each requiring a little more space. Recognition of this and similar needs is given by suggesting 2,975 square feet for the administration department of the 100-bed hospital in contrast to 1,970 square feet in the 50-bed hospital (5). When the hospital increases to the 100-bed level, the office of the director of nursing service remains constant, but provision is made for the increased records and activities to be accommodated in part in a larger business office with five employees instead of three, in the larger medical records, conference, and waiting rooms, and in two types

Table 1. Area distribution in net square feet per bed for departments of general hospitals

Total.....	587.0	627.9	532.4	507.0	501.6

NOTE: Areas do not include walls and partitions. Bed capacities are based on adult and child beds only. Space for bassinets is included in the nursery, but these bassinets are not counted as beds. The areas do not include outpatient department, quarters for personnel, nursing school or any other teaching areas, fuel storage, garage, or any other area not specified in the department column. For a detailed description of units within the departments by size of hospital, see reference 5.

SOURCE: The five columns correspond with the data summarized in reference 5 for hospitals of 25, 50, 100, 150, and 200 beds, respectively, with the following modifications: (a) a formula room of 255 square feet has been included in the 50-bed hospital dietary facilities as the omission of any formula room in a hospital of this size was apparently an error; (b) small errors in addition or rounding have been corrected.

Bed complement. The term "bed complement" refers to the number of beds set up and ready for use at any given time, regardless of the floor space allotted to the beds or the areas in which they are found. Bed-complement figures are often misleading because they do not indicate the normal safe and efficient working capacity of a hospital. Complement includes beds crowded into rooms intended for fewer patients and beds that have been set up on enclosed porches, in hallways, solariums, treatment rooms, and other areas not originally designed for occupancy by bed patients. Bed-complement figures may be misleading also when, as in resort areas, a portion of the hospital is closed during the off-season.

Normal bed capacity. The evaluation of existing facilities and the design of new areas for patients must be based on the concept of normal bed capacity. The term refers to the number of hospital beds appropriate for the patients' rooms as the result of two factors in design: (a) the provision of a minimum number of square feet per bed and (b) the intention of the designer. The second factor governs in instances where, according to minimum space standards, the area of a room seems sufficient to accommodate a larger number of beds than that for which it was designed.

For example, a hospital room designed for occupancy by only one patient is not to be considered as a two-bed room merely because it has an area as great as the minimum prescribed for a two-bed room. A one-bed room may be relatively large because it was designed as a luxury accommodation, or more frequently the room may be intended for the isolation of a noisy alcoholic or mentally ill patient or one with a communicable disease. In such rooms the location of toilet, lavatory, and storage space and the inclusion of such features as double doors may preclude the accommodation of two beds for average patients without a dangerous or inefficient degree of crowding.

Potential bed capacity. This is a term not frequently encountered. As defined by the Commission on Hospital Care, potential bed capacity designates areas of the hospital currently used for other purposes but intended for the eventual accommodation of patients as the need for hospital beds increases. For example,

student nurses might be housed for a time in a division of the hospital designed for future conversion to a nursing unit for patients.

Standard Space Allocations

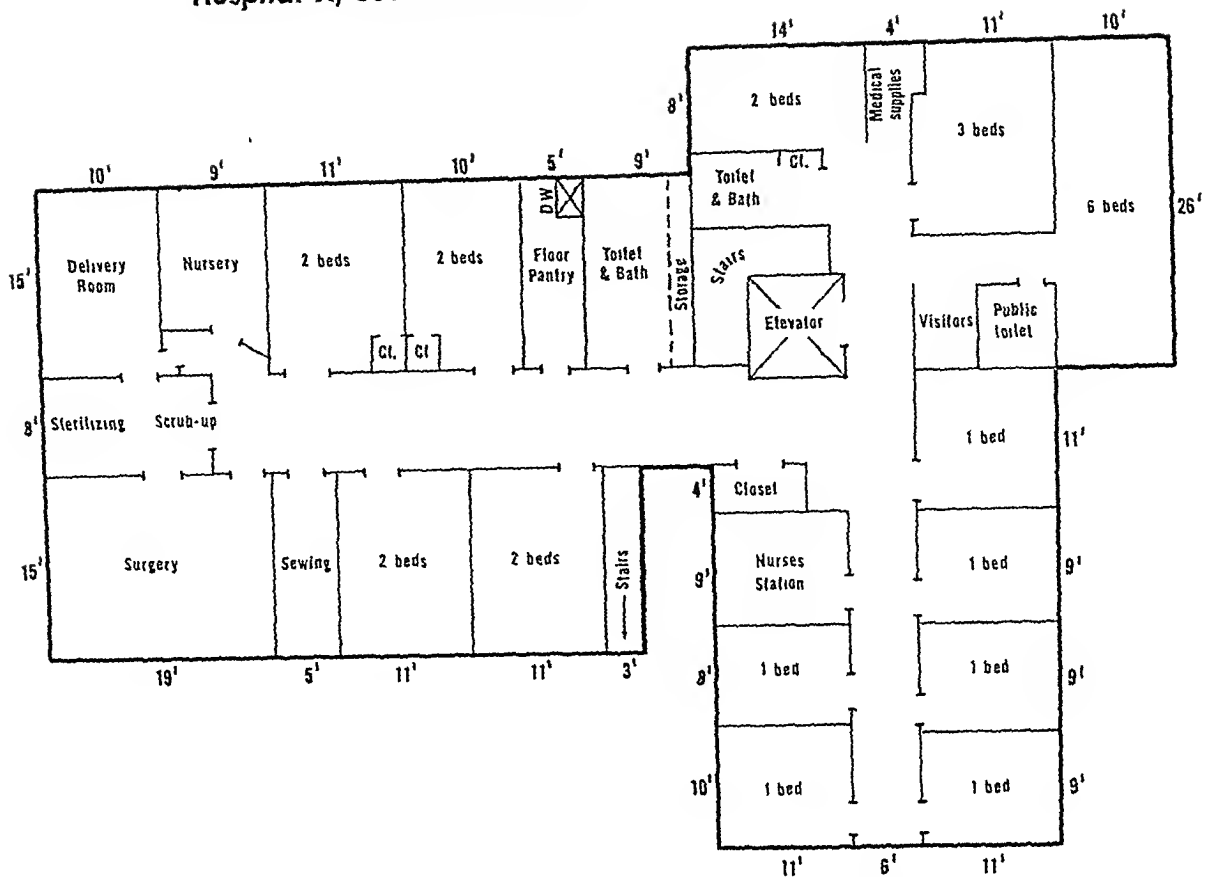

The space allocations used as standards in this study were first published by Shaffer and MacDonald in 1943 (4) for hospitals built in the emergency defense program under the Latham Act. They appeared in *Modern Hospital* in 1947 and 1948 in a series of articles entitled "The Functional Basis of Hospital Planning," prepared by the Hospital Facilities Section of the Public Health Service. The series was reprinted as a 110-page monograph, "Design and Construction of General Hospitals," subtitled "A Definitive Study of the Physical Aspects of the Hospital Plant in Relation to Its Function" (5).

The standards are minimum (6). In fact, a related series of articles published by the Public Health Service in 1946 suggested larger dimensions of various elements of the general hospital for new construction (7), and some of these elements were revised upward in 1952 (8). Many hospitals constructed under the Hill-Burton Hospital Survey and Construction Act exceed the suggested floor areas, for example those described in three articles in the *Journal of the American Institute of Architects* (9). More ample areas were recommended in a 1954 publication from another source (10), and present indications are that future revisions of the standards will call for larger areas. However, the 1947-48 standards seem to be reasonable for judging existing structures.

Standards for Hospitals of Different Sizes

Because "Design and Construction of General Hospitals" gives figures only for hospitals of 25, 50, 100, 150, and 200 beds (5), it was necessary to devise some method of assessing the measured capacity of existing hospitals of intermediate sizes. The problem was complicated by the fact that no one department has a constant number of square feet per bed throughout the range from 25 to 200 beds. In attacking this problem we were well aware that in many instances the space needs of a hospital increase by multiples of functional units rather than by an increase in the size of the individual

Hospital X, Second Floor Plan

partments with minimum standards for hospitals of similar size. The following is a comparison of two actual hospitals.

Hospital X

Hospital X occupies a two-story building, with partial basement, that was designed as a hospital. The exact date of the original building is unknown. One section was remodeled in 1936 and some changes were made in other sections in 1946 and 1951. The general layout of the hospital is indicated by the sketch of the second floor (see chart). Although the structure did not have a fire-resistive rating of 1 hour or more, a sprinkler system complying with State licensing regulations was installed and the building was considered to be suitable.

The 1958 revision of the State Plan for the Construction of Hospital and Medical Facilities listed hospital X as having 40 acceptable beds. An average daily census of 32 was reported for the previous year, which would re-

quire 49 beds for high-level and 55 beds for low-level occupancy, according to the Commission on Hospital Care (2). On the day of our survey, 45 beds were set up. There were 41 patients in the hospital, nurseries excluded.

Normal bed capacity. The area in each room was measured and its maximum capacity was calculated according to our index (p. 678). The figures in table 2 show that although hospital X had a bed complement of 45 on the day of the survey, the normal bed capacity of its rooms for patients totaled only 32. Instead of being set up with 6 one-bed rooms, 13 two-bed rooms, 2 three-bed rooms, 1 six-bed room, and 1 bed in a hall, hospital X should have had no more than 11 one-bed rooms, 9 two-bed rooms, and 1 three-bed room.

Departmental areas. The adequacy of space in other departments essential to the care of inpatients was determined by comparison with the standard space allocations for hospitals of 32 beds. Each functional unit was measured,

of rooms that first appear at the 100-bed level—social service and retiring room (7, 8).

A stepup in this element of a general hospital comes at the 200-bed level, where provision is made for two offices of 215 square feet each, one for the director and one for two assistant directors of nursing service. At this level the increased prestige of the director is acknowledged by giving her a larger office, although not too large for a supervisor of a staff of 80 to 100 nurses and auxiliary workers.

In any event, one can discern the principle that as the volume of hospital service increases a roughly proportional increase in the various departmental areas is required, although the need for more space to perform a specific function may be hidden for a time by the shifting or delegation of various components of the function to other areas.

It was primarily the hidden growth factor explained and illustrated above that influenced us to calculate the space needs of hospitals of other than the sizes in "Design and Construction of General Hospitals" by interpolation and by extrapolation beyond the upper and lower figures. The midpoints between hospitals of given sizes were used to demarcate the size classes of hospitals to which a given number of square feet per bed applied: 15-37, 38-74, 75-124, 125-174, and 175 beds and over, as shown in table 1.

Departmental Areas and Units

The 587 square feet per bed suggested for a 25-bed hospital was assigned to hospitals of the 15-37 bed class, the 627.9 square feet for a 50-bed hospital was assigned to the 38-74 bed class, the 532.4 for a 100-bed hospital to the 75-124 bed class, the 507 for a 150-bed hospital to the 125-174 bed class, and the 501.6 square feet per bed suggested for a 200-bed hospital was assigned to hospitals of 175 beds and over (5). Table 1 presents the standard net square feet per bed for each department according to hospital size. To obtain the standard area for a department in a given hospital, the square feet per bed for the size class in which the hospital falls is multiplied by the normal bed capacity.

A standard square footage per bed for some of the large units within the departments can

be derived in the same manner, but for the reasons given in the subsection, Standards for Hospitals of Different Sizes, it is not often permissible to go below the departmental level in interpolating or extrapolating.

Rooms for Patients

The maximum normal bed capacity of each room for patients is calculated from the following range of square feet per number of beds in a room:

<i>Number of beds</i>	<i>Range in square feet</i>
1-----	95-149
2-----	150-224
3-----	225-299
4-----	300-374
5-----	375-449
6-----	450-524
7-----	525-599
8-----	600-674

This index is based on the minimum of 100 square feet of open space for one-bed and 80 square feet per bed for multiple-bed rooms (private closets, lockers, toilets, and showers excluded) required for hospitals to be constructed under the Hill-Burton Act (11). We believe this choice of standard is justified because our purpose is to analyze and evaluate existing structures rather than to plan new construction.

In applying these standards to patients' rooms, deviations of 5 square feet per bed below the minimum are accepted because measurements made in the field are not highly exact and because of the difficulty of making allowances for columns, radiators, ducts, and similar design features. The majority of measurements, except for small areas such as closets and toilets, were made with a measuring wheel device. Dimensions were recorded at the hospital or rounded in the office to the nearest one-half foot. For example, a dimension measuring between 9 feet 9 inches and 10 feet 2 inches would be recorded as 10 feet, a tolerance of 5 percent. The interval between 11 feet 3 inches and 11 feet 8 inches would be represented by 11 feet 6 inches, and so on.

Application of Method

The method described in this article compares the space for beds and supporting hospital de-

private toilets and very few have closets. There are no subutility rooms, nurses' toilets, or janitors' closets anywhere in the hospital. There is only one nurses' station for two floors and basement. The floor pantries are substandard in size, and the storage areas for linen and other supplies that should be on hand in the nursing unit are not only too small but are all on the second floor, far from the patients' rooms on the first floor and in the basement.

Hospital A

This one-story and basement fire-resistive structure, built in 1956, was designed to accommodate 42 patients in 2 one-bed, 16 two-bed, and 2 four-bed rooms. The one-bed rooms each contained 135 square feet. The multiple-bed rooms each contained 80 or more square feet per bed.

Normal bed capacity. According to our method the normal bed capacity was 40. There

were five beds in one room of 395 square feet, sufficient open space to permit classification as a five-bed room, according to our index, but it was clearly designed for four beds, having no bay for a fifth bed and being identical with another room in which only four beds were set up. As shown in table 5, the space allocated to obstetrics was notably deficient and there was no physical therapy department. The nursing department was deficient in having only two

and the dimensions and the use being made of each room at the time of the survey were recorded on floor plans of the hospital (see chart). The data were processed in our office by assigning each room to the appropriate department and entering the dimensions and square feet on forms that grouped the rooms by departments and indicated whether the function was required for a hospital of this size.

The comparison of the areas in each department of hospital X with the corresponding standards for a 32-bed hospital shows a measured deficit of 9,018 square feet. The departments that were most deficient were surgery, with about one-fourth of the space it should have in a 32-bed hospital, obstetrics with 150 instead of 941 square feet, and dietary with 445 instead of 1,434 square feet. Administration had only 575 instead of 1,504 square feet (table 3).

The departmental deficiencies can be seen more clearly if considered in the detail suggested by table 4. The surgical department has insufficient space for central sterilizing and supply, and no space at all for substerilizing room, unsterile supplies, cleanup room, doctors' locker room, janitor's closet, and anesthesia storage. The obstetrics department has inadequate space in the delivery room and none for labor room, substerilizing, cleanup or utility room, and janitor's closet. There is no scrubup room for the obstetrics department alone. The surgical scrubup room serves both departments.

Although departmental deficiencies appear most clearly in administration, surgery, obstetrics, and the service departments, it is important to note that the nursing department lacks 1,560 square feet of the space needed to support the normal capacity of 32 beds. From the floor plan it can be seen that most of the rooms for patients have no private or semi-

Methylchloride Intoxication

One death and two serious illnesses occurred recently in a small Kentucky plant fabricating Styrofoam parts, used primarily for insulation of refrigerators. The Occupational Health Branch, Public Health Service, the Kentucky State Department of Health, and the company which produces the Styrofoam cooperated in an investigation.

Symptoms were those of central nervous system damage. The man who died had worked on various machines fabricating Styrofoam parts for more than 2 years. A few weeks prior to his death, he developed what appeared to be a slight cold, followed a few days later by dizziness. The two other employees who became ill also showed signs of dizziness, accompanied by a staggering gait.

Methylchloride is used as a foaming agent in the production of Styrofoam. The material contains many tiny unconnected cells filled with the gas which is released when the Styrofoam is cut or sawed. In the Kentucky incident, poor ventilation during prolonged cold spells led to the accumulation of dangerous amounts of methylchloride in the work environment. The plant agreed to remain closed until adequate ventilation equipment could be installed.

one-bed rooms. The other deficiencies, in pharmacy, surgery, dietary, and housekeeping were minor.

Potential bed capacity. As shown in table 5, a room of 190 square feet used to store furniture had been designed for patients and provided a potential capacity of two beds. Also, 11,810 square feet of undeveloped space in the basement was adequate to make up the total deficiency of 2,473 square feet in physical therapy, nursing, surgery, obstetrics, dietary, and housekeeping, if and when necessary, and in addition it provided a potential capacity of 7,879 square feet, enough to provide supporting departments for an 18-bed addition to the nursing department.

Findings for Two Hospitals

One of the two actual hospitals used to illustrate the method had 45 beds set up on the survey day, but was found to have a normal capacity of only 32 beds and a measured deficit of 9,018 square feet in the departments essential for a 32-bed hospital.

A more modern hospital with 42 beds set up on the survey day was found to have a normal capacity of 40 beds and a potential capacity of 2 additional beds. It had sufficient unassigned space to compensate for existing deficiencies in the departments, and undeveloped space sufficient to support an 18-bed addition to the nursing department if and when it should become necessary.

Surplus Space

Surplus space in a department or a hospital is not necessarily an extravagance. For small hospitals especially it has been recommended that new hospital construction provide basic facilities for future expansion of 50 percent or more. "... growth is to be expected and it should be planned for. It is good policy to install in a 50-bed hospital, for instance, service facilities large enough to care for 100 patients and to draw plans paving the way specifically for expansion to that capacity. Then when demand has reached the point where expansion is justified, patients' rooms can be added at minimum expense and with minimum dislocation of existing services" (12).

Conclusions

As a result of our studies, we strongly recommend that existing hospital facilities be re-surveyed on the basis of the criteria outlined below, to determine whether they have sufficient space, properly distributed, to meet the functional demands of modern hospital care and to guarantee a reasonable measure of safety for the patient.

1. Each division, wing, or building that is unsafe or unsuitable for its purpose because of fire hazards, physical deterioration, and dangerous structural features or materials should be classified as "unsuitable." Thenceforth, only areas that are suitable should figure in the calculation of normal bed capacity and space utilization in the basic departments.

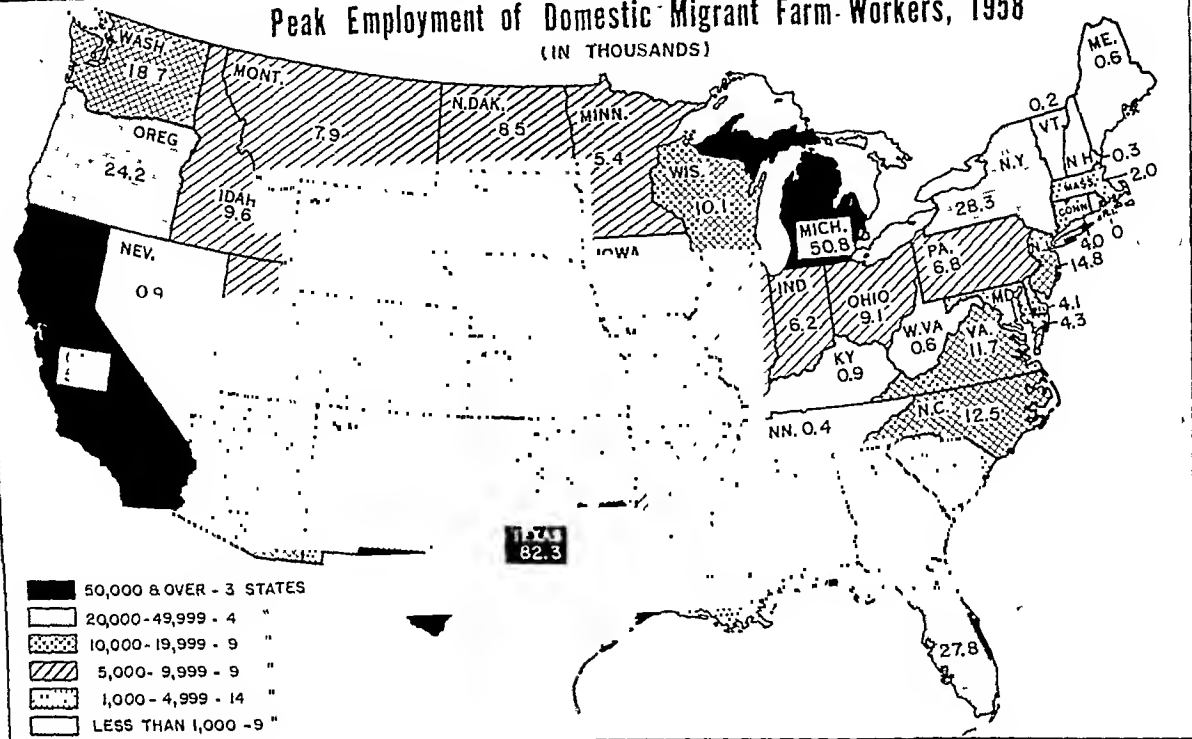

2. The rooms for patients in the nursing department should be measured and classified as described in this article to determine the "normal bed capacity." This figure should supplant the current usage of "bed capacity" that is usually based rather loosely on sources no more objective or authoritative than an unsupported statement from the hospital, or inspection without measurement.

3. The other rooms in the nursing department and the areas of all other basic hospital departments should be measured, and the standard areas required by the normal bed capacity should be calculated as described in this article.

4. The deficiency in each department should be calculated by subtracting the actual from the minimum standard area. Because this method deals with minimum figures, only deficits are counted. Surpluses should not be counted, with the single exception of potential bed capacity as defined early in this article.

This index of normal bed capacity and departmental space needs provides a quantitative measure of the adequacy of the individual hospital. It also constitutes an important step toward a complete and objective definition of hospital obsolescence, which is essential to determining the extent to which the hospital needs of a region (or a State or a nation) are met by existing and proposed hospital buildings. The hospital with deficits in essential departments can be regarded as obsolescent in that it cannot meet functional demands for modern hospital care.

Peak Employment of Domestic Migrant Farm Workers, 1958 (IN THOUSANDS)

Federal act. States are encouraged to be liberal by the Federal agencies involved.

Certain types of illnesses which are of public concern, for example, tuberculosis and venereal diseases, are also treated with greater liberality by some States, regardless of the residence of the patient. Migrant labor is considered a high-risk group with respect to incidence of communicable disease. Maternity, chronic diseases in young children, and accidents also bring some relaxing in State residence requirements.

Local communities in some areas have attempted to meet immediate problems of health services for migrants by setting up clinics, as in Fresno, Calif. Church groups have sometimes identified health needs in migrant camps and acted as referral agencies. Junior leagues have set up sick baby clinics and provided free medical and nursing aid. Local public health departments have added extra nurses to their staff during the peak of the crop season. They have set and maintained levels of sanitation and environmental health in migrant labor camps.

The major part of funds to finance health services for migrant agricultural workers has come from private sources, and much has come involuntarily. Hospital and medical bills are simply left unpaid at the end of the crop season. These are eventually charged to charity care, unless the "home" county or the individual growers or the growers' associations or processing companies can be persuaded to meet part or all of the bill.

With few exceptions, there is little evidence that efforts to provide migrants with health services even temporarily consider at the same time possible ways to reduce needs, and thereby costs, through improvement of housing and sanitation, accident prevention, and other measures. Although many adaptations have been made to try to fit programs to migrants, at the present time none that the committee identified provides for more than the temporary period of a migrant's residence and employment in a single location except programs for offshore and foreign workers and isolated programs for domestic workers under somewhat similar working conditions. Moreover, the extent and kind of services afforded mi-

Financing Health Services For Migrant Farmworkers And Their Families

THE PRESIDENT'S Committee on Migratory Labor, composed of the heads of five member agencies—the Departments of Agriculture, Health, Education, and Welfare, Interior, Labor, and the Housing and Home Finance Agency—has prepared a working paper on Financing Migrant Health Services.

The paper is basically a resource document and covers various methods currently in use or proposed to finance health services for foreign and offshore workers, and for domestic farmworkers in the continental United States. Health services as defined by the committee range from preventive services (including sanitation) through short-term and long-term medical care.

The committee found that the current programs and proposals for financing migrant health services run the gamut of those found in existence for the general population. Responsibility for planning, providing, and financing these services has been taken in the community by various groups such as individual employers and employer associations, private medical personnel and medical organizations, public health agencies, civic and church groups, private and public welfare agencies, private insurance carriers, and migrant labor crewleaders and the migrants themselves.

The committee considered existing voluntary health insurance programs, provision for medical care and indemnity under workmen's compensation laws, medical and related care under public programs such as general assistance (with special consideration to residence requirements), and a variety of grower- and community-sponsored programs and proposals.

The committee also compiled a number of recommendations made by recent conferences on agricultural migrants and by national voluntary organizations as a guide to interested private and governmental agencies in their consideration of methods of financing the health care of agricultural migrants. The inclusion

of specific programs or proposals does not imply endorsement, nor the omission of others unacceptability.

Of particular interest is the summary of health insurance coverage in existence for Mexican nationals, British West Indians, and Puerto Rican contract workers, by type of carrier, coverage, premiums, and benefits. The health insurance arrangements are made under the auspices of governmental agencies, but are provided by private insurance companies. They cover the foreign and offshore worker from the time he enters the United States to work (and in some instances even before arrival) to the time he leaves. Domestic migrant agricultural workers as a labor force group are not so covered, except in scattered and minor instances.

The digest of farmworker coverage under workmen's compensation laws, by States, is also an important and useful source table. There are no States in which the law—compulsory or elective—applies to migrant farm labor as such. If migratory farmworkers are covered, it is by virtue of the fact that agricultural workers per se are covered. Under some State laws, even if workers are covered as a class, they may not be covered as individuals because of numerical exemptions per employer.

An analysis of medical and related care under public programs highlighted the residence requirement for eligibility under most State and local general assistance laws and regulations. Residence requirements varied from 6 months to 5 years out of the last 9 years, with 1 year the average. Since so many migrant workers are "stateless," and hence ineligible for voting and other rights and responsibilities of citizenship, they are not the beneficiaries of reciprocal arrangements among States whereby residents of one State may be cared for while temporarily residing in another.

Some States which are hosts to a large number of migratory farmworkers have made efforts to provide some modicum of medical and hospital care, for example, New York, Florida, Pennsylvania, and Maryland.

Under the State programs, conducted with Federal aid, involving crippled children and vocational rehabilitation for adults, there is no reference to requirement for residence in the

Insured Psychiatric Care

EDITH S. ALT

PROVISION of psychiatric care, particularly for ambulatory persons in the low-income and middle-income groups, is high on the list of unsolved health service needs facing this Nation. Courageous experiments with insurance for mental illness, however, have suggested that it may be possible to widen distribution of psychiatric services. Notably, the Central Institute of Psychogenic Illness of the Health Insurance Fund of West Berlin offers valuable experience in this unfamiliar field.

In a national atmosphere where the potentialities of science are dramatized by radio, television, movies, and newspapers, a popular demand for efficacious psychiatric care is urgent. But there are a myraid of problems that need to be resolved before this demand can be satisfied.

The consumer, for example, often finds it difficult to determine for himself or his family what constitutes an appropriate psychiatric referral. And the consumer is not alone in this dilemma. The psychiatrist's colleagues in other specialties of medicine, social work, law, education, housing, and industry often refer to him the recalcitrant, uncooperative person whom all have given up as too difficult to deal with in the normal course of events.

In other words, the range of problems considered appropriate for psychiatric referral can be as broad as life itself (1). Moreover, the pressures generated by individuals who feel the need of care, by professional colleagues, or by community services acting on their own behalf

are such that an extraordinary amount of psychiatric time is diverted and not necessarily well used.

The first step then is to define what is meant by psychiatric need. Within the context of these remarks, I shall limit the use of the phrase "psychiatric need" to designate psychiatric illness. This confines the definition to those manifestations of illness that seriously interfere with normal and usual functioning of adults and children in the activities of daily living. It excludes many kinds of expressions of deviant behavior as well as the wide variety of measures designed to make people happier.

If we accept these limitations, the next step is to relate the nature of the psychiatric problem to the kind of treatment needed. The present failure to clarify this relationship has resulted in an enormous waste of psychiatric time, and has added to the frustration and confusion of the consumer who does not know where to turn or what kind of psychiatric service he should seek. The waste is also a consequence of our present lack of organized psychiatric services on a community basis. A more clearly designed community plan will have to be fashioned to conserve resources of treatment as well as to expedite referrals. Insurance protection will not miraculously wipe out this grave problem. But any systematic screening method that will help consumers clarify and assess their need, and bring them more directly toward the kind of psychiatric treatment required, is bound to have a profound effect upon the practice of psychiatry and contribute to its productive use.

New York's Plan

In this connection, it seems pertinent to refer to experience in the Health Insurance Plan of Greater New York. Since its establishment 12

Mrs. Alt is the director of the division of community resources for the Health Insurance Plan of Greater New York. This paper, in somewhat different form, was originally presented at the conference of the American Psychiatric Association in Chicago, May 1-4, 1957.

grants, and the circumstances under which they are offered and financed, differ widely from one locality to another. A typical domestic farm migrant is unlikely to find the same conditions prevailing in any two places where he lives and works during the year, especially if his work itinerary covers two or more States.

Migrants share with other low-income farm people problems in financing health care through insurance or other means; they share with most other farmworkers lack of workmen's compensation coverage; and they share with other mobile groups problems of obtaining care in areas where residence restrictions are

applied as a condition for eligibility. Proposals directed toward these broader groups hold promise for the migrant population.

Among the continuing needs in order to facilitate the provision and financing of health services to domestic migrants are (a) the stabilization of their employment situation; (b) the incorporation to the fullest extent possible in the domestic worker program of the standards now found in the foreign and offshore program; (c) the availability of some common denominator of health service and educational and informational effort from one community to another.

A Charge on Our National Conscience

It is intolerable and indecent for a society to produce by overworking and underpaying human beings. Even if the product may cost more, we, in this country, usually accept the difference in cost because it is the man that counts—not the thing.

It is my conviction that the migrant farmworker will never take his place as a fully useful citizen, and never be able to successfully resist exploitation, until, first, Federal legislation guarantees him a decent minimum wage upon which he can build a decent and independent life; second, unless he has fairly continuous employment; third, until he receives the equal protection of all Federal and State laws, such as enforced housing codes, enforced safety codes, accessible health services, and protection of his person in the form of compensation for injury and unemployment.

Progress in the health of migrants depends upon the removal or adaptation of residence requirements in the States.

The Federal Government can act in certain directions—research and inform—but it cannot teach or develop and enforce housing codes or State highway safety codes or care for the medical needs of all our citizens. The States must do that, and the communities within the States . . . only they can take the big step, removing the residence requirements that keep the school doors locked against migrant children.

The migrant and his family are lonely wanderers on the face of our land. They are living testimonials to the neglect that is possible in a wealthy and aggressive economy that prides itself on the protection of the individual. They have no lobby—no power at the polls. Their lot often seems hopeless. But if we really want to help, we can—continuously, undramatically in action, not mere words. We must, for the migrant is a charge upon the conscience of us all.—HONORABLE JAMES P. MITCHELL, *Secretary of Labor*. (Excerpts from statement at hearings of the National Advisory Committee on Farm Labor, February 5–6, 1959.)

needs, setting psychiatric treatment apart as not an essential ingredient of medical care. From a practical point of view, lack of such service cannot help but increase the irritation and frustration of physicians treating subscribers who are not getting the psychiatric care they need. As in private practice, these patients often become high utilizers of medical services.

Broad Financial Aspects

We should now look at the broader population to get a fuller understanding of the financial aspects of the problem. Let us consider the fact that 1 family out of 6 in the Nation has an income of \$7,000 (2). If we are considering those who can really afford to buy psychiatric care on a private basis, we should have to restrict the population to those having a family income of \$10,000 per year. This represents 1 family in 14.

The inability of most of the population to pay for psychiatric care on a private basis becomes even clearer when we study the net income and cost figures. The crucial fact is that only 10 percent of the population at the present time is in a financial position to buy private psychiatric care. In other words, some 90 percent of the population must either look to philanthropic or governmental sources for treatment or delay treatment, go without treatment, or build up excessive debts.

A report prepared by the Community Council of Greater New York (3) analyzes the amount of money available, beyond basic living costs for employed persons and heads of families, to purchase psychiatric care. This study reveals that a family of four with an annual income between \$7,000 and \$8,000 and living modestly in a metropolitan community would have only \$7 or \$8 a week for psychiatric treatment fees over a period of 50 weeks during the year. A family of four with an income of \$10,000 might conceivably have not much more than \$20 a week for psychiatric fees.

We can assume that the inability of many medical care programs to include psychiatric service is due to the high cost of this service and its scarcity. However, with the trend in this field moving from hospital care to community care, we see a change having important

bearing on our discussion. With the consumer's increased knowledge about psychotherapy, optimistic reports of shorter treatment periods, and more emphasis on early casefinding in hospitals, group practice, and health centers, we can expect that more people with psychiatric illness will come for treatment and at an earlier time in the illness. This is particularly true for the insured consumer. A nationwide family survey, conducted by the Health Information Foundation, revealed that insured families, regardless of income, are more likely to use services available to them than uninsured families in the same groups (4).

There seems to be little doubt that the demand by consumers for psychiatric care is rolling up around us. We see, for example, an increasing number of organizations sponsored by citizens springing up in all parts of the country, and each is trying to find solutions to various aspects of this problem.

The complexities involved in providing the consumer with protection through insurance are apparent, especially since we believe the standards for this care should be similar to the standards for other medical care. In other words, a psychiatric program should remove the economic deterrent to those seeking help. It should provide treatment adequate in amount, kind, and quality as early in the onset of the illness as possible. Appropriate participation by the related professions of psychology, social work, and therapeutic education should be an integral part of the plan. Its design needs to take into account the fears, anxieties, and resistance of patients who are seeking, accepting, and utilizing this kind of care.

West Berlin's Plan

The Health Insurance Fund of West Berlin, with its Central Institute for Psychogenic Illness, has been able to meet a wide variety of psychiatric needs, including psychotherapy. From first-hand information gained during a visit to Germany in the summer of 1956 and from the 1953 and 1954 annual reports of the program, I can give the following description.

One of the reports states that the basic premise underlying the program is that a great deal of illness "is not primarily organic but is emotional or mental in nature. The Health Insur-

years ago, the plan has worked with a wide range of psychiatric and emotional disorders requiring treatment, and has had to struggle to match needs with scarce treatment services available at fees possible for most subscribers.

The Health Insurance Plan provides psychiatric consultative and diagnostic services. It is a prepayment insurance organization, community sponsored, with medical care provided by 32 separate medical groups. Each medical group has at least one psychiatrist. Referral to community resources may be had through social services within the plan.

Psychiatric consultation is available on referral by the family physician or by other specialists so that the patient can receive consultation without delay. This means that the subscriber has the benefit, without financial barrier, of early detection and diagnosis of a psychiatric condition. An added advantage is that the physicians in the medical groups have known their patients over a period of years and, therefore, often have pertinent information on their general health and family situations.

These are distinct gains. But since the plan does not, as yet, include psychiatric treatment as a benefit, HIP is chronically pressed to find psychiatric treatment services for those diagnosed as needing such care.

It is my impression that the experiences of HIP in seeking psychiatric care for subscribers confirms the general community experience. The HIP population includes a representative cross section of a metropolitan community: school teachers, policemen, sanitation workers, governmental employees of all levels, writers, clerks, movie projectionists, machinists, and business executives among others. On an income basis, we find that approximately 90 percent of the subscribers report their earnings as less than \$5,000 annually if single, and \$7,500 annually if heads of families. This leaves 10 percent reporting their earnings as beyond these rates.

Recognizing that the bulk of the HIP population falls into the low- and middle-income groups (actually not too different from our national distribution), it follows that the psychiatric fees they can afford to pay are limited, unless they go into debt or change their living pattern. Some of these consumers may

have the double handicap of limited funds and a discouraging diagnosis.

In many communities it is clear that among the adults and children most urgently needing care today are the extremely ill who are not yet in State hospitals or are not eligible. These are the individuals for whom ambulatory or day care is most difficult to obtain. Many clinics, agencies, and private psychiatrists find them difficult to manage and too unrewarding to be accepted for treatment.

Besides patients with extreme or chronic mental illness there are others for whom care is particularly difficult to obtain: individuals who require immediate treatment in order to meet crises; those who with intensive treatment could avoid hospitalization; and those whose conditions can be diagnosed adequately only through a comprehensive study employing interdisciplinary collaboration.

There are others whose psychiatric needs are interwoven with serious medical difficulties. Within this category are those with amputations, allergies, ulcers, and heart conditions who need integrated treatment. Among these, and others, we find persons whose ability to function in work, education, and family life is so seriously impaired that they require psychiatric treatment to attain a self-maintaining level of living.

Disadvantages in not providing psychiatric treatment as part of a comprehensive medical care plan are recognized by most organizations providing such care. In HIP, the psychiatrists themselves have urged that as soon as it is feasible psychiatric treatment should become a part of the plan.

In addition to the clinical need to provide treatment service, especially for those needing short-term ambulatory care, there are additional values from a mental health point of view that deserve mention.

Excluding psychiatric treatment from any plan may well reinforce in a patient the feeling of being a special problem, of being different, or of having a stigma. At the same time, it is not unlikely that physicians in other specialties would be affected in their attitudes toward psychiatric treatment. Exclusion strengthens any sense of difference the physician might harbor between psychiatric need and other medical

It is difficult to compare costs for the United States and Germany for the psychotherapeutic services, since the compensation of physicians differs considerably between the two countries. At their own rate of payment, it costs the institute an average of DM 750 per patient served per year. At the present rate of exchange, this would be about \$178.50.

The full-time physicians receive monthly salaries ranging from DM 700 for the young psychiatrists to DM 1,400 (before 20 percent taxes). The payment is DM 5.00 per hour for medical therapists and DM 4.00 per hour for nonmedical therapists. Each psychiatrist sees about 7 patients twice a week and participates in screening about 16 or 17 applicants a week.

The provision of psychotherapy, though it had been included in the health insurance program for 10 years, was still a controversial issue. However, four other cities in Germany also give psychotherapy services to subscribers of their insurance plans: Munich (paid by social insurance and the university), Göttingen, Heidelberg, and Hamburg.

It is the belief of those at the institute that a great deal of knowledge has been accumulated with regard to the appropriate integration of psychotherapy within the framework of medical care. As a result, they look forward to replacing full analysis for the treatment of neurosis with psychotherapy, in certain circumstances.

For those interested in further substantiation of the results of the psychotherapy program, the Central Institute for Psychogenic Illness has published studies assessing their achievements.

Conclusion

It is my belief that the consumer's demand for psychiatric treatment will continue to increase. The problem of mental illness, now that it is in the open and acknowledged, goes to the heart of our social health. Those working in the field can, hopefully, influence the forms the solutions will take.

We cannot underestimate the complexities and difficulties that must be faced in order to achieve sound planning. At the same time, I should urge that an understanding of these problems be shared with consumers so that their efforts can supplement those of all professional and planning groups striving to meet these needs.

Summary

The experience of the Health Insurance Plan of Greater New York, which provides psychiatric consultation but not treatment, offers abundant evidence of the need for more readily available and financially feasible psychiatric services for low- and middle-income groups. From the fact that only 10 percent of the people in the United States can afford private psychiatric care, it is clear that the lower income groups face a serious problem in obtaining psychiatric help, particularly psychotherapy of long duration.

An existing insurance plan, the West Berlin Health Insurance Fund, with its Central Institute for Psychogenic Illness, has been able to provide its members full study, psychiatric treatment, and psychotherapy. Each member accepted for treatment (more than one-third of the applicants) receives 150 to 200 treatment hours over a period of 1 to 1½ years.

ance Administration therefore organized the Institute for Psychogenic Illness . . . so that insured persons could receive psychotherapeutic treatment."

The health insurance program, which covers some 750,000 people, operates through a series of polyclinics, or health centers, located in various districts of the city. Psychiatrists in these polyclinics may themselves treat patients with psychiatric problems, using any of several psychiatric methods, including shock therapy or sleep therapy. For psychotherapy, however, they refer patients to the Central Institute for Psychogenic Illness.

The psychotherapeutic services are given only to ambulatory patients who are able to remain in the community. In addition to patients referred by the polyclinics, the institute cooperates with mental hospitals in the region by accepting for followup some patients after they are discharged.

The Health Insurance Fund provides for 150 to 200 treatment-hours for each patient, but the institute tries to get results in 100 hours. Both individual and group therapy are provided. Patients receiving individual treatment are seen 2 or 3 times a week over a period of a year or a year and a half.

Patients referred to the institute are given at reception a preliminary examination lasting 1 to 2 hours. Later they receive a complete physical examination including extensive neurological examination. About 2 weeks after that, the patient returns for the institute's decision as to whether he is accepted. Two psychiatrists and an internist review the findings, decide whether the patient is treatable, and outline the general plan for treatment if the patient is accepted. A diagnosis is established.

The institute sees from 120 to 150 new adult patients and from 50 to 60 new children a month. Of these, according to the institute's criteria, one-third are not treatable, one-third have a good prognosis, and the final one-third are in a borderline category. Those considered unsuitable for treatment are referred back to the polyclinic or to some other service for supportive psychiatric or social care. The one-third with a good prognosis are generally accepted, and the one-third that are considered borderline are studied more carefully to deter-

mine whether or not they can be helped. The institute staff apparently tries to accept the borderline group if there is any possibility of response to treatment.

The waiting period between acceptance and beginning of treatment is usually about 3 months.

The comprehensive character of its diagnostic and screening service seems an important factor in the successful operation of the program. Many believe the institute's ability to maintain stable and effective service lies in the team studies that precede the decisions for accepting a patient. Another significant factor in the institute's program is the seeming effectiveness of its time-limited psychotherapy.

In general, the institute accepts most neuroses, especially compulsive, obsessive, and agoraphobic. They do not accept schizophrenic patients.

Reports on psychotherapy are submitted to the director of the institute after the first 50 hours of treatment and when treatment is completed. If a patient has not improved sufficiently at the end of 150 hours of psychotherapy to discontinue treatment, the psychotherapist must justify an extension.

There are no psychologists with the clinic, and no psychological testing is done. Part-time group psychologists work in group therapy. There are no social workers at the institute, but the staff may call on social work service from outside agencies.

Persons treated by the institute through 1953 numbered 5,114. Investigation of 1,389 dismissed cases showed the following results: cured, 538 (39 percent); improved, 401 (28 percent); unchanged, 275 (20 percent); results not yet determined, 175 (13 percent).

In order to determine to what extent a permanent result had been achieved, special studies were made of 300 former patients whose treatment had been terminated successfully 3 or at least 2 years previously. Of these, 83.7 percent had retained the benefit of their treatment; 13.6 percent had relapsed, and the status of 2.7 percent could not be evaluated. These results were confirmed by neurologists and internists of the Central Association of Specialists, which is not connected with the Institute for Psychogenic Illness.

The inventions of clever men threaten the survival of the species. As a defense against the hazards of modern technology, health agencies have developed specific programs to control hazards in the industrial environment.

Is Man Becoming Obsolete?

DAVID E. PRICE, M.D.

IN A RECENT television program, James Thurber, in his casual way, noted that we are now living on the brink of "was." This rather neatly sums up the growing public concern that, even if we escape destruction by war, something else, probably subtle, insidious, and gradual, may eventually cause us to become a "has been" species.

The rationale for such a view is not entirely unreasonable. The technological world man has created bombards us with countless products which combine within our bodies as well as in our environment to cause reactions that we as yet know almost nothing about.

Radiation is now perhaps the major current cause of concern. How much radiation will the infants of 1959 absorb in the course of their lives from food, water, air, medical and dental treatments, and occupational exposures? What effect will it have upon them and their descendants? At this stage, we just do not know, and unfortunately the mass investment in worry is probably greater than the investment in efforts to find out.

But radiation is only one aspect of man's changing environment. With the growth of chemical industry, organic materials of un-

known toxicity are being introduced at an ever-accelerating pace. As Dr. William Shepard has observed: "Chemists can produce and put into use a dozen new products while we painstakingly lay out a 3-year research project to test the toxic qualities of one." If we live in the city, we wonder whether fumes from industry, some of them odorless and invisible, are poisoning our air. If we live in the country, we worry about the effects of the herbicides and pesticides which are applied to the land and then leach into the streams.

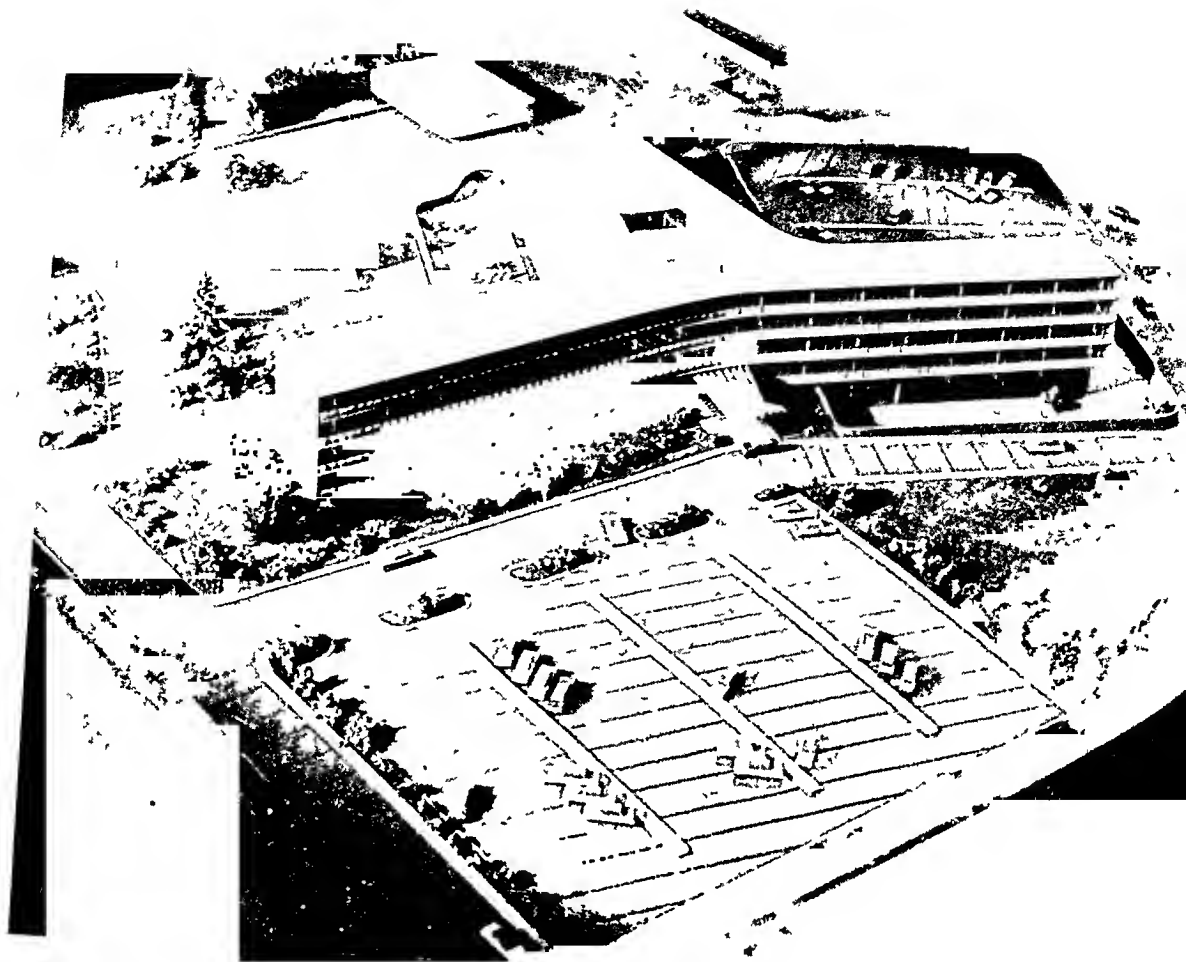

Water shortage increases the potential danger of the modern industrial environment. It is estimated that in only 20 more years our daily use of water will almost exactly equal our daily supply. And we recall that it was lack of water which caused the dissolution of the great civilizations of the Middle East.

In a way, we are modern Midases. Everything we touch and change adds to our wealth, yet in the process loses something of its intrinsic value.

Small wonder that we all live under the shadow of a haunting fear that something may corrupt the environment to the point where man joins the dinosaurs as an obsolete form of life. And what makes these thoughts all the more disturbing is the knowledge that our fate could perhaps be sealed 20 or more years before the development of symptoms.

Yet despite these ominous developments, there is an almost renaissance buoyancy in

Dr. Price, Assistant Surgeon General, Public Health Service, is chief of the Bureau of State Services. This paper is based on a text given at the 21st annual meeting, American Conference of Governmental Industrial Hygienists, in Chicago, April 27, 1959.

NEW INDIAN HOSPITAL

The hub of health and medical services for 81,700 Indians will be the new 200-bed Public Health Service Hospital in Gallup, N. Mex. Construction of the \$2,966,300 building, a modern four-story concrete and aluminum structure, will be completed in November 1960.

As the prime referral facility for 7 peripheral hospitals and 24 health centers and field stations in an area about the size of West Virginia, the hospital will serve Indians living on or near the Navajo Reservation in Arizona, New Mexico, and Utah.

Referral care will encompass not only the specialty surgical and medical services (diagnostic workup, cardiovascular diseases and gastroenterology, orthopedics, urology, gynecology, ophthalmology, and otolaryngology)

but also such specialties as neuropsychiatric and rehabilitation services which have not been available to any great extent for this Indian population.

The comprehensive outpatient department will provide complete and integrated medical care and preventive health services. The center's medical staff and consultants under contract will give specialty consultation to field personnel. The center will also serve as the training facility for the region for both hospital and field health personnel. It is anticipated that comprehensive internship and residency training will be developed in several specialties.

pollution loads tend to have higher than average death rates for certain diseases. This is a crude approach, however, and it will take a long time to study other factors which may be contributing to these findings and to determine the true significance of these observations.

The current community study in Nashville, Tenn., which involves both epidemiological observations and intensive sampling and analyses of air pollutants, is another research effort by the Public Health Service which seems promising.

Efforts to relate community air pollution to health may eventually have an effect on standards for the quality of air in the work environment. By the same token, studies of low-level exposures in the work environment may accelerate discovery of valuable clues to the hazards of community air pollution.

Probably the most publicized project in the Service's air pollution research is the study of automobile exhaust gases which is now being initiated at the Robert A. Taft Sanitary Engineering Center in Cincinnati. For this study, we are reproducing solar irradiation effects on diluted automobile exhaust gases and will expose both plants and animals to this environment. This is one of the most comprehensive studies of the automobile exhaust problem that has ever been attempted. Since many of the substances contained in automobile exhaust gases may also be emitted during metal cleaning operations, drycleaning, printing, and the manufacture of plastic, rubber, and other products, the yield in knowledge may be invaluable in controlling industrial health hazards.

Of more immediate significance is the training program. Since 1955, when the air pollution training program started, from 7 to 10 specialized courses, each lasting 1 or 2 weeks, have been given annually by the Public Health Service. More than 2,000 persons, chiefly engineers and chemists, have taken these courses. Most of them have been from public agencies, but a number have also come from private industry; in fact, last year one-third were from industry. The courses were originally given only at the Sanitary Engineering Center in Cincinnati, but for the past 2 years they have also been given in various other parts of the country.

There has been a growth in the number of colleges and universities establishing or strengthening air pollution courses. The Public Health Service has awarded 21 traineeships to students taking full-time graduate-level air pollution training and has awarded grants to 10 universities for graduate-level air pollution curriculums. This financial support for training, although relatively small, has given impetus to the whole training movement and, at present, 14 universities offer graduate courses for advanced degrees in subjects related to air pollution.

Through the Public Health Service alone, there are now three immediate sources of help.

First, a staff of specialists, physicians, engineers, chemists, and others who comprise our total air pollution program are available as consultants on new or unusual problems. We recognize that it is uneconomical for States and communities to employ regularly persons whose highly specialized skills would rarely be needed, but there is enough demand for such specialists to warrant the development of a central staff available wherever and whenever the need arises. Consequently, for the past several years, we have been recruiting such a group of specialists. They work with our regional consultants in meeting special needs.

Second, the trainees who attend Public Health Service courses and seminars form a reservoir of personnel available to State and local agencies.

Third, existing staffs from these agencies can increase their competency in the air pollution field by attending Public Health Service courses and seminars.

The National Conference on Air Pollution which met last November focused nationwide attention on the air pollution problem and I believe has stimulated industries and various other nongovernmental agencies to step up their activities in research, training, and control. Within government, the conference gave impetus to efforts to extend the Federal Research and Technical Assistance Act beyond its expiration date of 1960 and thus assure continued Federal assistance in grants to States, research, training, demonstrations, consultation, and other technical aid.

our outlook as we probe outward far into space and inward to the microcosm of the living cell. Stronger than fear is the conviction that what may at times appear to be the shadow of extinction is in reality the darkness preceding the dawn of the greatest era of progress man has ever known.

New Emphasis on Industrial Hygiene

Whether or not this proves to be true, industrial hygienists are in a peculiarly key position to predict, and in some measure to control, the nature of our future environment. Increasingly, the work environment will represent the world in miniature so that every advance in occupational health programs may contribute to advances in community health. Consequently, the problems of specific jobs have a wider significance than ever before. The day has passed when the industrial hygienist can discharge his duty by reducing the worker's exposure to concentrated toxic products. The industrial hygienist must now also be concerned about the gradual deterioration in health that may result from prolonged small-dose exposure to toxic materials. And since this is precisely the concern of those responsible for controlling the general community environment, it is not surprising to find that many States and communities are calling upon their occupational health personnel to assume major responsibility for newly developing programs in community air pollution and radiological health.

At the same time, occupational health programs cannot be neglected, as these facts clearly show:

- The 484 professional personnel staffing the 76 occupational health agencies in 40 States can cover only 10 percent of the Nation's work force.
- More than half of the industrial plants in the United States do not have even the most rudimentary type of occupational health program.
- Only about one-third of the Nation's workers are employed in large plants which may be able to afford the full range of preventive health services which is recognized to be desirable for all workers.
- Longstanding occupational health prob-

lems, such as silicosis, which we know how to control, continue to affect thousands of workers.

With so much unfinished business in established programs, one may well wonder how to meet new demands without spreading efforts too thin.

This is a question which concerns us in the Public Health Service and this is why our occupational and environmental health programs are developing and expanding those services which will be most helpful to States in meeting added responsibilities.

Air Pollution

The air pollution programs of the Public Health Service officially date from 1955 when the Federal Research and Technical Assistance Act authorized the Service to help alleviate the problem of community air pollution by providing grants-in-aid and technical assistance to States and by conducting and supporting research and training programs in the air pollution field. Actually, our work on air pollution began with work on occupational health. Industrial hygienists have always recognized that pollution of the air in the working environment is a hazard.

Removing noxious contaminants from the plant to the outside air has been a popular solution to the industrial aspect of this problem, but we are increasingly aware that it is not a satisfactory solution either for the plant or for the community. Our dissatisfaction stems from a growing realization that diluted amounts of toxic materials breathed over a long period of time may have harmful effects as surely as more concentrated amounts breathed over a shorter time period.

We do not, however, have conclusive evidence that this is true. One of the greatest needs in the air pollution field is epidemiological studies that will help us determine the effects of low-level exposures. Inplant studies as well as communitywide epidemiological studies could be most helpful. Through the air pollution research grants program, the Service hopes to encourage more epidemiological studies. Within the Service, we are comparing mortality and morbidity data with various indexes of air pollution and are finding that cities with heavy

pollution loads tend to have higher than average death rates for certain diseases. This is a crude approach, however, and it will take a long time to study other factors which may be contributing to these findings and to determine the true significance of these observations.

The current community study in Nashville, Tenn., which involves both epidemiological observations and intensive sampling and analyses of air pollutants, is another research effort by the Public Health Service which seems promising.

Efforts to relate community air pollution to health may eventually have an effect on standards for the quality of air in the work environment. By the same token, studies of low-level exposures in the work environment may accelerate discovery of valuable clues to the hazards of community air pollution.

Probably the most publicized project in the Service's air pollution research is the study of automobile exhaust gases which is now being initiated at the Robert A. Taft Sanitary Engineering Center in Cincinnati. For this study, we are reproducing solar irradiation effects on diluted automobile exhaust gases and will expose both plants and animals to this environment. This is one of the most comprehensive studies of the automobile exhaust problem that has ever been attempted. Since many of the substances contained in automobile exhaust gases may also be emitted during metal cleaning operations, drycleaning, printing, and the manufacture of plastic, rubber, and other products, the yield in knowledge may be invaluable in controlling industrial health hazards.

Of more immediate significance is the training program. Since 1955, when the air pollution training program started, from 7 to 10 specialized courses, each lasting 1 or 2 weeks, have been given annually by the Public Health Service. More than 2,000 persons, chiefly engineers and chemists, have taken these courses. Most of them have been from public agencies, but a number have also come from private industry; in fact, last year one-third were from industry. The courses were originally given only at the Sanitary Engineering Center in Cincinnati, but for the past 2 years they have also been given in various other parts of the country.

There has been a growth in the number of colleges and universities establishing or strengthening air pollution courses. The Public Health Service has awarded 21 traineeships to students taking full-time graduate-level air pollution training and has awarded grants to 10 universities for graduate-level air pollution curriculums. This financial support for training, although relatively small, has given impetus to the whole training movement and, at present, 14 universities offer graduate courses for advanced degrees in subjects related to air pollution.

Through the Public Health Service alone, there are now three immediate sources of help.

First, a staff of specialists, physicians, engineers, chemists, and others who comprise our total air pollution program are available as consultants on new or unusual problems. We recognize that it is uneconomical for States and communities to employ regularly persons whose highly specialized skills would rarely be needed, but there is enough demand for such specialists to warrant the development of a central staff available wherever and whenever the need arises. Consequently, for the past several years, we have been recruiting such a group of specialists. They work with our regional consultants in meeting special needs.

Second, the trainees who attend Public Health Service courses and seminars form a reservoir of personnel available to State and local agencies.

Third, existing staffs from these agencies can increase their competency in the air pollution field by attending Public Health Service courses and seminars.

The National Conference on Air Pollution which met last November focused nationwide attention on the air pollution problem and I believe has stimulated industries and various other nongovernmental agencies to step up their activities in research, training, and control. Within government, the conference gave impetus to efforts to extend the Federal Research and Technical Assistance Act beyond its expiration date of 1960 and thus assure continued Federal assistance in grants to States, research, training, demonstrations, consultation, and other technical aid.

The proceedings of the conference constitute an up-to-date reference book since it reports in full the papers given by some 90 authorities in industry, government, and other organizations, together with detailed discussion of papers by persons with varying viewpoints.

Radiological Health

The radiological health program of the Public Health Service has also been expanding rapidly and should become an increasingly valuable source of help in dealing with occupational health and even broader problems of radiation. A special Division of Radiological Health was established last year and is staffed with specialists in both medical and engineering aspects.

Like the air pollution program, the radiological health program conducts and supports research, carries on a training program with courses at the Sanitary Engineering Center and in other parts of the country, and provides consultation and technical assistance to States and communities upon request. Also like air pollution, the program, despite rapid expansion, still lacks sufficient staff and other resources to give as much help as one might wish.

Even if one considers only the occupational aspect of radiological health, its scope and predictable growth are truly formidable:

- It is estimated that 175,000 persons are currently employed in atomic energy industry. Thousands of other workers are engaged in operations involving the use of X-rays and radioactive substances.

- Two thousand hospitals and other institutions are licensed to use radioisotopes for medical purposes.

- A study underway by the occupational health program of the Public Health Service indicates that in at least one industry, uranium mining, the protections now available to workers are not yet adequate. About 64 percent of the miners in the Colorado plateau area, where most uranium mining is done, were found to be exposed to dangerously excessive concentrations, at least fivefold in excess of the desirable working standard.

The rapid growth in the past few years in the number of workers dealing with radioactive materials is as nothing compared with the

growth we shall see in the immediate years ahead. The tremendous task of learning more about the health hazards to the workers involved and of finding effective control measures must be shared by government at all levels and by industry.

Better application of existing knowledge, however, can accomplish much even now. We have recently had a dramatic demonstration of this among our own employees in Public Health Service hospitals. In July 1958, continuous film badge monitoring was initiated in most of the Public Health Service hospitals, outpatient clinics, and field medical units. More than 1,600 film badges have been worn for 1-month periods by personnel working in and around X-rays and other sources of radiation. Analysis of the film badge reports for August 1958-January 1959 indicates a progressive decrease in the number of badges which exceeded an exposure of 30 milliroentgens per week. This exposure is the practical maximum exposure which need not be exceeded by hospital personnel taking necessary precautions. Using this limit, 6.5 percent of the film badge wearers were overexposed the first 2 months and only 0.5 percent in the last 2 months, or a decrease from 31 to 3 needlessly large exposures.

Similar episodes could no doubt be recounted, for almost invariably a real drive to reduce radiation exposure of workers produces impressive results.

We are happy, therefore, to note that the States are exhibiting an increasing awareness and interest in the public health problem of radiation exposure. This is denoted in the increasing number of requests for consultative and technical assistance in coping with radiation problems, ranging from specific technical questions to assistance in development of comprehensive programs in radiation protection. Consequently, the following activities have been initiated in response to such expressed needs:

- Assistance in the development, organization, and operation of State health agency radiation programs. Such assistance is being provided by both headquarters and regional consultants, and, in some instances, by the assignment of trained Division of Radiological Health personnel to States on a full-time basis.

- Consultation on State legislation and rules and regulations for the control of radiation hazards.

- Demonstration projects on public health methods for the reduction of radiation exposure to the public from clinical use of X-rays.

- Technical aid in surveys and monitoring programs designed to determine the amount and effect of radioactive contamination and the extent of radiation exposure to our population.

- Assistance in evaluating the adequacy of proposed radioactive waste treatment and disposal mechanism in reactor facilities and in radioisotopes usages.

- Provision of information to communities near the site of reactor operations including: advice on the protective measures to be employed in connection with site selection; the outlining of laboratory or other radiation measuring methods considered necessary to determine the amount of radioactive contamination or exposure to individuals; and the proper interpretation of the results and effectiveness of various radiation protection methods or decontamination procedures.

The current program is in a transitional stage and, depending on the resources available to it, will develop in the coming months along lines best calculated to aid in the development of State activities.

Particularly significant to the future development of the radiological health program are the hearings which the Joint Committee on Atomic Energy is now conducting. The report of the Public Health Service National Advisory Committee on Radiation also suggests activity levels and assignment of responsibilities. Both documents deal extensively with the respective roles of Federal and State governments.

At the Joint Committee hearings 2 years ago, Merril Eisenbud, manager of the New York operations office of the Atomic Energy Commission, pointed out that one reason why so many unanswered questions about radiation effects exist is that we know so much, rather than so little. "It is simply characteristic of good research that answers beget questions," he said, pointing to the disparity in the funds invested in radiation studies as contrasted with air pollution and other areas. He concluded that

if full information about organic chemicals and heavy metals were available, we should be asking the biologists many of the same kind of questions we are asking them today in regard to radiation effects.

Occupational Health Program Activities

It is imperative that we learn more about the new products that are being introduced so rapidly into general daily use in homes, farms, and factories. We realize, however, that the sheer number of chemicals being introduced each year as industrial compounds or intermediates precludes comprehensive toxicological screening. We in the Public Health Service also recognize that our own research efforts in this area have not kept pace with the problem and its needs. It is our hope that the toxicological and other activities of the occupational health program can be strengthened. The National Health Forum at its meeting in Chicago, March 17-19, 1959, strongly underscored the need for expanded Federal participation in occupational health activities. It particularly stressed the need for more epidemiological studies.

We believe that a first step in protecting the growing numbers of workers exposed to industrial chemicals is basic research to develop more efficient methods of toxicological evaluation. One such need is for the development of adequate testing procedures which will permit prediction with greater accuracy of the effects of long-term exposures. Also needed is the development of diagnostic procedures which, when applied to man, will detect changes long before permanent change has occurred.

The occupational health program has recently begun experimental work in this field of preventive industrial toxicology. The research which resulted in the discovery that vanadium poisoning can be detected by changes in the fingernails long before any clinical symptoms appear is the first fruit of a program that we hope will yield many other equally valuable findings in the coming years.

Another specific activity that we would like to strengthen is the occupational health information exchange. We hope to develop it into a central source of information on the toxicity

of chemical compounds, hazards associated with new processes, disease problems in industry, and control methods. The exchange was started rather recently on an experimental basis and seems to be meeting a long-felt need.

Emphasis will also continue to be placed on field studies, which are indispensable to occupational health progress. At present, the occupational health program has several studies underway which concern large segments of the working population. One of these concerns the effects of industrial noise on hearing, an extremely serious problem intensified by increasing off-the-job background noises. Another study, being conducted jointly with the U.S. Bureau of Mines in the western metal mines, seeks to determine how and where silicosis may be occurring. This problem remains the most significant occupational disease in terms of disability and compensation. Still continuing is the long-term study of radiation effects in uranium mining, to which I referred previously. These are just a few of the field studies which we hope will increase in number and scope.

Everyone in occupational health feels most keenly the great need to improve and expand our mechanism for collecting and reporting information on the health status of workers. Employee health programs, with periodic appraisals of health status, can contribute greatly to such epidemiological research. This is one strong reason, among many others, why we must find ways to reach workers in small establishments with employee health programs.

Basic Approaches

We need to develop a much larger amount of biological content in all programs that involve the environment. This can be done only if the engineer, the chemist, the biologist, the physician, and other specialists operate as a closely knit team.

Such teamwork is being fostered in every possible way within the Bureau of State Services. For example, in the Radiological Health Division, physicians and engineers develop policies and projects jointly. In the air pollution program, although organizationally separated, physicians and engineers share the same office

quarters in Washington and work in the same laboratories in Cincinnati, with the end result that there is joint planning and operation.

To strengthen such coordination at the administrative level, Mark D. Hollis, formerly chief of the Division of Sanitary Engineering Services, has been recently appointed associate chief of the Bureau of State Services. With his assistance as a member of my immediate staff, we expect to achieve an even greater degree of integration in engineering and medical programs. We hope to improve steadily our ability to channel, through our regional offices, whatever combination of medical, engineering, or other specialized consultant services may be needed in developing local programs.

In considering needs for future activity in the fields of environmental health, attention should be given to the published Hearings of the House Subcommittee on Appropriations which were released April 24, 1959. At the request of Chairman Fogarty, Congressman from Rhode Island, Dr. Leroy E. Burney, Surgeon General of the Public Health Service, emphasized the needs in the years ahead:

"In the present stage of thinking, it would seem desirable to establish some centers where orientation would be to particular problems of man in his environment and where research and studies of a specific type of community or industry, or environmental contaminant or influence could be carried out. Within these centers, technical assistance could be made available and training could be given in support of the total public health effort of the various components of the Service and of the States. . .

"Our planning for expansion of program and facilities at Cincinnati in sanitary engineering, air pollution, water pollution, occupational health, toxicology, and radiological health is quite advanced. We do not believe that all of the needs of the Service in these fields can be met at any one geographic site; nor that the total needs of the Nation should be met in Federal governmental facilities. It will therefore be prudent to plan for eventual development of a number of centers, utilizing, where feasible, established educational and research organizations."

Just as the team approach envisioned by Dr. Burney in this statement is the best way to study the complex problems of man and his environment so, I believe, the educational approach offers the best way of getting something done about them. The writing into law of maximum allowable concentrations and other

criteria can some day be helpful, when we are confident what such criteria should be. But more necessary than legal criteria are the educational efforts which prompt labor, management, and the general public to take voluntarily those actions which will contribute to a healthier environment for all.

PUBLICATION AND FILM ANNOUNCEMENTS

The publications and films selected for this list have been issued by or produced for State, local, voluntary, or other organizations associated with public health. Address inquiries to the publisher, sponsoring agency, or distributor.

To Your Health. Film on alcohol and alcoholism presented by the World Health Organization. Designed and directed by Philip Stapp. 16 mm., color, 10 minutes; \$100, including shipping in the United States. Center for Mass Communication, a Division of Columbia University Press, 1125 Amsterdam Avenue, New York 25, N.Y.

Rescue Breathing. Safety film teaching mouth-to-mouth and mouth-to-nose method of reviving suffocation victims. Written, produced, and directed by Lewis and Marguerite S. Herman. 16 mm., black and white or color, sound, 21 minutes, 24 seconds; 1 to 5 prints, black and white, \$110 each; color, \$200 each; reduction for 6 or more prints. American Film Producers, 1600 Broadway, New York 19, N.Y.

Current Research and Development in Scientific Documentation, No. 4. Compiled by Mrs. Madeline M. Henderson, National Science Foundation. April 1959; 85 pages; 15 cents. U.S. Government Printing Office, Washington 25, D.C.

Field and Clinical Survey Report of the Mental Health of the Indigenous of the Territory of Papua and New Guinea. Prepared by Alex. Sinclair, M.D., M.R.C.P., F.R.A.C.P. 1957; 59 pages. W. S. Nicholas, Government Printer, Port Moresby, Territory of Papua and New Guinea.

All the Years. A filmstrip depicting contributions of a community center to the lives of older people. 72 frames, black and white, with record and script, 15 minutes; \$9, including packing and shipping. Leo Seltzer Associates, Inc., 368 East 69th Street, New York 21, N.Y.

The Physician and Labor Health Plans. 1959; 18 pages; 20 cents. American Labor Health Association, 16 East 16th Street, New York 3, N.Y.

Toward Understanding Stuttering. By Wendell Johnson, Ph.D. 1959; 40 pages; 25 cents. National Society for Crippled Children and Adults, 2023 West Ogden Avenue, Chicago 12, Ill.

24 Hours Make a Year. Annual Report of the Council on Alcoholism, 1958-59. 1959; leaflet; no charge for single copies. Council on Alcoholism, Public Health Federation, 312 West Ninth Street, Cincinnati 2, Ohio.

Hints for Programs on Health. June 1959; 10 pages; no charge for single copies. Health Education Council, Public Health Federation, 312 West Ninth Street, Cincinnati 2, Ohio.

A Guide to Public Health Program Accounting. Prepared by the Committee on Program Budgeting and Accounting of the Association of Business Management in Public Health. December 1958; 83 pages; \$1. Mr. Ernest B. Davis, President-Elect, Association of Business Management in Public Health, Georgia State Department of Health, State Office Building, Atlanta 3, Ga.

VA Prospectus, Research in Aging. Transcription of a meeting of the Veterans Administration Advisory Committee on Problems of Aging and guest experts, edited by Dr. Charles C. Chapple. 1959; 125 pages; \$1.50. U.S. Government Printing Office, Washington 25, D.C.

Health in the Mexican-American Culture. A Community Study. By Margaret Clark. Study sponsored by the Rosenberg Foundation. 1959; 253 pages; \$5. University of California Press, Berkeley and Los Angeles.

Urban Sprawl and Health. Report of the 1958 National Health Forum. 1959; 228 pages; \$1.75. National Health Council, 1790 Broadway, New York 19, N.Y.

Radiation: Physician and Patient. Comprehensive film on diagnostic radiology: its biological effects, physical behavior, and proper use in clinical situations. Presented by the American College of Radiology in cooperation with the Public Health Service, supported by a grant from the Rockefeller Foundation. 16 mm., color, sound motion picture, 45 minutes. Prints can be obtained for professional use without charge from: American College of Radiology, 20 North Wacker Dr., Chicago 6, Ill.; American Medical Association, Film Library, 535 North Dearborn Street, Chicago 10, Ill.; Division of Radiological Health, Public Health Service, Washington 25, D.C.; any regional office of the Department of Health, Education, and Welfare, or any State health department.

Calendar of Health Department Events

A SIMPLE CALENDAR devised by the Calhoun County Health Department in Michigan has proved effective in helping all parts of the organization to anticipate forthcoming events.

Serving a population of approximately 142,000, the department has a staff of 32 persons in a ratio of 3 professional staff members to 1 clerical assistant. The total annual budget is less than \$190,000, of which \$165,000 is provided from county taxes by the board of supervisors.

Like its counterparts, the Calhoun County Health Department has certain established programs and responsibilities:

- Laboratory procedures.
- Home and traffic safety.
- Student affiliation.
- Civil defense.
- Staff education and meetings.
- Immunizations by triple antigen and poliomyelitis and smallpox vaccines.
- Reports.
- Mental health.
- Tuberculosis.
- Crippled children, school children, and maternal care.

In addition, there are established programs which must be accomplished on a seasonal basis within a short period of time, such as:

- Topical application of fluoride.
- Spring cleanup.
- Food establishment inspection.
- Trailer park and camp inspection.
- Immunization of school children.
- Nursing home inspection.
- Participation in meetings.

The department is also called upon to participate in certain campaigns and community activities which not only have value in themselves, but assist in the establishment of community

rapport. Examples are annual drives directed to public knowledge of diabetes, farm safety, fire prevention, spring cleanup, Christmas safety, and mental health.

The schedule of events entered on the calendar allows employees to evaluate the prospective workload at a glance. It gives a quick view of the periods of the year filled with scheduled activities and periods which conceivably may be used to develop a new program or emphasize existing programs.

Once it is fully determined that a scheduled program or event no longer has public health significance, it soon yields its place on the calendar to others.

The calendar is especially useful in planning public information campaigns, allowing time for gathering new and pertinent information and evaluating past procedures.

Also each division in the department becomes aware, in general terms at least, of the anticipated activities of other divisions, through use of the schedule of events. It alerts officials in many instances to opportunities for cooperation between divisions that might not otherwise be explored. Public health nursing and sanitation activities in particular have been coordinated by this process, so that they may share effectively in information services, or perhaps time their use of laboratory facilities at periods that are opportune.

A sample of the calendar, reproduced on facing page, is modified to meet the mechanical limitations of the printed page. The calendar used at Battle Creek is constructed to permit each user to write in a new or temporary project.

—GEORGE M. WATSON, M.S.P.H., consultant in health education, Calhoun County Health Department, Battle Creek, Mich.

NATIONAL
HEALTH
FORUM

mental health

of
the
worker

Mental health in industry was the subject of two panel sessions at the National Health Forum, held in Chicago, March 17-19, 1959, under the sponsorship of the National Health Council, with "The Health of People Who Work" as its general theme.

Participants in the panel discussion were: Dr. David H. Goldstein, medical director of the *New York Times*; Dr. Kenneth Munden, psychiatrist in the division of industrial mental health, Menninger Foundation; Richard C. Warren, director of education and personnel research, International Business Machines Corporation; Dr. Alan A. McLean, psychiatric consultant, International Business Machines Corporation; Dr. Ralph T. Collins, psychiatric consultant, Eastman Kodak Company; and Dr. James C. Conant, psychologist, Hanford Atomic Products Operations, General Electric Company. Dr. Collins and Dr. McLean were chairmen.

MENTAL HEALTH in industry presents a challenge to management. This challenge is no longer obscure. People have become quite familiar with the costs of treating the mentally ill, the shortage of trained psychiatrists, and the actions taken by many States in an attempt to improve the therapy of those stricken with mental illness and to further research into its causes.

Chairman Collins made these statements in opening a discussion of mental health in the industrial setting. He added the following facts:

- Emotional illnesses cause more absenteeism from work than any other illness except the common cold.

- Eighty to ninety percent of dismissals today are attributed to social incompetence, the inability to get along with people. Ten to twenty percent of dismissals are defined as technical incompetence.

- One of four workers, or 16 million of 65 million, manifest personality disturbances through absenteeism, accidents, alcoholism, illness, job dissatisfactions, or trouble with co-workers and supervisors.

- Off-the-job stresses loom large in the causation of on-the-job dissatisfactions, ineffectiveness, poor work habits, ineffectual relations, and faulty attitudes.

- The cost to industry of the disruption resulting from emotional disturbances among workers, supervisors, and executives runs into hundreds of millions of dollars annually.

- Leadership in the office and factory is a vital force in the promotion and preservation of mental health in the environment of the worker at any level.

- If he is to be a good leader, the health of the executive must be conserved, and yet today there are many pressures, frustrations, fears, and feelings of insecurity in his life. Consider the titles of some recent articles in business and popular magazines relating to the hazards of being an executive, such as "Slow Up or Blow Up," "Your Next Promotion Can Kill You," and "Must Executives Die Young?"

Collins underscored the importance of the total health of the worker, both physical and emotional, to the worker himself, the company

which employs him, and to his family and community.

Occupational Medicine

The objective of occupational medicine is to keep the working force as healthy and therefore as effective as possible, Goldstein said. And he added that the keystone of health maintenance is preventive medicine and case-finding.

In casefinding covering the whole host of physical and mental diseases, the plant physician is concerned primarily with early detection, particularly in mental illness, Goldstein continued. He knows that the earlier detection is achieved, the more likelihood of cure or if not cure, substantial amelioration, and the less disruption in the industrial community.

Goldstein described the plant physician as an unusual combination of personal physician to the employees during their working hours and health officer for the plant as a whole. In both capacities, he observed, there is opportunity for early detection of mental illness. As personal physician, he can relate physical and emotional stress to the total medical problem as employees seek his assistance, and as health officer, records and statistics permit him to observe, epidemiologically, the areas of excessive absences, accident frequency, or increased frequency of visits to his department.

As a means of casefinding in mental illness, Goldstein emphasized the advantage of educating supervisors to recognize symptoms. Support for this program, he said, should include a halt for medical appraisal, after a reprimand and before disciplinary action. The appraisal should be preceded by an interview with the supervisor. Deterioration in worker performance, especially when associated with personality change, always warrants referral to the medical department. He also pointed out the advantages of screening morbidity data for depressions masquerading as spastic colon, palpitations, fatigue, and noticeable weight change.

But the responsibility of the physician in industry goes beyond detection of mental illness alone into the broader area of prevention, Goldstein continued. As a member of the plant

community, the physician is free to discuss work attitudes and climate and, through these discussions, obtain understanding of human relations in the various departments. He appreciates the importance of and observes group behavior. He is aware that many companies have a "plant personality" to which employees attempt to conform.

Company policy, according to Goldstein, may invite employees of the type who thrive in a dependency relationship. Disturbances in supervision or job assignment of these dependent personalities may well develop stresses or even breakdown. He suggested that anticipation of such situations permits preventive measures.

In discussing the present emphasis on the executive position as a health hazard, Goldstein said scare headlines are "a bit overdone." He cited the results of a recent study by a large corporation, using heart disease, hypertension, and arteriosclerosis as stress manifestations, which showed an incidence somewhat lower in executives than in rank-and file workers of comparable age and sex. He prefaced his remarks in this regard, however, by saying there is a rather extensive executive health program in operation at his plant and mentioning the value of the health appraisal and counseling part of these examinations.

In adopting what he termed a tangible and concrete approach to possible solution of certain mental health problems in industry, Goldstein discussed some of the specific procedures used by his company.

We must realize that throughout the United States the predominant occupational health service in industry is provided by the nurse, working alone, Goldstein said. It would be blind indeed, he added, to concentrate on the large plant medical service with an elaborate staff.

Through recognition, the nurse can take the first steps in handling employees with mental illness, he continued. If a doctor is available, either on call or on a part-time basis, she gives him a history of her reasons for referral. If she does not have a plant physician available, she can reach the employee's family physician, alert him to the situation, and at the same time encourage the employee to see his doctor. Both elements were considered essential by Goldstein.

The nurse has a variety of community resources available, he added, if the family physician is unwilling to assist or feels unequipped to handle psychiatry, if there is no family physician, or if the employee cannot pay for help. But her fundamental role is to recognize emotional disturbance and to encourage the employee to seek help.

He emphasized that the employee with mental illness must reach out for help; he cannot be directed to seek it.

In citing specific examples of help given by a medical department, Goldstein discussed first the "ever-present and too common" problem of alcoholism. In his plant, he said 2½ percent of the employees are identifiable alcoholics. He added that there are probably more, unknown to him.

Alcoholics have a tremendous need to see themselves in relation to people, he said, and we try to harness this motivation through a firm yet gentle approach, saying "Let's be realistic, you have a problem. Here are the avenues of help." In the case of a recognized problem drinker, Goldstein continued, job jeopardy is used in a system of warnings, in the hope this will motivate the man to seek assistance.

Sources of help suggested by Goldstein were the family doctor, Alcoholics Anonymous, and community resources. While listing the family physician as the frontline of defense in considering community aspects of depressions and severe psychoneuroses, Goldstein added that for the most part he will not assist in treatment of alcoholism.

Preventive psychiatry appropriately used was discussed by Goldstein as another example of good mental health practices in industry. Retirement shock is a familiar term today, he said, stating that it is his belief that the dazed, apathetic, and withdrawn attitude of individuals verging on retirement or newly retired can be avoided through counseling. His organization, he said, routinely schedules informal discussions with employees between 6 months to 2 years prior to retirement. The individuals without resources outside their job are the most likely candidates for retirement shock, and it is these individuals who can be helped through counseling.

Goldstein explained his company's procedures in the return to the work area of a patient cured of a mental illness. He elaborated on the consultative techniques between the hospital psychiatrist and the plant physician in evaluating the demands of the job, saying that the advice of the psychiatrist is followed in most instances, in modifying either the work itself or the hours of work. He pointed out that these efforts are not always successful, but without these techniques, the patient might never be returned to work.

Goldstein recognized that there are only a handful of industries in the United States employing a psychiatrist full time. Recognizing that it would not be practical for many to do so, he advocated use of the part-time psychiatrist on a consultative basis.

Considering that the use of community resources is dictated by cost and the limitation of employee's funds, he saw encouraging developments in the area of insurance, such as major medical care programs and group policies, taken out by labor and management or management alone or paid cooperatively.

Goldstein stressed the importance of preserving the confidential nature of medical information in a company setting. Obvious outbreaks cannot be concealed, but referrals for subtle manifestations must be preserved as a confidence. The value of maintaining this information as privileged was related by Goldstein to the number of employees coming to his department for help.

While it is axiomatic that the industrial medical department appreciate its responsibility in the area of mental health, Goldstein said, it is equally axiomatic that if the whole program is to succeed, management must endorse and support the medical department.

Research

There are two ways of looking at mental health problems in industry, Munden said.

We can enumerate symptoms, such as those implied in alcoholism, absenteeism, accident proneness, promotion neurosis, and occupational reactive depressions—a palliative and purely symptomatic approach not in keeping

with medical tradition that diagnosis precedes treatment.

Or we can look beneath the surface at the forces in industry which tend to impair mental health, such as failure to provide identification models, interference in interpersonal relationships, or demands on people beyond their individual capacities or skills with a resultant failure to come to psychological fruition.

Munden related these forces, which he said precipitate symptoms through deflating self-esteem to a feeling of worthlessness, to three factors: reluctance to act, power relationships, and the impact of change.

He mentioned perceptive executives, who understand the effects of motivation very well but who hesitate or are reluctant to put their knowledge to use by satisfying the desire to be heard, to be recognized. The classic denial of opportunity for individual recognition persists along with the custom of giving a watch for 30 years of service, even under an informed management.

Failure to recognize the meaning of power held over others creates another problem area, Munden indicated.

Living is a system of power relationships and dependencies, he said. We start life dependent upon those more powerful than we—our parents. From then on, any person in a position of authority is the "father figure."

People have conscious expectations of being protected, helped, supported, and guided by the authority figure. They also have unconscious expectations of which neither they nor the person in power is aware. Knowledge of such power relationships and their proper use means that a supervisor appreciates his role fully.

Technological changes are occurring so rapidly that it is difficult to keep up with them, Munden said. It is assumed that people can change as easily, accepting the dictum, for example, that automation does not mean loss of a job and that there will be no fears and anxieties or disbeliefs of such a dictum.

He pointed out the example of the difficulties of middle-aged people in accepting changes in job techniques or increased responsibilities, their feeling being that they cannot change, even while they complain.

The Health of People Who Work

Sponsored by the National Health Council and its more than 65 member agencies, the National Health Forum on "The Health of People Who Work," held in Chicago, March 17-19, 1959, was attended by approximately 600 persons from the States, Hawaii, Puerto Rico, and Canada.

Seventeen groups discussed such areas of occupational health as provision of a healthful working environment, preparation for retirement, mental health, health education, communication, mobilization of resources, programs for small plants, and costs relating to worker health. At the close of the 3-day meeting, representatives of labor, management, the professions, and the voluntary and official agencies summarized suggestions for improving the health of workers, their families, and their communities.

Throughout the sessions, an underlying theme was the need for new colleagues—from management, labor, the health professions, and the voluntary and official health agencies—to join the

industrial physician, hygienist, and nurse in the common interest of occupational health.

It was forcefully brought out that official agencies, national, State, and local, have not yet developed adequate programs in the field of occupational health. Among other recommendations, speakers urged that sufficient funds be allocated; that all official agencies, as employers, provide occupational health programs for their employees, thereby setting an example for voluntary agencies and for private industry; that official agencies take a more active part in conducting multiple-industry, large-scale epidemiological studies; and that guidance be given especially to the development of occupational health programs for employers with relatively small numbers of employees.

A full report, entitled "The Health of People Who Work," based on transcript records of discussions by the more than 200 specialists attending the forum and edited by Albert Q. Maisel, is scheduled for publication by the National Health Council in October 1959.

Munden stressed the error of treating symptoms as problems. He emphasized that this in itself is one of the biggest hazards to good mental health practices in industry.

He warned industry against placing matters of human relations in the hands of nonexperts. These nonexperts have lives entrusted to them, holding power over the occupational future of individuals, he said.

Get help when interested in employees who come to you with troubles, Munden urged. Mental health problems cannot be tackled alone.

As a typical situation, he cited the industrial nurse who has to deal with employees drifting in and out, obviously seeking something and taking up her time in aimless conversation. She can't change the world and the plant by herself, he said, but she respectfully can demand aid. He said local mental health agencies would respond, naming State hospitals as a source of psychiatric assistance on a consultative basis.

Munden admitted that few psychiatrists are

interested in the industrial area, since their first interest is in cases. They will take a referral but are reluctant to visit a plant and discuss mental health practices.

Techniques used to stimulate interest in industrial psychiatry at the Menninger Foundation were described by Munden. He said that about 10 percent of psychiatric residents in this country are trained at the Menninger School of Psychiatry. A seminar on industrial psychiatry was initiated in 1955 and has been held yearly since then. Interest was shown but the reaction was negative on the whole. In 1957, visits by residents to nearby plants were begun, with the cooperation of the medical departments. Most residents were amazed and responded positively to this new program orientation.

Munden suggested that this approach would be useful in stimulating interest among local psychiatrists and mental health associations.

Recognize the problem and get the help available, was his closing admonition.

Education

An industrial setting is not appropriate for direct psychotherapeutic activity, Conant said. It is a place where we can identify problems and see that proper care is prescribed. It is in the more important role of prevention that the psychologist makes his contribution, he stated. The industrial community inherits the problems of its society. Since mental health is one of society's major problems, so it is industry's. People bring to work their cares and anxieties, their alcoholism, and their concern about their children. The industrial social order can provide gratifications which reduce these stresses or it can nurture dissatisfactions, which become imbedded, take root, and flourish in the industrial soil. The objectives of an educational program are to aid in providing the knowledge and tools to create a desirable atmosphere.

Conant emphasized the importance of management decisions on the mental health climate. Even casual comments often are taken quite seriously. He cited the example of the manager who indicated to one group that their house-keeping could be improved. Several groups immediately set other work aside to clean house, irrespective of priority, because "the old man is on a house-cleaning kick."

Thought given to the effect of management decisions can be a powerful tool in improving the climate and lessening the aggravation of people's emotional problems.

Another problem area was labeled by Conant as that of "conflicting needs." He referred to management's attitude of "what's good for the organization is good for the people," without recognition of the divided loyalties and conflicting needs of people. In citing examples, he told of the manager who gave a low rating to employees who left exactly at closing time, thereby imposing an unrealistic standard in view of their responsibilities to their families and communities. He also mentioned the people who, though paid on a piecework basis, curtail their production rather than incur criticism by their peers.

We sometimes make people feel anxious and inordinately guilty, Conant said, oftentimes quite unnecessarily, by failure to recognize their conflicting needs and to help in resolving them.

Conant said the training program at his plant is aimed at three levels of understanding how people think, feel, and act.

The orientation course, labeled "Understanding People," includes seven 2-hour sessions once a week. An additional session at the initiation of members is called a "self-analysis experiment." With their full consent, members anonymously take a personality test. They also predict their individual scores on ten traits, based on guides that are provided. They then indicate what they wish they were like. The answers yield a self-concept and a concept of ideal self, in addition to the test results.

The test results provide a fairly accurate measure of what the individual members are like in relationship to people in general, he continued. It is followed by individual discussions to interpret the results. Personal problems can be discussed and counseling or referral for treatment given.

Conant stressed this is not a technique-oriented or "how to" type of training. Rather it aims at greater insight into behavior and allows for individualization of approach. As supervisors and managers understand human needs better, especially the impact of their own psychological makeup, they are better able to establish a work climate conducive to more effective adjustment. From management's viewpoint, increased productivity and creativity are significant by-products.

The second course, "Interviewing Techniques," is designed to improve skill in handling people, Conant continued. He said much of the work of supervisors and managers requires the ability to "bridge the perceptual chasms of our experience and their experience." The training given is designed to help people learn to listen, to help them realize when they are not listening, and, if possible, to understand why they have not listened. Interviews are role played, tape recorded, and then analyzed by the group. Recorded examples are also played to demonstrate how someone else handled the situation.

As a result, the group becomes extremely sensitive to the importance of interpersonal dynamics, not only to the words spoken but to the facial expression, gestures, and mannerisms

which indicate whether or not the other person is listening, Conant said. The course is very popular with management, he added, mainly because they feel they learn techniques in two-way communication and in giving emotional first aid. He said guidelines are given for not "getting in too deep," and emphasized that the medical department is always available for consultation and referral.

The third course, still in the trial stage with a volunteer group of 10 persons, Conant described as a workshop in self-understanding. It attempts to get even farther away from the "how to" type of presentation and more into the "why" of behavior. The course provides "situations" and then assesses reactions to each of them. Discussion is devoted to comparison of the different reactions among the group members. The purpose is to show the importance of a person's attitudes on his interpersonal relationships—his impact on others, and the impact of others on him; the role of unconscious motivations in behavior; and the effect of childhood experiences on the development of personality. Preliminary results are encouraging.

Conant said 60 percent of his time is spent in training, and he reviewed the various ways training leads him into consultation with management; assessment of employee morale, consultations about individuals, personal counseling, employee relations problems, and the like.

In summary, Conant said he feels psychologists within the industrial medical department are making pioneer strides in preventive mental health which in 10 years will bring advancement in this field throughout large industrial concerns.

The Management Viewpoint

I think every management development program is directed toward a climate conducive to minimum frustrations and maximum effectiveness on the job, Warren said. Certainly, efforts to define jobs, to determine areas of authority, to establish performance criteria, and to improve man-manager relationships are attempts to let the worker know where he stands and feel more secure in his position and in his

relationship with his co-workers in the plant and in the management hierarchy.

One of the questions plaguing management in its efforts to run a business with healthy people is, "How sick is sick?" he said. No one is completely healthy mentally: it is a matter of determining the optimal degree of mental health within any organization.

Warren challenged the assumption that 1 of 10 persons need treatment. Use of these figures is equivalent to lumping the common cold with tuberculosis, he said. In a preventive mental health program, we should address ourselves to cases that give evidence of being acute, rather than trying to be all things to all people.

He admitted the difficulty of providing guides to a manager in the early detection and referral of incipient mental illness. In so doing, he said, we must preserve the primary function of business, avoiding a climate of "mental hypochondria." We must not permit overtones of mental illness to so becloud personnel actions as to make administration all but impossible.

An educational program in the prevention of mental illness within his company was described by Warren, who credited McLean as its creator. Endorsement of the program by division general managers was obtained before it was inaugurated in plant areas, he said.

Essentially, the program seeks to alert management at all levels to the facilities which can be brought to bear in dealing with a disturbed worker and to provide guideposts for managers in referrals. Managers attended a series of conferences on mental health which included on the program the professional psychiatrist, the plant physician, the plant personnel manager, the psychologist, and the plant general manager. The desired result was obtained, he said, since they presented a concerted story on mental health with the backing of the professional staff and management.

Management can do much, he added, to improve mental health through internal research within the company and widespread dissemination and use of the results of research being conducted outside the company. By making full use of these experiences in decisions and establishment of policy, Warren said, management is leading from as much strength as it can.

Psychiatry's Role

Some mental health problems at work are obvious and easily recognized, McLean stated. Incidence of mental illness, environmental influence on the emotionally disturbed employee, and loss of productivity, income, and manpower are in this category, he said.

But there are other less clearly recognized factors, he added. They range from the meaning of work to the individual to the more subtle factors in a work situation which may trigger, not cause, symptoms of mental illness. They encompass the mental health of individuals at work but are not regarded ordinarily as doing so.

McLean referred to Conant's discussion of the anxiety aroused in employees through policies, procedures, situations, and even personalities within a company. He said promotions, demotions, job transfers, and assignments with a different supervisor can be contributory factors in mental illness.

As an example, McLean cited the case of an executive who, on returning to work after a physical illness, was promoted to a position of greater responsibility. He reacted with a major depression requiring months of hospitalization and care. The executive, insecure as a result of his physical illness, was given no alternative but to accept the promotion, which obviously contributed to his breakdown.

Learning a great deal more about why and how changes on the job influence mental health becomes one of the major problems in industry today, he said.

No psychiatrist in industry can function successfully without management's support. Neither can he function optimally without skilled and perceptive physicians in the medical department or medical consultants fulfilling this role in the community. And no mental health program can succeed without emphasis on both education and research, McLean concluded.

Psychiatry's role in industrial mental health is relatively new, Collins said.

Tracing the work of pioneers in the field, he said the first psychiatrist in industry, Dr. C. Charles Burlingame, started with the Cheney Silk Mills in Manchester, Conn., in 1914. Dr. E. E. Southard, professor of psychiatry at Harvard, worked with the Engineering Foundation

in 1920 on a number of surveys. And from 1925 to 1929, Dr. V. V. Anderson, as a consulting psychiatrist with Macy's Department Store, defined job qualifications and job placement, matching these factors to personality, job, and dexterity capabilities. He also did considerable work in emotional and followup therapy, with the assistance of visiting and public health nurses, and, at the same time, wrote "Industrial Psychiatry," the only textbook ever published on the subject.

During World War II, industry called on psychiatrists to assist in getting out the product and bolstering morale, Collins recalled. But this was a temporary expedient resulting in dismissals at war's end.

Later came the new era in mental health programs in industry, when psychiatrists were hired on a sound medical basis, he said.

Today the psychiatrist plays many roles in industry, with his own and other companies, with local and national mental health societies, with personnel and supervisors, Collins stated.

He emphasized the role of the psychiatrist as a teacher. Nurses, physicians, and supervisors learn to interpret employee behavior from the psychiatrist. They learn that it is not a personal attack when a patient glowers, is sarcastic, and shows hostility. They are taught they stand for something in the patient's life and experience which has brought on revolt. And they are taught to listen. Collins said professional medical personnel are trained to be active, to do things, and to order patients to do things, and they question the value of just listening. The psychiatrist teaches them to listen without prejudice or bias.

Counselors working in an ancillary capacity to supervisors urge troubled employees to seek the advice of the supervisor and the medical department. The psychiatrist does not see anyone unless referred by the medical department, he added. This avoids putting diagnostic responsibility on the shoulders of the supervisor. Otherwise word is likely to get around the department that "you'd better go easy, or Joe will send you to Collins and he'll pick your brains." This is not good mental health or education.

Collins said psychiatrists have a responsibility to further education in industrial

psychology outside the company area. A questionnaire sent out in a magazine asking for information from those interested in the subject brought more than 180 replies from psychiatrists working about 2 hours a week as consultants in industry.

The psychiatrist in a community is also a citizen, Collins stated. He illustrated the value of the assistance given local mental health societies by referring to the Camden Mental Health Association which invites supervisors to attend monthly meetings on such subjects as

"Understanding Your Emotions." By methods such as this, psychiatrists help management to understand behavior.

Most psychiatrists agree there is need for greater awareness of individual needs by management and medical personnel in industry, McLean said. Understanding the fundamentals of normal personality functions can bring greater understanding of much unexplained behavior. And if applied, it can lead to a healthier company and a healthier individual within its organization.

Epidemiological Notes

Clostridium perfringens

A food poisoning episode occurring under nearly ideal conditions for expert investigation has yielded a clue which may enable health officials to determine the cause of similar outbreaks in the future. At present, the causes of about 100 of the more than 200 food poisoning episodes reported annually in this country are unknown.

A species of bacteria known as *Clostridium perfringens* was identified by the Public Health Service in both food and human specimens collected during the investigation of the episode. These bacteria are reported to account for about 25 percent of food poisoning cases in England but have not been considered a hazard here and consequently are not included among the bacteria most laboratories are equipped to identify.

The episode which yielded the new clue occurred on April 8, 1959, aboard a Washington-bound train from Toledo, when more than 100 delegates to an AFL-CIO conference on unemployment complained of stomach cramps and diarrhea several hours after eating a turkey dinner.

Because the outbreak occurred on an interstate carrier and thus came under Federal jurisdiction,

the Public Health Service as well as the District of Columbia Health Department sent specialists to the scene shortly after the first symptoms were reported.

Samples of food were sent to the milk and food research laboratories in the Robert A. Taft Sanitary Engineering Center in Cincinnati. Subsequently, specimens collected from crew members and several passengers were also tested in these laboratories.

At the same time, an epidemiological investigation was conducted by epidemic intelligence officers from the Communicable Disease Center in Atlanta. This investigation included a questionnaire which was sent to 450 passengers to obtain more details about the episode. Of the 300 who replied, 160 listed symptoms indicative of *C. perfringens* food poisoning.

Laboratory findings correlated almost exactly with the clinical findings. *C. perfringens* organisms, as well as large numbers of enterococci bacteria, were found in samples of the turkey dressing.

Since some authorities believe that large numbers of either of these organisms may cause the same type of food poisoning, the Service has arranged for additional tests by the Walter Reed Army Medical Center in Washington and by Dr. Barbara Hobbs, an expert on *C. perfringens*, in London, England.

It will be several months before these additional tests are completed. However, the findings of *C. perfringens* in this outbreak has led to speculation as to whether it may be a frequent cause of food poisoning in the United States. The Public Health Service has alerted health officials to use Service facilities to check suspect outbreaks. It is also developing information materials, since there is little on this subject in American medical and public health literature.

Florida's Citizens Medical Committee on Health

RECOMMENDATIONS

WILSON T. SOWDER, M.D.

RECOMMENDATIONS for strengthening health programs and services in the State of Florida were submitted to the Governor by a Citizens Medical Committee on Health in January 1959. The committee was appointed by the Governor in April 1958 at the suggestion of the State medical association. It had 22 members, 18 of whom were physicians, all but 3 in private practice. There were two legislators, a hospital administrator, and the executive secretary of the State medical society.

Including meetings of the four subcommittees, there were seven sessions, all with virtually a 100 percent attendance. A variety of detailed studies were outlined by the committee and conducted with the aid of a designated staff. The recommendations were evolved by subcommittees and as revised had the unanimous approval of the committee as a whole.

It is practicable here only to outline the nature of the studies and of the recommendations. For those with particular interest, a limited supply of the published report is available from the State health officer, Jacksonville, Fla.

Chronically Ill and Aged

One subcommittee directed its attention to the medical care of indigents with chronic diseases and to the health and care of the aging.

As an example of studies conducted, there was a complete survey of all inmates of nursing homes and of the nature of the care available in these homes. There was a study of 8,474 representative hospital admissions and of 1,590 patients who remained in general hospitals for 15 days or more. Outpatient services currently available in the State and the nature and distribution of available ancillary home care services were examined. These studies resulted in nine recommendations which began as follows:

"Though this committee has directed its attention predominantly to provision of medical care to the chronically ill and aged, it recognizes and emphasizes the importance of health promotion . . . [It encourages] a wider and specialized interest by medical practitioners and health officers in the health needs of the aged." The recommendations continue:

"In this country it is accepted that the responsibility for medical care rests properly with the individual and family, with services provided by freely selected physicians. An essential element of this plan is prepayment and distribution of costs through voluntary insurance. . . . It is, therefore, recommended that through every practicable channel the medical

Dr. Sowder, a member of the Citizens Medical Committee on Health, is the health officer of Florida.

societies and official agencies encourage the development and promote the use of voluntary medical and hospital insurance which will extend benefits to the aged and cover other than short-term illnesses. . . ."

There was a long and detailed recommendation pertaining to the development of ancillary home care service. It was recognized that insofar as practicable the aged and those with chronic diseases should be cared for in the familiar environment of the home. The recommendation emphasized the responsibility of both the official and voluntary health agencies in developing and providing home nursing and rehabilitative services.

Individual recommendations pertained to the provision of outpatient care of chronic diseases, to the improvement of nursing home care, and to the provision of hospitalization for the indigent. These recommendations were designed to meet specific needs revealed through the studies of the committee, and the methods recommended involved extensions or modifications of programs now in effect in the State. There were some original approaches; for example, the recommendation "that a conference of church leaders be convened by the Governor to explore and define the responsibility of Florida's churches in providing services to the aged." Specific recommendations as to the respective roles of the State board of health and the State department of public welfare in the provision of medical care were offered. The committee held the opinion that the responsibility for the administration of programs of medical care should be in the hands of the medically directed department. Cooperative planning to this end was urged.

One recommendation clearly revealed the broad outlook of this committee: "It is the guiding conviction of this committee that responsibility for the health and medical care of the indigent should be centered as close as practicable to those to be served." The committee discussed tax sources which would permit the State and the local community "to plan and support medical and health services in accordance with programs evolved by the State to best meet its needs." It mentioned the possibility that the social security program might permit States to combine the present programs for

medical care to the categorically indigent into a single medical program administered by a single health agency.

State Agencies

A second subcommittee gave detailed attention to the medical and health services provided by the various State agencies. The purpose was to reveal any unnecessary overlapping of activities or any deficiencies and to consider possible improvements in plans for the administration of all State medical and health programs. In the main this subcommittee offered a commendatory report with helpful suggestions. It stated:

"The committee is favorably impressed with the variety and amount of needed medical and health services provided through official agencies to the people of Florida. They commended the agencies for the generally smooth and effective cooperative relationships. There is no significant amount of overlapping or duplication of services at State level. With a program distributed through 13 agencies there could be obvious imbalance but this was not evident. Despite these generally favorable observations, it also is clear that there are possibilities for improvement in organization and in operations."

A general recommendation of the committee was that in future planning any wider dispersion of medical and health responsibilities should be avoided. Future development should be in the direction of consolidation. Two specific recommendations dealt with tuberculosis; one pertained to medical care in the State prison system, and another emphasized the urgent need for improved facilities for the institutional care of the mentally ill, particularly for the care of psychotic children.

The committee expressed dissatisfaction with the diverse nature of plans for the provision of hospital and medical care to eligible individuals at State expense. It was their hope that similar procedures could be evolved in programs for the provision of medical care to the categorically indigent, the medically indigent, crippled children, those being assisted through vocational rehabilitation, and others provided care at the taxpayers' expense. Attention was

given to the school health program, which they considered appropriate and satisfactory, and to the urgent need of increasing activity in accident prevention. Three recommendations are of such interest to public health that they are reported in the words of the committee:

"While fully acknowledging the necessity and importance of public welfare the committee is gravely concerned with the seeming lack of any defined limits to the activities of welfare agencies. Any worthy project can be conducted in the interest of public welfare. This committee is convinced that health and welfare agencies have different and distinctive missions and that there must be a proper assignment of responsibility and authority, particularly for medical and health services. The committee holds that services provided by the medical professions and particularly for medical care in or out of the hospitals should be the responsibility of medically directed organizations. It is to be emphasized that in these activities a close working association with the medical professions must be established and maintained, and that medical judgments are essential for sound administration. While the detailed planning of inter-agency relationships is beyond the scope of this committee's activities, it does recommend further study and consultation by the agencies involved to define areas of responsibility for medical and health problems in the public welfare, public health, and in other State agencies. This is considered essential as a basis for sound and productive cooperative working relationships.

"While there is at State level a dispersion of responsibility for broad medical and health problems, this committee holds strongly that at the local level there should be a consolidation of all community health programs for the protection and promotion of health, physical and mental. It is noted with satisfaction that the department of education and the board of health through joint planning have evolved commendable plans whereby the county health departments give the health services needed in the school health program. It is recommended that other agencies, particularly the Crippled Children's Commission, the Council for the

Blind, the Industrial Commission, and the alcoholic rehabilitation program, consider comparable programs. In the opinion of this committee, the county health departments should be so strengthened that local health services needed by various State agencies could be provided through sound cooperative planning and action. In view of the costs of travel and the maintaining of multiple regional offices, the committee is satisfied that the recommended consolidated activity at the local level will result in savings and in increased efficiency.

"It is recognized that the present sound pilot programs for the treatment and prevention of alcoholic addiction are designed to evolve effective measures which eventually may be applied on a county or community basis. Since the future hope is for effective prevention it is recommended to this end that consideration be given to developing at an early date a local pilot preventive program incorporated as a part of the activities of some selected county health department."

Other Recommendations

The study of the voluntary health agencies was revealing. It had not been appreciated that the income provided voluntarily by the citizens of the State for health programs materially exceeded the total appropriations from all counties for public health work. While the committee recognized the importance of the work of voluntary health agencies, it appeared to them that activities would be more productive with effective coordination among the voluntary health agencies themselves and with closer cooperation with the professional societies and public health bodies. There was concern with the multiplication of voluntary health agencies, and it was recommended that for the protection of the public's investment and the favorable reputation of the agencies some appropriate registration and some public accounting and reporting be required.

Attention was given also to possible means for attaining a more effective distribution of medically trained and ancillary personnel.

Concerning one of the newest health problems, it was recommended that a medical committee on radiological safety, a majority of

whose members would be qualified radiologists, be designated to serve in an advisory capacity.

Conclusion

These broad and comprehensive recommendations are of particular significance since they come from what is usually considered to be a rather conservative professional group. It is

a source of gratification that a representative group of practicing physicians in Florida who were appointed by the Governor in response to a suggestion of our State medical association committed themselves to such a liberal and progressive public health program. It is expected and believed that their recommendations will be given serious consideration in the months and years ahead.

PHS exhibit

The Migrant Worker

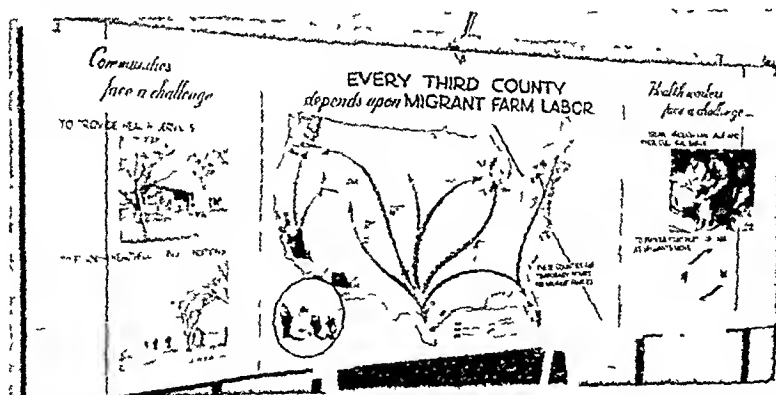

Information supplied through this new Public Health Service exhibit on migrant workers is designed to encourage organized community effort in meeting the health problems of domestic agricultural migrants on a continuing basis.

The exhibit emphasizes the challenge to communities of providing adequate housing and health care as well as the challenge to health workers in overcoming language and

other cultural barriers to communication with migrants, and in developing methods of providing continuity of services as they move.

Designed for display at national, regional, and State conferences, and other places where interested people gather, the exhibit is available for loan without charge, exclusive of shipping charges.

Further information, including arrangements for borrowing, can be obtained from the Program Development Branch, Division of General Health Services, Public Health Service, U.S. Department of Health, Education, and Welfare, Washington 25, D.C.

Specifications: A 3-panel exhibit on legs, 7 feet high, total weight 375 lbs., including the packing crate, center panel 4 by 6 feet; each of the side panels, 4 by 3 feet, attached to the center by hinges. Lighting fixtures are attached to the panels at the top, and the three 300-watt reflector floodlights can be connected with a single outlet.

1958 Summary of Disease Outbreaks

CARL C. DAUER, M.D., and DONALD J. DAVIDS

THE PATTERN of foodborne and waterborne disease outbreaks in 1958 did not differ greatly from that of the previous years (table 1). However, a closer inspection should be made of some aspects of the pattern. For instance, there is no convincing evidence that staphylococcal food poisoning and foodborne *Salmonella* infections are becoming less frequent.

The decline in number of outbreaks and cases of staphylococcal food poisoning reported in 1958 and in 1957 compared with previous years is more likely to be due to failure in reporting than to a reduction in this type of illness (table 2). Two outbreaks involving cheese were among the reports received in 1958. In one outbreak cases occurred in two adjoining States receiving shipments of cheese processed in another State. Staphylococci were isolated from samples of the cheese obtained from the distributor and the factory. Furthermore, the organism was found in milk from dairy herds supplying milk to the cheese factory. Some strains of staphylococci isolated from samples of milk were resistant to certain antibiotics. The second outbreak occurred in an institutional population that had been supplied with cheese manufactured in the same State.

A review of reports received in past years shows that staphylococcal food poisoning associated with fluid milk, dried milk, and cheese is not uncommon. It is also known that bovine mastitis caused by staphylococci is common. Furthermore, the indiscriminate use of some

antibiotics in the treatment of mastitis has favored the development of strains of staphylococci that are resistant to the antibiotics. Therefore, there is need to investigate more thoroughly many aspects of the whole problem of staphylococci in milk and milk products and to study the relationship between staphylococcal infections in man and animals. More intensive studies of outbreaks should also be made when milk or milk products appear to be vehicles of infection.

Fewer cases as well as fewer outbreaks of foodborne *Salmonella* infection were reported in 1958 than in 1957. The numerous sources of infection reported emphasize the wide distribution of these organisms, particularly in animals and animal products, such as meat and eggs (table 3). In one outbreak caused by *Salmonella dublin*, infection was traced to a certified raw milk dairy. Laboratory examination revealed the presence of this organism in specimens of feces of a dairy farm employee, but *Salmonella* organisms were also isolated from three cows in the dairy herd. In another State, employees on a dairy farm presumably were infected by contact with cows that had diarrhea. *Salmonella typhimurium* was isolated from both cattle and men that were ill.

Salmonellae were isolated from shell eggs and frozen egg whites in several epidemics and from packages of a powdered scrambled egg product. Numerous outbreaks were reported following the eating of chicken and turkey meat, especially the latter. In others, food handlers were the probable source of infection. A number of cases of salmonellosis were traced to contaminated well water, seldom reported as a source. The wide distribution of *Salmonella* and the possibilities for spread in a community are indi-

Both authors are with the National Office of Vital Statistics. Dr. Dauer is medical adviser to the chief, and Mr. Davids is health program representative.

cated by a summary prepared by the health department laboratory service of a large western city. Twenty-seven different subtypes of the organism were isolated from 209 persons in 1958. These subgroups included 10 in group B, 11 in group C, 3 in group D, 2 in group E, and 1 in group G. Seventy-two strains of *S. typhimurium* were isolated, 23 of *Salmonella saint-paul*, 16 of *Salmonella oranienburg*, 14 of *Salmonella newport*, 13 of *Salmonella montevideo*, 11 of *Salmonella infantis*, and 10 of *Salmonella give*. The same variety of types has been reported where laboratory diagnostic services are extensively utilized.

Since only a fraction of the outbreaks caused by staphylococci and salmonellae and by other organisms appear to be reported, the real extent of the foodborne diseases is unknown. Year after year the same few States report the majority of the outbreaks summarized in these annual reports. Other States report a moderate number, and some report none. The reports from certain large cities are conspicuous by their absence. More complete reporting is needed not only for measuring the magnitude of the problem but also to show what is needed for improvement in food handling facilities and practices and for planning more effective control programs. Furthermore, the food industry is fourth largest of all industries in the United States, and the quality of its products is the direct concern of all persons.

The various categories of foodborne and waterborne disease outbreaks reported in 1958 are discussed and tabulated in the same manner as in the report for 1957.

Waterborne Outbreaks

Only four outbreaks were demonstrated to be due to contaminated water. An outbreak of shigellosis followed failure to chlorinate the public water supply of a small city for several days while the water inspector was out of town because of illness in his family. Another outbreak of shigellosis occurred in a group of campers who drank inadequately treated water from a livestock watering tank. The other two outbreaks included salmonellosis resulting from the use of a polluted well and gastroenteritis due to contamination of a public water supply,

although the manner in which the supply was contaminated was not determined.

Milkborne Outbreaks

Milk and milk products were considered the source of infection for 13 outbreaks. Cheese and cheese spreads were implicated in five outbreaks, several of which occurred only among members of individual families. The outbreaks involving Cheddar cheese have been described.

Thirty cases of salmonellosis were traced to raw milk from a certified dairy. In this episode a bottle washer continued to work at his job while he was ill. About a week after the onset of his illness, a stool specimen was found to be positive for *S. dublin*. In another State,

five cases of salmonellosis were thought to be due to milk from a small uninspected dairy. An outbreak of salmonellosis in a hospital was traced to malted milk, but raw eggs used in the preparation of the milk drinks may have been the primary source of infection. Another outbreak in a hospital, not included in the milkborne category, was thought to be due to eggs used in making eggnog. Investigation revealed the flock which supplied the eggs was infected.

Reconstituted dried, nonfat milk was the source of infection for 15 cases of gastroenteritis in a labor camp. Not included in the milkborne category was an outbreak of 75 to 80 cases of gastroenteritis, thought to be due to milk served from dispensers in a university dining room. But this could not be proved, and milk

obtained several days later from the dispensers did not show evidence of contamination.

Typhoid Fever

Only one outbreak of typhoid fever was reported during 1958 in which food or drinking water was incriminated. The organisms recovered from the ill persons were phage type E₁. However, several other episodes of typhoid fever were reported. Three boys became ill with typhoid fever after swimming in a stream which carried untreated sewage. The organism in this instance was also phage type E₁. In another instance, six cases with one death occurred over several weeks in a slum community which did not have public water and sewerage facilities.

Salmonellosis

Twenty-seven outbreaks of salmonellosis were reported in which laboratory confirmation was made either by isolation of organisms from the food, from the stools of the ill persons, or from food handlers. Four of the outbreaks were related to ingestion of chicken meat and four to turkey meat. The source of the food for 10 of the outbreaks was public eating establishments. Eleven species of *Salmonella* organisms were isolated. Among these were *S. typhimurium* in seven instances and *S. dublin*, *Salmonella sandiego*, and *S. saint-paul* in two outbreaks each.

Several other outbreaks were reported, but no foods were thought to be involved. *Salmonella reading* was isolated from a package of powdered egg product which was served at a Boy Scout ranch, but no cases resulted.

Shigellosis

Three outbreaks of shigellosis were reported. Two resulted from contaminated water supplies and the other from a tossed salad. The responsible organism in each instance was *Shigella sonnei*.

Shigella flexneri 2a was found to be responsible for a number of cases of shigellosis which occurred over a 2-week period in an unsanitary labor camp. And *S. flexneri* 4 was responsible

for an outbreak in a boarding home for children, but no common source of infection was found in either episode.

Trichinosis

In two of the seven outbreaks of trichinosis reported during 1958, the source of infection was homemade pork sausage. In another, it was pork sausage prepared by a local butcher. In a fourth outbreak, dietary histories indicated that ham had been eaten. Investigation revealed that the ham itself probably was free of viable *Trichinella* and that contamination could have taken place by the addition of raw pork. In this outbreak 78 persons developed symptoms of trichinosis, and about 45 of these gave definite laboratory evidence of recent infection.

Botulism

Four cases of botulism were reported. Two persons became ill after eating home-canned string beans which had been discarded by another family because they looked spoiled. The beans were heated in a skillet before serving. *Clostridium botulinum* was identified morphologically and culturally from the original jar of beans. One other case resulted from eating home-canned mushrooms, and no particular food was incriminated in the illness of the fourth person.

Staphylococcal Food Poisoning

Most of the 62 outbreaks of staphylococcal food poisoning occurred following meals in public eating establishments and private homes. The foods most often involved were meats other than poultry. Eclairs and custard-filled desserts were proved by laboratory tests to be the vehicle of infection in only six outbreaks.

Gastroenteritis, Etiology Unknown

More than one-half of the total waterborne and foodborne outbreaks were of unknown etiology. Poultry and other meats were the suspected vehicles in 72 of them. The two most frequent sources of infected foods were public

eating establishments and private homes. Usually food samples were not available for laboratory examination, and, when specimens were obtained either from the food or from the ill persons, the results were negative or inconclusive for food-poisoning organisms.

Chemical Poisoning and Noxious Foods

Five reports of chemical or noxious food poisoning, each affecting only a few persons, were related to the ingestion of wild mushrooms. Another report stated that 20 children became ill when a dining room was sprayed with an insecticide while the group was eating. Several other outbreaks of chemical poisoning

resulted from contamination of punch drinks with metals from the containers in which the drinks were stored. Zinc, antimony, and copper were the metals involved.

In two instances beef and French doughnuts were found to be contaminated, and in another instance a number of persons became acutely ill while eating soup in a restaurant. Investigators thought the illness was due to chemical poisoning, although there was no definite evidence of such contamination. One case of lead poisoning resulted from ice used in alcoholic drinks. The ice was stored in a chest which had a lead slab lining the bottom, and chips of the lead were scooped up along with the ice.

Drugs and the Newborn

Newborn mammals lack the ability to alter drugs into inactive products, investigations at the National Heart Institute, Public Health Service, indicate.

Dr. Bernard B. Brodie, Dr. W. Robert Jondorf, and Dr. Roger P. Maickel of the Institute's Laboratory of Chemical Pharmacology found that the enzymes located in the liver microsomes which are required to inactivate drugs are absent in newborn mammals during the first week of life. They also found that the central nervous system of the newborn is extraordinarily sensitive to barbiturates.

The researchers compared the ability of mice and guinea pigs of various ages to metabolize several commonly used drugs. Guinea pig livers were homogenized and incubated with various test drugs, including aminopyrine, phenacetin, hexobarbital, phenolphthalein, and monomethyl-4-aminoantipyrine. The experiments showed that the drug-destroy-

ing enzyme systems are absent in fetal and newborn guinea pigs, but appear during the first week of life and require about 8 weeks to develop fully. The liver incubation studies were confirmed by demonstrations that live, newborn mice are unable to metabolize aminopyrine, phenacetin, or hexobarbital.

An additional potential danger of giving drugs to the newborn was observed in studies of hexobarbital action. Very small doses (10 mg./kg.) put 1-day-old mice to sleep for 360 minutes, and 7-day-old mice for 107 minutes. Adult mice napped for less than 5 minutes under the drug's influence.

"That newborn mammals are unable to metabolize these compounds is of obvious importance in considering the use of drugs in childbirth and for newborn infants," the scientists said. They also stressed the importance of making detailed studies of drug action in newborn infants.

Health Insurance and Hospital Use Related to Marital Status

AGNES W. BREWSTER and LUCY M. KRAMER

THERE threads through the work of the Social Security Administration a concern with the family status of the persons whose lives its programs may affect. In that respect it is unlike many agencies of government whose relations to people are more remote and impersonal.

Social security benefits are payable not only to insured retired workers but also to their wives and to widows and surviving children of insured persons as well. Old age assistance caseloads contain large numbers of widows and widowers. Aid to dependent children is frequently needed because the absence of a parent has disrupted the family. In its studies of various income maintenance programs for which it is responsible, the Social Security Administration is constantly examining family status. Similarly, questions of levels of expenditures need to be related to family status since expenditures have significance according to the number of persons the family income must support.

Expenditures for sickness and for the maintenance of health, like other consumer expenditures such as food and clothing, are influenced by family size and family income. To some degree the medical expenditures may be gov-

erned by selections the family can make, such as postponement of care, or care at home in lieu of hospitalization. However, other medical care expenditures, such as those for maternity, generally are consequent to the establishment of a family, and the choice as to avoidance or postponement is limited.

British (1,2) and Canadian (3,4) studies have demonstrated differential use of hospitals as between single and married persons, with single persons making greater use of hospitals.

According to the recent study of Britain's National Health Service by Abel-Smith and Titmuss, "Compared with the demands made by single men and women (and, to a lesser extent, the widowed) the proportion of married men and women in hospital even at age 65 and over is extremely small. . . . For all types of hospital and in relation to their numbers in the total adult population, the single, widowed, and divorced make about double the demand on hospital accommodation compared with married people. . . . Marriage and its survival into old age appears to be a powerful safeguard against admission to hospitals in general and to mental and 'chronic' hospitals in particular" (1a).

Table 1 summarizes the result of a one-time hospital population count made in England and Wales as part of the regular British decennial census. Abel-Smith and Titmuss drew three major conclusions from this table: (a) among both sexes with advancing age the proportion in hospitals in England and Wales at the time of the census rose most sharply for the single, less so for the widowed and divorced, and least for the married; (b) among

Mrs. Brewster is a medical economist with the Social Security Administration in the Office of the Commissioner. Miss Kramer is a research analyst with the Division of Public Health Methods, Public Health Service. This article is based on five Research and Statistics Notes (Nos. 13, 14, 17, 19, and 25) by Mrs. Brewster, issued in 1958 by the Division of Program Research, Social Security Administration.

Table 1. Percentage of 1951 census population in all National Health Service hospitals in England and Wales by age, sex, and marital status

the married, even at age 75 and over, the proportion in hospitals was 2 percent or less of the population; (c) at all ages the proportion of men, single, widowed, and divorced, in hospitals was higher and rose more sharply than the corresponding rates for women (1b).

Table 2 shows the average days of stay in Saskatchewan, Canada, hospitals in 1957 by age, sex, and marital status. In every age and sex category but one, the average length of stay is less for married persons than for single, widowed, divorced, or separated persons. In the one excepted category, men 45 years and over, the length of stay is the same for married as for widowed, divorced, or separated men, but both are less than the stay for single males.

These findings are of interest to those sectors of the Federal Government concerned with factors in the cost of sickness and the price of health. In the experience of Great Britain and Canada, two countries with a national health insurance program, the economic cost to an individual family is not a factor in hospital utilization. It is apparent, then, that factors other than income are in part responsible for differences in levels of hospital usage. For example, living arrangements, levels of health, ownership of health insurance, and similar conditions, some of which are related

to income and to marital status, also affect the amount of hospital care used.

The regular monthly Current Population Survey of the Bureau of the Census in September 1956 had a supplement on insurance coverage and hospital utilization. This afforded an opportunity to explore some facets of the use of hospitals in the United States by married and nonmarried (single, divorced, or widowed) persons. The household sample, on a national scale, was drawn from the civilian noninstitutional population living within the continental United States. About 27,000 households comprising approximately 90,000 persons were included. Excluded were members of the armed services, inmates of mental or penal institutions, and residents of homes for the aged, infirm, and needy. The findings which resulted are the subject of this study.

Before analyzing hospital utilization by the married and nonmarried in terms of various other factors, it is necessary to examine the extent to which health insurance protection is available to the married and the nonmarried sectors of the population. Under our system of voluntary health insurance, availability of health insurance to many women may be dependent on their status as a spouse.

HEALTH INSURANCE OWNERSHIP

Differences in the number of noninstitutionalized persons having health insurance in any given population group are to be expected, given the variety of conditions and techniques for enrollment of members and their dependents. Differences in the extent of group coverage relate to the degree of urbanization and industrialization of a community, and hence to the availability and cost of group policies. Age, income, and similar factors affect the proportions of the population insured under nongroup arrangements.

Extent of Ownership

Table 3 indicates that there is little difference based on sex in the extent of enrollment per 1,000 in the group under age 65, and in the whole population group. The census findings for September 1956 show improvement since the earlier

Table 2. Average days of stay per year in Saskatchewan, Canada, hospitals by age, sex, and marital status, 1957

surveys of 1952 and 1953 in the relative position with respect to health insurance ownership of aged women compared with aged men.

Surveys made in 1952 and 1953 of persons with insurance by various characteristics provide comparative data for measuring the differential rates of growth in coverage. The March 1952 survey was made by the Bureau of the

Census for the Division of Program Research, Social Security Administration, and encompassed the population aged 65 and over (5). The July 1953 survey covered the population of all ages and was made for the Health Information Foundation by the National Opinion Research Center (6).

Aged women, particularly those who are not married, are relatively poorly covered according to the September 1956 findings. Although in the corresponding group of aged unmarried men the rate per 1,000 is even lower, married men aged 14-64 achieved the largest degree of health insurance coverage of any of the segments into which the September 1956 population has been divided. (The segments are age, sex, race, labor force status, marital status, and income levels.) The rate for this group, married men aged 14-64, was above the rate per 1,000 for the white population per se and for the entire working force population. In the 14-64 age group there were 25 more insured persons per 1,000 recorded among married men than among married women. The rate is particularly noteworthy since the analysis of hospital utilization by different population groups,

SOURCE: Bureau of the Census Current Population Survey, September 1956.

which will be discussed later, shows that this high rate of insurance coverage applies to a group whose need of hospitalization appears to be below average as indicated by the volume of hospital care used.

Table 3 also shows marked differences in rates of health insurance ownership when the white population is compared with the non-white population, especially when persons over age 65 are compared. Thus, while 670 white persons per 1,000 of all ages were insured, only 353 nonwhite persons per 1,000 were insured. And in contrast to 379 white insured persons aged 65 and over, only 173 nonwhite persons in this age bracket were insured per 1,000.

Participation in the labor force is also linked to health insurance ownership, with more significant differences among men than women. In the age group 14-64, 691 men per 1,000 in the labor force were insured compared with 543

per 1,000 not in the labor force. Among women in the same age group, the numbers insured were 689 per 1,000 in the labor force and 654 per 1,000 not in the labor force. The closeness of these two figures results from the fact that many women not in the labor force are covered through their husbands' employment. This is demonstrated by the fact that, of the women in the age bracket 14-64 who were married, 698 per 1,000 were insured, compared with 597 per 1,000 insured who were not married.

In general then, of the total of 636 persons per 1,000 in the population of all ages who owned health insurance in September 1956 (table 3), there were larger numbers among the white race, among those in the labor force, and among the married than among the non-white, the nonworker, and the nonmarried. The group with the greatest health insurance coverage, 723 per 1,000, were married men aged

Nonwhite-----	0.2	1.4

Table 4 presents the proportions in each age-sex group who were insured in September 1956 for hospitalization alone and for hospitalization and additional benefits. The group insured for hospitalization and additional benefits is subdivided into those reporting surgical expense insurance (possibly also with some protection against nonsurgical medical expenses in the hospital) and "other," those whose insurance appeared to the interviewer to include more benefits than the local Blue Cross-Blue Shield plan or the typical insurance company policy. Persons whose protection was through accident-only policies, travel-accident policies, or medical expense insurance under automobile liability policies were not counted as insured. Persons in the category labeled "other" in table 4 are all assumed to be insured against the costs of hospital care as well as against surgical and medical expenses. The table shows that 55 percent of the population had insurance covering other benefits as well as hospitalization, 8 percent had insurance limited to hospitalization, and about 36 percent had no insurance of any kind at the time of the interview.

As of the September 1956 survey, nearly two-

thirds of those in the age groups under 65 had insurance, but only 36 percent of the population aged 65 and over were insured. Of the insured aged, roughly one in four had only hospitalization insurance, whereas among insured persons under 65 only one in eight had benefits limited to hospitalization.

In the remainder of this study, persons are considered insured or not insured without further delineation of the scope of their benefits. The proportion of those insured in any age group who had only hospitalization insurance should be kept in mind. Those ratios by age groups are:

Percent of insured with

hospitalization only

Age group (years)

survey (table 5). In census terminology, persons living in a family headed by a person related to them by blood, marriage, or adoption are members of "primary family units." The income shown for the family unit in which the aged person lives is not necessarily that of the aged person but would include his income. In the household interviews information was also obtained on the annual income of individuals not living with any relatives, "primary individuals."

Comparatively few aged persons living in families with low incomes were found to be insured. Only 174 per 1,000 aged persons in families whose incomes were under \$1,000 reported having health insurance. When family income was \$5,000 or more, 477 per 1,000 aged were insured.

Although family income was not necessarily

the income of the aged person, the family income in many instances was that of an aged couple. However, the fact that the proportion of women insured was not highest in the \$5,000 and over class may reflect the relatively large number of aged women who live in the households of relatives other than their spouse.

Table 5 also shows the proportion insured when the income reported was that of aged persons classed as "primary individuals." No one in these households was related to the head, so the income shown in all instances is that of the aged person. Among individuals with less than \$1,000 in annual income, about one in five was insured. When their income exceeded \$3,000 annually, more than half of the aged individuals reported owning health insurance.

Insured aged persons were fairly evenly distributed at each level of family or individual in-

The size of the sample of aged persons precluded further cross classification. It would have been informative, for example, to cross classify insurance and annual income level with labor force participation, with age, and with marital status.

Table 6 enables one to see simultaneously several of the characteristics of insured and uninsured persons in the population aged 65 and over. Half of the insured aged are in the age bracket 65-69. (Twenty-five percent of the aged are both 75 and over in age and have no insurance. Twenty-four percent of the aged population consists of nonmarried uninsured women; nearly half of this group has passed the 75th birthday.)

A third of the insured aged population was still in the labor force, although among aged persons as a group, only one in four was in the labor force.

The population "14 and over" is usually selected by the Bureau of the Census for studies of labor force participation, marital status, and

the like, subdivisions of significance also in relation to health insurance ownership. In the population as a whole in the September 1956 survey, about 30 percent were under age 14 and, like the adults or the population of all ages, two-thirds of the children were insured. Table 7 shows how the insured portion, two-thirds of the whole, differed from the uninsured portion of the population aged 14 and over. The relative numbers who were married, the degree of participation in the labor force, and the proportions who were aged 65 and over were quite different in the insured and uninsured segments of the population. The group not reached to date by insurance presents special problems of enrollment.

Recent Growth in Coverage

Data collected in interviews in sample households generally have yielded lower rates of insurance protection for the public than those for recent years published by the Health Insurance Council, whose member companies account for more than 90 percent of the health insurance issued by the insurance business (7).

Measurement of Growth

Sampling errors are possible in studies based on interviews, and underenumeration may

have occurred for several reasons. The sample households do not include the institutional population, some of whom have health insurance. The person being interviewed may not be cognizant of the family protection available through the employment of the head of the household. However, in the September 1956 survey the families being interviewed were asked in advance to check on their health insurance so that they could be responsive to the interviewer's questions. Finally, persons protected by more than one policy are of course counted only once as insured, regardless of the number of policies they may have covering the same type of medical expense. It is also possible that some overstatement results from interviewing persons who are unfamiliar with the provisions of their policies and who may confuse accident-only policies, travel-accident policies, and automobile policies which include medical benefits with the kinds of health and medical care insurance the surveys attempt to measure.

There is also some justification for the belief that national aggregates may contain some overstatement. National aggregates, obtained company by company from health insurance underwriters, require correction for duplicate coverage; this correction is made on the basis of periodic sampling. As more and more em-

ployers include health insurance as a fringe benefit, the likelihood of husbands and wives each having family coverage when both are working is increased. A second area of uncertainty arises in connection with dependent coverage, since many carriers do not know how many children are included in family policies. A third area of uncertainty results from fluctuations in employment in a given occupation, which may change the number of persons entitled to benefits at a given moment.

Finally, the tendency to report coverage in round numbers may also exaggerate the actual count. In its studies of self-insured union plans, the Division of Program Research, Social Security Administration, has noted that the reports received frequently state coverage in such round terms as "5,000 members and 14,000 dependents," whereas an actual count might yield a considerably lower figure (8).

Comparative Data on Coverage

In 1953 the household survey made by the National Opinion Research Center showed 570 persons with hospital insurance per 1,000 population. The Health Insurance Council data yielded a mid-1953 figure of 611 persons per 1,000, 41 more persons per 1,000. For 1956 the Current Population Survey of the Bureau of the Census indicated 636 persons per 1,000 as having hospital insurance; the council's figure was 682, or 46 more persons per 1,000. However, growth between the two sample survey periods was 66 per 1,000 and growth recorded by the Health Insurance Council in the same span of years was 71 per 1,000. These are closely corresponding figures.

Table 8 presents data for the years 1948-57 from the Health Insurance Council for the number of persons estimated to have hospital, surgical, and medical expense insurance as of December 31 in each of the 10 years. Three hundred more persons per 1,000 had hospitalization insurance at the end of 1957 than at the end of 1948, in a period when population rose 23.2 million. Surgical protection rose even more rapidly. The number with any form of medical expense insurance increased from less than 1 in 10 to more than 4 in 10.

These national aggregates do not afford any measure of the characteristics of the popula-

tion that is being increasingly included under various health insurance plans. Such information can only be obtained from household interview survey data of the kind given in tables 6 and 7. Tables 9 and 10 show the extent of growth in enrollment recorded by age and sex between the September 1956 survey and two earlier surveys.

Between July 1953 and September 1956, the number of insured persons per 1,000 in the population showed an increase of 66 (table 9). Averaged over the 3-plus years, this is an increase of about 22 persons per 1,000 per year. (In this period the population increased by 10 million, an increase that decidedly offset the gross expansion in the number of persons with insurance. The population aged 65 and over increased by about a million in the same period.) The largest relative increase in any age group was registered among women aged 65

and over in which 75 additional persons per 1,000 raised the proportion insured from 267 per 1,000 to 342. The smallest increase was among men in this same age bracket, 36 per 1,000. In the other age groupings, the number of insured men per 1,000 added in the interim was larger than the number of additional insured women per 1,000.

With the spread of family coverage in the last few years, it would be expected that females under age 65, who were found to have a larger number insured per 1,000 than males in the earlier surveys, would have maintained or added to their lead. By the September 1956 survey, however, younger women were found to lag behind men in the proportions insured. The differential between men and women was reduced, however, between the two survey dates for those aged 65 and over.

The National Opinion Research Center sample was relatively small at the higher ages, reducing the possible significance of the 3-year comparison for this age bracket. However, rates for the aged found in the March 1952 Current Population Survey, when compared with those of the September 1956 survey, con-

firm the improvement in coverage of aged women in recent years (table 10). Identical survey techniques were used in the two surveys.

The largest gains in insured persons, 146 per 1,000, have been achieved among women aged 65-69. This finding provides strong evidence that many persons who were in the age bracket 60-64 in 1952 and now would be in the age bracket 65-69 have maintained the insurance coverage they had before they reached their 65th birthday. As further evidence that older people are continuing their insurance, the proportions with insurance that were found for those aged 65-69 in March 1952 are comparable to those for the age bracket 70-74 in 1956.

Since no survey prior to the September 1956 study examined the marital status of the insured population, no conclusions can be drawn from tables 9 and 10 as to relative improvement in coverage in this respect.

HOSPITAL UTILIZATION

Before examining the relation of hospital utilization to marital status, a review of the reasons why people of different ages are admitted to hospitals would be helpful.

Why People Enter Hospitals

In their analyses of data from the 1956 survey, Odoroff and Abbe (9) showed that for the population of all ages (both sexes combined) approximately a fourth of all admissions were for surgery, more than a fifth were for obstetrics, nearly a third were for other causes, and only 6 out of 100 admissions were for accidents. In their analysis, pediatric admissions were separated from the other categories and accounted for 16 percent of all admissions. Their report shows the average stay for surgical procedures as 10.6 days, with accidents averaging 12.1 days, obstetrics, 4.5 days, pediatrics, 5.2 days, and other reasons, 9.3 days.

The annual rates of persons hospitalized are lower than annual admission rates since some of the persons hospitalized have more than one period as a patient. In the total survey population there were 1,174 admissions for each 1,000 persons hospitalized. In the population 14 and

over, insured hospitalized persons had fewer admissions than uninsured hospitalized persons, and admissions among males, particularly uninsured males, exceeded those among females per hospitalized person. Multiple admissions increased with age.

However, for present purposes, admission rates rather than rates of persons hospitalized are more meaningful, since the reason for being admitted has significance only in relation to each separate hospital stay.

The data on hospital utilization, admissions and length of stay based on household interviews, did not include persons who did not survive the year prior to the survey date. As a result, the rates underestimate the actual use of hospitals by a given population, probably by about 25 percent for the aged and somewhat less for all ages.

Table 11 divides hospital admission rates per 1,000 among four broad categories given by respondents in the household interviews as reasons for having been in the hospital. Four significant facts are discernible from the rates as tabulated: (a) insured persons are admitted with greater frequency than uninsured persons for operations and for all conditions other than

accidents, and this holds regardless of age or sex; (b) the admission rate for accidents and injuries is identical for each of the two age groups of males aged 14 and over and 14-64, with almost no differences in the rates for insured and uninsured; (c) the admission rate for accidents and injuries among females in the age bracket 14-64 is less than half that of males of the same ages, while the admission rate for accidents among insured females 65 and over is twice that for uninsured aged females or for insured aged males; and (d) in the age group 14-64, more insured than uninsured women per 1,000 were admitted for childbirth. (Although one in two admissions was for childbirth among uninsured women, only about one in three admissions among insured women was for this reason.)

Under age 14 and after age 64 males have more admissions for operations per 1,000 than females. In fact the rate of admissions for operations among elderly males with insurance, 58 per 1,000, is nearly double that of younger insured males. In contrast, among the older men the proportion of admissions for accidents or for other reasons was about the same whether or not there was insurance. This similarity in reasons for admission was not found among

older women; the insured older women had a greater volume of admissions for each cause of admission than the uninsured.

Relation of Marital Status to Use

Table 12 shows by sex the annual admissions, days of stay per admission, and days per 1,000 used by married or nonmarried (single, divorced, or widowed) persons. The insured and uninsured are contrasted by marital status.

Annual Admission Rates

In the analysis of admissions per 1,000, some interesting if not altogether unexpected relationships emerge. Among males aged 14 and over, or aged 14-64, the married men have a higher admission rate than the nonmarried men. The average age of the married men may be higher than that of the nonmarried group of males, and therefore differences in health that come with age may account for at least part of the difference in admission rates. This seems to be the case among insured males in this age bracket, for the average hospital stay of those who were married was 1.1 days longer than among those who were not married. This does not serve to explain the very low admission rate coupled with a relatively long stay found among uninsured nonmarried males. Seemingly this group entered the hospital only when so seriously ill that a prolonged stay was often necessary. Also it may reflect the absence of a wife concerned with the health of her spouse and alert to a condition that needed immediate hospital care.

Mortality data by marital status in the continental United States for 1957, collected by the National Office of Vital Statistics, Public Health Service, are available for the first time since 1953 (table 13). A comparison of the 2 years shows that death rates by marital status have remained about the same, and that "in each age group, for both sexes, the death rate for unmarried persons is higher than for married persons. . . . For both the married and the unmarried, the age-specific death rates for males are higher than the corresponding rates for females" (10a).

It would appear that with or without health insurance or hospital utilization, marital status

is related to health, as the Abel-Smith and Titmuss study concluded (1), and that single non-married males have a less favorable health outlook.

In the male group 65 and over, in which the average age of married and nonmarried men is undoubtedly more similar, single men have higher hospital admission rates, and the difference between the married and nonmarried group increases with advancing age (table 12). The absence of a spouse probably made use of the hospital unavoidable in some instances. These differences are found whether or not the patient has insurance, although two exceptions occur: the insured married men aged 65-69 and 70-74 in the sample have a higher admission rate than the corresponding nonmarried men but do not remain so long in the hospital. For the 70-74 group in particular, the figures may well be due to sampling error.

Like the men, married women aged 14 and over use hospitals more often than single women, even when childbirth is excluded. Married insured women aged 14-64 used hospitals at a very high rate since more than one

in five was admitted in the course of the 12 months. Even though 68 of the 214 admissions per 1,000 recorded for these women were for childbirth, there still remained 146 admissions per 1,000 for other causes, nearly double the rate of 75 for the unmarried insured women.

All the admission rates of aged uninsured women are much lower than the rates of the corresponding groups of aged uninsured men.

Like the men, at the older ages insured women who are not married enter hospitals with greater frequency than insured married women. Single insured women make more use of hospitals than any other group. In addition, unlike the older men, uninsured older women who are not married are somewhat less likely to be admitted to hospitals than uninsured married women. Since aged widows are found in great numbers in this age group, there appears to be a relationship between low income, no insurance protection, and lack of hospital care.

The presence or absence of insurance appears to have a differential effect on hospital admissions depending on sex and age. Among males aged 14-64, the fact that they are married increases admission to hospitals to about the same extent as the fact that they have insurance protection. Among the women in this age bracket, even after excluding admissions for childbirth, the fact that they are married appears to increase admissions decidedly. The presence of insurance further increases the non-obstetrical admissions of married women, while the presence or absence of insurance has little effect on the proportion of nonmarried women admitted to hospitals. Being married increases admissions from 50 percent (among the uninsured) to 100 percent (among the insured) over their nonmarried counterparts. Married insured women enter hospitals 2.3 times as often as single uninsured women.

After age 65, insurance ownership increases admissions somewhat among married men but has little effect on unmarried men. Among elderly women, the presence of insurance is more important than the presence or absence of a spouse in increasing hospital admissions.

When hospital admissions are broken down into smaller age groups for the total group, the admission rates for both sexes combined are

highest in the childbearing years 25-34 (table 14).

Length of Stay

Admission rates to hospitals reveal only part of the picture, however. With only three exceptions (insured men in the age groups 14-64 and 75 and over and uninsured women in the age group 65-69) the unmarried patients average longer stays in the hospital than the married patients (table 12). Among the male group the uninsured married men in general remain longer on the average than the insured married men; the same is true when the insured and uninsured who are not married are compared. In the latter case, the average stay is considerably longer for the patient group containing the uninsured who are not married. The differences in average length of stay between married or not married and insured or not insured is not nearly so decided nor so consistent among the women.

Length of stay per admission rose consistently with increasing age, except for minor deviations after age 69 where the sample size probably caused some variation. Nevertheless, the average stay for the total hospitalized population did not exceed 20 days in any age group (table 14).

If males and females are compared by age-sex-marital status groupings (table 12), the average for males in some categories after age 65 was higher than 20 days (in the unmarried and, in some cases, the uninsured categories). Stays of all durations from a day or two to practically a full year were included in the survey data.

Annual Rates in Days

Volume of hospital care in annual days used per 1,000 was higher for insured than uninsured in almost every age group (table 14). The insured population as a whole used 83 more days per 1,000 than the uninsured.

The third part of table 12 provides contrasts between married and nonmarried persons in the annual days of hospital care used. Relatively low use of hospital days was recorded for all the categories for the unmarried at the younger ages, and among aged uninsured women, whether or not they were married.

Table 14. Hospital utilization rates by insured status and age group, year ending September 1956

Age group (years)	Annual admissions per 1,000 population			Average days of stay per admission			Annual days per 1,000 population

SOURCE: Same as for table 3.

In sharp contrast either with unmarried women or with married men is the volume of hospital care recorded per 1,000 older unmarried men, whether insured or not. Their rate exceeds even the rate of women in the childbearing years. In fact, more than 6 days annually per capita were used by unmarried uninsured men aged 65-69. In this same age bracket, uninsured married men accounted for less than 2 days per capita, and uninsured unmarried women used only about one-half day per capita in the survey year.

SUMMARY

As of September 1956, the civilian noninstitutional population residing in the continental United States had the following characteristics with respect to marital status, health insurance, and hospital utilization:

About two-thirds of the total population had some form of health insurance protection, one-third had none.

Nearly two-thirds of those under 65 had health insurance in some form; only 36 percent of those over 65 were insured.

Among the aged, the proportion with insurance declined with advancing age, so that fewer than one-fourth were insured among those 75 and over.

Of the insured aged, that is 65 years and over, 1 in 4 had only hospitalization insurance,

whereas among those under 65, only 1 in 8 had benefits limited to hospitalization.

Of the insured population, 95 percent were under 65; 30 percent were under 14. Ninety-four percent were white; 6 percent nonwhite. Of those 14 and over, 63 percent were in the labor force; 88 percent of the insured men and 40 percent of the insured women were working or looking for work. Since approximately equal numbers of married men and married women were insured in the 14-64 age group, it is obvious that many of the women obtained their insurance by virtue of their husband's employment.

Of the uninsured population, 15 percent were aged over 65, 85 percent under 65, and 29 percent under 14. Nineteen percent were nonwhite. Of those over 14, only 51 percent were in the labor force, 73 percent of the men and 32 percent of the women. Four in 10 were not married, and 1 in 10 was both over 65 and not married. Twenty-two percent of the women were 65 and over, most of them neither in the labor force nor married.

The uninsured include large proportions who are not gainfully employed as well as many of the aged who have only small retirement incomes or no incomes. The uninsured, therefore, appear to be difficult to enroll under any of the usual methods of group enrollment used by insurance companies and plans.

The aged insured were heavily concentrated

in the age bracket 65-69. Although only 38 percent of the aged population fell in this age group, half of the insured aged population was found in it, and less than a third of the uninsured aged population.

The aged insured population was almost entirely white; only 3 percent were nonwhite. Nine percent of the uninsured aged population was nonwhite.

The findings from the September 1956 survey and the comparison with the March 1952 survey point to the conclusion that persons entering the retirement years continue the health insurance they obtained when they were younger if it is possible to do so. A fairly high level of insurance protection exists among persons in the labor force and among married persons. Lacking such protection are those with low incomes and those who are neither in the labor force nor married to a person who is or has recently been in the labor force.

Among the insured, hospital admissions were more frequent than for the uninsured but the stay was shorter. Average stay for the insured was 7.4 days; for the uninsured, 10.3 days. Average stay for both groups combined was 8 days. Insured persons used 83 more days of hospital care per 1,000 than uninsured persons in the course of a year.

Admission rates were highest at age 25-34 for the total group; admissions for maternity during the childbearing years affected the rate for both sexes combined.

Length of stay per admission rose with increasing age. The average stay per admission never exceeded 20 days in any age group.

The volume of hospital care, that is, the annual rate per 1,000, was higher for older unmarried men, whether insured or not, than for married men or unmarried women. It exceeded even the rate of women in childbearing years.

Between the ages of 14 and 64 marriage appeared to be a factor associated with greater use of days of hospital care, whereas insurance ownership had no appreciable effect, except among married women. After age 64, the greatest impact on days of hospital care among

the men appeared to be related to their wifelessness and not to their having or not having insurance. Among aged women both marital status and insurance had an impact; single insured women were the largest users of days of hospital care; single uninsured women were also generally the smallest users, particularly in the 65-69 age group.

Observations on Asian Influenza on Two Alaskan Islands

ROBERT N. PHILIP, M.D., WILLARD T. WEEKS, M.D., KARL R. REINHARD, Ph.D.,
DAVID B. LACKMAN, Ph.D., and CAROLYN FRENCH, R.N.

IN OCTOBER 1957, the variant of type A influenza virus commonly referred to as Asian virus was widely prevalent in larger urban centers and many native villages of Alaska. A second wave of influenza was noted early in 1958 in a few villages in southern Alaska which had previously escaped the disease. The overall influenza morbidity in the State is not precisely known but undoubtedly was high. The general mildness of the disease was reflected in influenza and pneumonia mortality rates. They were only slightly higher during October than normally expected for that month, according to the Alaska Department of Health.

Influenza likewise occurred in several remote island communities of Alaska, two of which were St. Paul, Pribilof Islands, and Gambell, St. Lawrence Island, where opportunity was afforded for rather complete investigation. Results of the investigation reported here are of interest because the communities were more isolated than those populations from which most information on Asian influenza has been derived. This isolation facilitated tracing the

mode of introduction of disease into each village. Attack rates were extremely high, and the frequency of pulmonary complications in St. Paul was higher than observed generally.

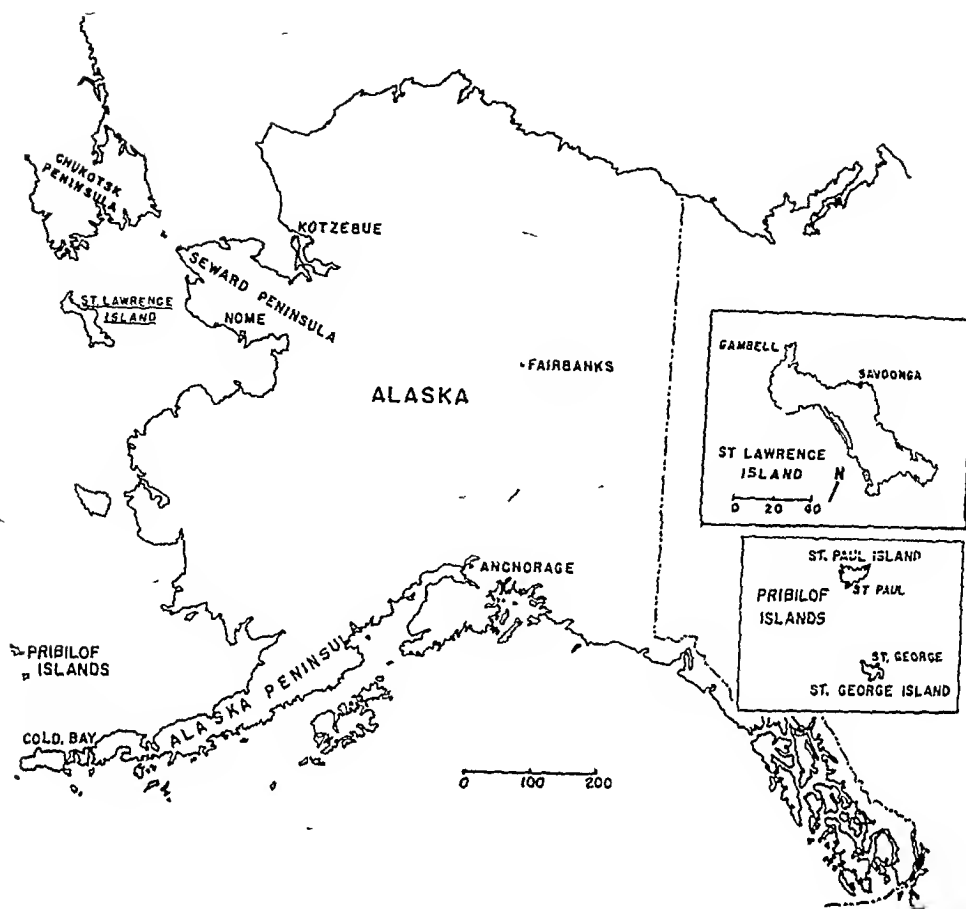

Background

St. Paul Island is in the Bering Sea approximately 250 miles northwest of the Aleutian chain (fig. 1). The chief mode of travel to St. Paul is by weekly commercial air service from Cold Bay on the Alaska Peninsula. Travel by boat is limited to infrequent visits by U.S. Fish and Wildlife Service and Coast Guard vessels. The neighboring island community of St. George is only 50 miles from St. Paul, but there was no traffic between them during the outbreak in St. Paul. Consequently, influenza did not occur in St. George.

St. Paul village is comprised of some 350 residents most of whom are predominantly of Aleut descent. The chief industry is fur sealing under U.S. Fish and Wildlife Service jurisdiction, and the majority of the few non-native residents are employees of this agency. The village is compact. The dwellings are generally multiroom and clean, have most of the modern conveniences, and reflect the prosperity of the community. Village ties within racial groups are close, and there is much social interchange among households (defined as one or more persons living as a family group under a single roof). Community life centers around the school, church, movie theater, store, and commissary. The residents are well nourished and warmly clothed. Their health needs

Dr. Philip and Dr. Reinhard are with the Arctic Health Research Center, Public Health Service, Anchorage, Alaska. Dr. Lackman serves with the Service's Rocky Mountain Laboratory, Hamilton, Mont., and Mrs. French is the Alaska Department of Health nurse on St. Lawrence Island. At the time this study was prepared, Dr. Weeks was the Public Health Service medical officer stationed at St. Paul, Pribilof Islands. (Manuscript received for publication March 4, 1959.)

Figure 1. The State of Alaska, with St. Lawrence, St. Paul, and St. George Islands.

are served by a Public Health Service physician in a small clinic-hospital.

St. Lawrence Island is in the northern part of the Bering Sea approximately 120 miles from Alaska and 40 miles from Siberia (fig. 1). It is inhabited by some 550 Eskimos residing in two communities of similar size, Gambell and Savoonga. At the time of the outbreak, all transportation to the island was by biweekly commercial air service from Nome, Alaska, to Gambell, and all persons traveling to Savoonga pass through Gambell. The Eskimo residents are gregarious, and their villages are usually composed of single-room frame houses which are crowded and poorly constructed in comparison with housing in St. Paul. Community life centers around the school, mission, native store, and National Guard armory. Health services for the island are administered directly by an Alaska Department of Health nurse who

resides in Gambell. Illnesses requiring hospitalization are referred to the Public Health Service's Alaska Native Hospital, Kotzebue.

Influenza occurred in Savoonga also shortly after it was introduced into Gambell. However, details of the outbreak in Savoonga were not sufficiently complete to merit inclusion in this report.

Methods

Clinical observations were based on 192 patients (65 percent of the total 294 cases) who were seen at the clinic during the outbreak in St. Paul. Detailed clinical observations were not obtained in Gambell. Epidemiological observations were obtained in St. Paul by a survey of all households immediately after the epidemic, and in Gambell, primarily from health department nursing records and a can-

vass of all households 1 and 3 months after the outbreak. The majority of illnesses were attended by the nurse who recorded dates and major symptoms. Dates of occurrence of unattended illnesses were obtained in retrospect by relating them to onsets of attended illnesses among household associates.

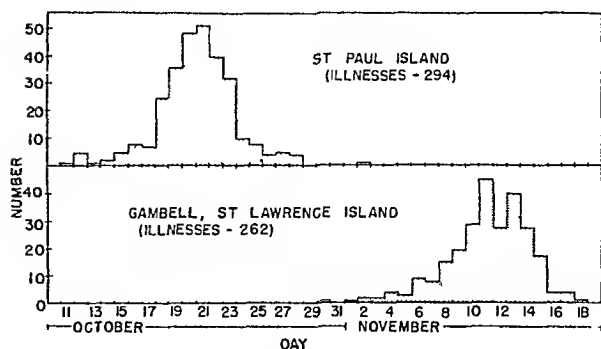

Serologic observations in St. Paul were based on blood serums obtained from 152 persons by Dr. C. M. Eklund, Rocky Mountain Laboratory, Hamilton, Mont., during his investigation of an outbreak of poliomyelitis in 1954 (1), and serums obtained by Weeks from 30 persons 1 to 2 months after the outbreak. Although postepidemic serums in St. Paul were obtained from few persons, most of whom were adults, and donors were not selected on the basis of occurrence of illness during the outbreak, it is felt that the test results are probably representative of adult age groups.

Gambell observations were based on serums obtained from 85 persons during investigation of a mumps epidemic 3 months prior to the influenza outbreak (2) and from 125 persons 3 months after the outbreak. Persons contributing blood specimens prior to the outbreaks were selected only on the basis of availability, cooperativeness, and age. Proportionately fewer serums were obtained from children under 6 years of age than other age groups. Postepidemic serums in Gambell were obtained from all available persons, approximately 6 years or older, who were willing to contribute blood specimens.

Testing was carried out by the hemagglutination inhibition (HI) technique in the manner recommended by Jensen (3) with his suggested modifications (4). Potassium periodate was used to inactivate nonspecific inhibitors to influenza viruses in the serums. Antibody titers are recorded as the final serum dilutions giving inhibitions. Although serums obtained prior to and after the outbreak in each village were not tested simultaneously, human serums of known titers to each test antigen were included as controls in each test.

The influenza virus strains used as HI test antigens included swine (Shope), A/PR8, A/1520 (a Denver-like A' strain isolated in Hamilton, Mont., March 1956), and A/Jap/305/57 (Asian). Antigens were prepared by

Figure 2. Number of illnesses occurring daily during the St. Paul and Gambell influenza outbreaks, 1957.

allantoic inoculation of virus seed into 10-day embryonated chicken eggs. After 4 days' incubation, allantoic fluids were harvested and titrated by hemagglutination against known antisera. Eight hemagglutinating units of antigen were used in the test.

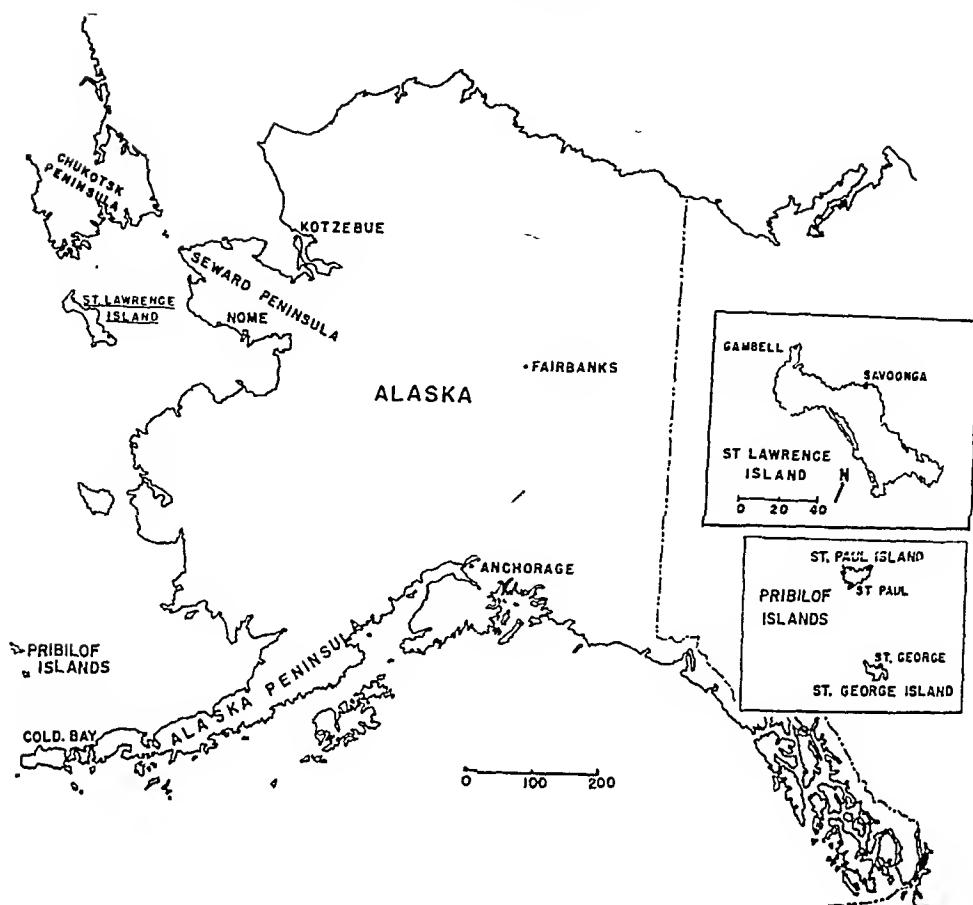

Pharyngeal swabs were obtained for culture from 38 ill persons during the latter stages of the outbreak in St. Paul. These were immediately planted in stock culture agar (Difco) slants and held at approximately 4° C. for 3 to 6 days until they could be transported to the Infectious Disease Laboratory, Arctic Health Research Center, Anchorage, for processing and bacteriological identification.

Figure 2 shows the chronological occurrence of illness during each outbreak. Two hundred and ninety-four (82 percent) of 358 St. Paul residents were ill between October 11 and November 2. Two hundred and sixty-two (87 percent) of 300 Gambell residents were ill between October 30 and November 18. Each outbreak was sharp, carried high risk of attack, and lasted approximately 3 weeks. The epidemic curves are similar and are characteristic of influenza.

Source of Outbreaks

Logs of all incoming traffic are maintained in each community. Examination of the St. Paul log and careful questioning of each passenger indicated that influenza was introduced into the village October 10 when four persons arrived by plane from Cold Bay, Alaska Peninsula. Since two of the passengers had influ-

Figure 1. The State of Alaska, with St. Lawrence, St. Paul, and St. George Islands.

are served by a Public Health Service physician in a small clinic-hospital.

St. Lawrence Island is in the northern part of the Bering Sea approximately 120 miles from Alaska and 40 miles from Siberia (fig. 1). It is inhabited by some 550 Eskimos residing in two communities of similar size, Gambell and Savoonga. At the time of the outbreak, all transportation to the island was by biweekly commercial air service from Nome, Alaska, to Gambell, and all persons traveling to Savoonga pass through Gambell. Influenza occurred in Savoonga also shortly after it was introduced into Gambell. However, details of the outbreak in Savoonga were not sufficiently complete to merit inclusion in this report.

Methods

Clinical observations were based on 192 patients (65 percent of the total 294 cases) who were seen at the clinic during the outbreak in St. Paul. Detailed clinical observations were not obtained in Gambell. Epidemiological observations were obtained in St. Paul by a survey of all households immediately after the epidemic, and in Gambell, primarily from health department nursing records and a can-

and sex, that is, risk of illness was only slightly greater for children than adults, and there was no difference between males and females (table 1).

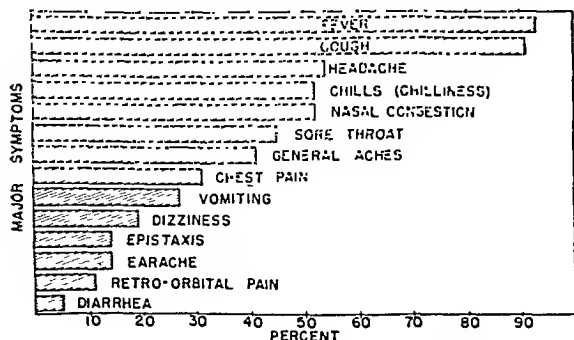

Table 2 compares the proportion of white and Aleut residents of St. Paul who were ill. Attack rates were similar among the 328 St. Paul Aleuts and 300 Gambell Eskimos (table 1) but distinctly lower among the 30 St. Paul white residents.

It is believed that the lower attack rate in white persons was at least partially due to their less frequent and intense exposure to the disease. There was little intermingling of white with other St. Paul residents except in the school and places of occupation. Nearly one-half of initial household cases occurred among school children, suggesting that the school played an important role in dissemination of the disease in the community. Of 14 white households (comprising an average of 2.1 persons), only 5 had illnesses. Two of the five had school children, whereas all nine households without illnesses consisted wholly of adults. On the other hand, all but 1 of 61 native households (comprising an average of 5.4 persons) had illnesses, and most of these households had school children.

Clinical Observations

The illnesses were generally mild and clinically characteristic of influenza in less remote populations. Figure 3 shows the frequency of various symptoms among 192 ill persons who were medically attended in St. Paul. Fever

Figure 3. Frequency of major symptoms among 194 influenza patients in St. Paul, 1957.

and cough were almost universal. The maximum recorded temperatures of febrile illnesses ranged from 99° F. to 106° F., with a mean maximum of 101.5° F. Thirty-seven percent of ill persons had productive cough, and it is noteworthy that 7 percent had hemoptysis. Painful deglutition was not observed, but many patients complained of "scratchy" throats. Nearly one-third complained of chest pain, usually substernal. Epistaxis was infrequent, but several individuals had severe nosebleeds which stubbornly resisted control. Earaches, predominately in children, complicated 14 percent of illnesses. Few of these progressed to drainage.

Of particular importance was the high frequency of lower respiratory complications (table 3). Since nearly all severely ill persons very likely sought medical care, frequencies were based on total illnesses by age and sex. One-third of illnesses had pulmonary or bronchial complications. Frequency of such complications, particularly those which were most severe, correlated directly with increasing age. Complications were equally frequent among males and females. Ten persons were hospitalized for pneumonia which was confirmed by chest X-ray. Five other persons had X-ray evidence and eight had clinical findings suggestive of pneumonia. Thus, 23 persons had pulmonary complications. There was no correlation between occurrence of lower respiratory complications and the presence of potentially pathogenic bacteria in the throats of 38 patients from whom cultures were obtained.

Two deaths were attributed to complications of influenza during the St. Paul outbreak. A 78-year-old man developed pneumonia complicated by congestive failure 9 days after onset of influenza. He died on the 11th day of illness despite intensive antibiotic therapy. A 27-year-old man developed right, middle lobe pneumonia 3 days after onset of influenza. Although he was hospitalized and given massive doses of antibiotics, including penicillin, tetracycline, streptomycin, and chloramphenicol, he steadily became worse and died on the third hospital day. A pure culture of *Staphylococcus aureus*, which was resistant in vitro to the antibiotics administered, was obtained from

enza-like illnesses October 20 and 22, they were not considered to be sources of the outbreak. A third passenger (A. M.) had departed from the Navy base, Adak, Aleutian Islands, October 9, and had stayed overnight at Cold Bay while awaiting transportation to St. Paul. In Cold Bay, at noon time on October 10, he met the fourth passenger (S. M.) en route from Anchorage, where he had just been discharged from the Army. The two men were closely associated during the subsequent 3-hour delay at Cold Bay and the 2-hour flight to St. Paul.

Approximately 8 hours after arrival, A. M. developed an influenza-like illness and all members of his family subsequently had similar illnesses, four beginning October 12 and one October 15. Meanwhile, S. M. celebrated his discharge and was jailed at noon, October 11, for disorderly conduct. He remained in jail until October 29, except for visits to the clinic for treatment of an influenza-like illness which began October 12. He could not have been an effective source of illness to the village.

The evidence, therefore, indicates that A. M. was probably the source of the outbreak. In

view of the fact that the two servicemen were not closely associated after arrival in the village, it is possible that A. M. was infectious to S. M. during the incubation period (8-12 hours prior to onset of symptoms).

The airline schedule showed that influenza was probably introduced into Gambell October 31 when a flight arrived from Nome carrying four passengers, all residents of Gambell and members of the National Guard who were returning from a course of training at Fort Ord, Calif. Three of the guardsmen had influenza-like illnesses in California. Upon arrival in Anchorage October 30, the fourth passenger developed influenza-like symptoms which continued after his arrival in Gambell. Seven members of his household and three neighbors became ill November 1, 2, 4, 6, and 7. The evidence, therefore, suggests that the fourth passenger acquired influenza from exposure before arrival in Alaska and was the direct source of the outbreak in Gambell.

Patterns of Morbidity

Five hundred and fifty-six (84 percent) of 658 residents in both villages were ill during the outbreaks. Attack rates were slightly lower in St. Paul than in Gambell. However, there were similar patterns of attack by age

is available on such an outbreak on St. Lawrence.

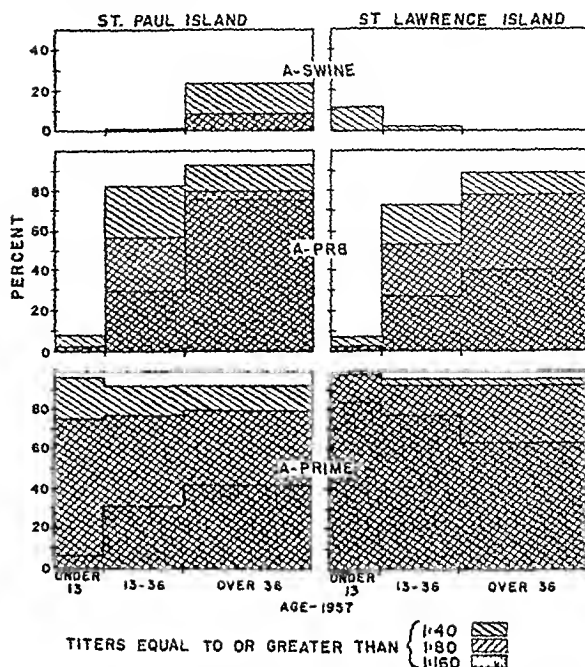

Nearly all persons tested in both villages had demonstrable antibodies to influenza A' indicating recent occurrence of the disease. Since serums were not obtained from very young children, the precise date of the last occurrence of influenza A' could not be determined.

Other Serologic Observations

Asian influenza infection rates could not be obtained by serologic methods because monovalent vaccines containing 200 chicken cell agglutinating (CCA) units of Asian virus per milliliter were administered during each outbreak. In St. Paul, two weekly 0.2-ml. doses of vaccine were given intracutaneously to each of 68 well persons beginning October 21, 12 days prior to onset of the last case. Likewise, single 0.1-ml. doses were given intracutaneously to 47 well Gambell residents, November 14, 4 days prior to onset of the last case. Obviously, there was insufficient time for vaccines to affect the course of the outbreaks. However, it was impossible to differentiate naturally acquired from artificially induced Asian strain antibodies among vaccinated persons.

Table 4 shows the distribution of HI titers to Asian influenza among vaccinated and non-vaccinated persons before and after the out-

Figure 5. Percentage of persons with stated preepidemic hemagglutination inhibition antibody levels to influenza A strains who were ill during St. Paul and Gambell influenza outbreaks, 1957.

breaks in each village. It is evident that demonstrable titers were infrequent and when present were low prior to the outbreak. In contrast, most nonvaccinated as well as vaccinated persons had demonstrable antibodies, generally of high titer, after the outbreaks.

bronchial aspirations. It is presumed that death was due to an overwhelming secondary infection by this agent.

The proportion of St. Lawrence Eskimos who had pulmonary complications is not known. There were, however, no deaths, and the health department nurse gained the impression from clinical observation that complications were infrequent.

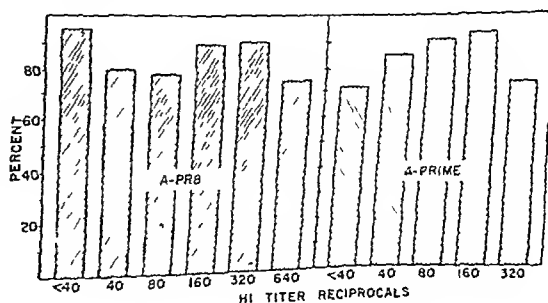

Prior Experience With Influenza

In view of the high morbidity during the two outbreaks, it was of interest to determine prior experience of these population groups with influenza A. There is, to our knowledge, no historical evidence that influenza occurred on St. Lawrence Island in 1918-19. Examination of medical logbooks, kept daily on all persons receiving clinical care on St. Paul Island during the years 1918-20, showed no evidence of an outbreak which could have been influenza. Figure 4 shows the proportion of persons in each village who had specific preepidemic HI antibody titers to preexisting strains of influenza A (including swine, A/PR8, and A') according to three broad age groups. The majority of persons tested in each village, includ-

ing those 37 years of age or older, had no demonstrable swine antibodies. These results may be contrasted with the serologic findings by Lackman that persons from Montana and Idaho who were born prior to 1920 had a high prevalence of swine antibodies (5).

Few persons in either village born after 1944 had demonstrable HI titers to A/PR8, whereas most persons born prior to 1944 had such antibodies. Several residents stated that an outbreak similar to that in 1957 occurred in St. Paul during the early 1940's. No information

Figure 4. Percentage of tested persons with preepidemic HI antibody titers equal to or greater than specified against influenza A strains of past years.

was no clinical evidence to suggest that any of the 23 cases of pneumonia in St. Paul were viral in origin or that the epidemic strain was any more virulent than Asian strains encountered elsewhere in 1957.

Summary

Asian influenza outbreaks occurred during October and November 1957 in the remote communities, St. Paul, Pribilof Islands, and Gambell, St. Lawrence Island, Alaska. Introduction of virus into each village could be dated precisely and in each instance was attributed to a returning serviceman.

Two hundred and ninety-four (82 percent) of 358 St. Paul residents and 262 (87 percent) of 300 Gambell Eskimos were ill during the outbreaks. Attack rates were higher among the Aleut than the white residents of St. Paul. Attack rates were higher among children than adults, but the difference was not so great as generally noted with Asian influenza.

The disease was generally mild and clinically similar to influenza noted elsewhere. There were two deaths in St. Paul. Pulmonary complications were somewhat more frequent than generally noted. There was, however, no evidence that such complications were viral in origin or that the epidemic strain of virus was more virulent than observed elsewhere.

Both villages had high prevalence, prior to the outbreaks, of HI antibodies to type A and A' influenza. Distribution of these antibodies by age indicated that type A influenza last occurred in 1943-44 and A' within recent years. Antibodies to the swine strain were infrequent in all age groups, and there was no historical evidence to indicate that influenza occurred in either community in 1918-19. Persons with type A and A' antibodies were as susceptible to illness during the outbreaks as persons without these antibodies. Prevalence of Asian influenza HI antibodies was low before but high after each outbreak.

Serums were obtained during the outbreak in St. Paul from 16 persons with illness. Only three had demonstrable A/Jap/305/57 antibodies. Data not shown have established that there were no essential differences in prevalence of HI antibodies to the other influenza strains before and after the outbreaks.

The magnitude of the outbreaks in each village and the evidence that residents had had extensive experience with type A influenza in the past strongly indicate that prior infection conferred no immunity to influenza in 1957. Figure 5 shows the proportion of persons who were ill grouped according to their preepidemic HI antibody levels to A/PR8 and A' strains.

Discussion

Influenza morbidity rates were generally higher in 1957 than during any influenza epidemic in recent years. An estimated 25 percent of the population of the United States was attacked (6). Rates ranging from 10 to 70 percent were reported in population groups of varying composition and size elsewhere in the world (7-14). However, to our knowledge, illness rates during the St. Paul and Gambell outbreaks were as high as any thus far reported.

The fact that each outbreak arose from a single introduction of virus, the date of which could be identified, afforded unusual opportunity for identifying the precise time limits of virus activity in each community. On the basis of the short duration of 3 weeks and the sharpness of epidemic curves, as well as clinical characteristics of illness, there is no doubt that nearly all illnesses occurring within this time were influenza. This raises the question as to why influenza morbidity was so high in these population groups.

The frequent and intense exposure resulting from unusually close community ties was highly favorable for rapid and wide dispersion of Asian virus. There was daily contact between households either at work, at school, at church, at play, or during social activities.

Lack of experience with preexisting influenza A strains could not have been responsible for the high attack rates. Not only had residents of each village been exposed to type A and A' strains but they actually had a higher preva-

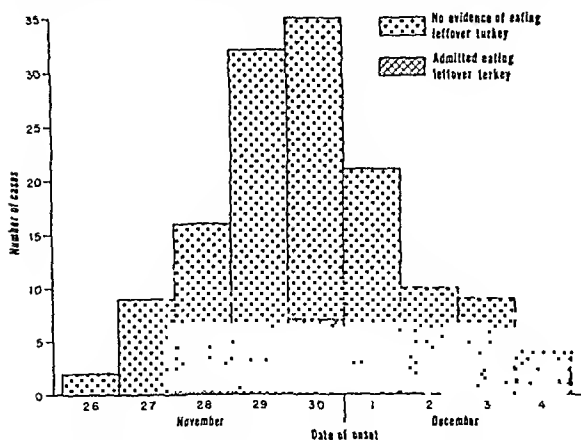

lence of HI antibodies than various population groups of comparable age in other Northwestern States (5).

The differences between attack rates in children and adults were not so striking as those noted by others (7, 10, 14, 15). Such differences are thought to reflect a broadening of experience with increasing age to the various antigenic components of influenza A virus (7). Older children and adults in these two villages had experienced both type A and A' infections, whereas young children had been exposed only to A' virus. However, there was no evidence on the basis of circulating HI antibody levels to indicate that past experience with either type A or A' strains reduced the risk of attack by Asian influenza. The degree of immunity may be related to intensity of exposure. It is possible that exposure was so intense during these outbreaks that immunity acquired from prior influenza A infections was not sufficient in most instances to prevent attack against the radically different Asian strain.

It was observed that swine HI antibodies were infrequent in St. Paul and absent in Gambell adults born prior to 1920. This is in contrast with the high prevalence of swine antibodies in this age group in most areas (5, 16-18). In a negative way this supports the hypothesis that a swine-like strain of influenza A virus was responsible for the 1918-19 pandemic since there was no evidence to indicate that the disease occurred in either community. This question is being investigated further during antibody surveys in other Alaskan native communities. In a small Indian village where approximately 20 percent of the population succumbed to influenza in 1918, all of 10 persons born prior to 1922 had swine HI antibodies in titers ranging from 1:40 to 1:320, whereas only 1 of 22 persons born after 1922 had such antibodies.

The frequency of pulmonary complications during the St. Paul outbreak was somewhat greater than that generally observed with Asian influenza (6, 7). However, severity of illness was not comparable to that during the 1918-19 pandemic or during the outbreak of influenza in 1949 among Eskimos of Victoria Island, Canada (19), where 20 percent died. There

Proportion of persons who admitted eating leftover turkey during outbreak of gastroenteritis.

An initial treatment of 2 gm. was given, followed by 1 gm. per day for 6 days.

The mess steward who sliced the turkey Thanksgiving morning became ill Friday afternoon, November 26. He reported that he had eaten a considerable amount of turkey while slicing it. His specimen was positive for *S. typhimurium*. This was apparently the first illness in the outbreak.

On November 29 and 30, illness was reported among some of the prison officers who on November 26 and 27 had eaten sandwiches which were prepared from turkey left from the Thanksgiving meal. Visits to the homes of the guards on sick leave revealed five ill persons, all of whom had eaten the turkey sandwiches but only one of whom had eaten turkey at the Thanksgiving meal. Cultures of specimens taken from all five were positive for *S. typhimurium*.

On the third day of the investigation, December 1, rectal swabs were obtained from 300 mess personnel who handled food. These swabs were placed in brilliant green tetrathionate broth. After incubation the broths were plated on brilliant green agar. Of these, 100, or 33 percent, were positive for *S. typhimurium*. About 40 percent of the persons infected denied enteric symptoms.

All of the infected food handlers were removed from mess duty and submitted specimens daily until two consecutive examinations were negative. The persistence of infections is shown in the table. Assuming infection oc-

curred on November 28, 30 percent of the patients harbored *S. typhimurium* for at least 14 days, and one person was positive after 4 months. Most of the individuals were not followed after two consecutive negative tests, but some who remained negative were continued at their request. No specimens were collected after 4 months.

Turkeys intended for the Thanksgiving dinner were delivered by a large meatpacking company on November 15. When, soon after delivery, the mess steward noticed that the turkeys were unfrozen, the supplier was requested to pick up these birds and to replace them with frozen turkeys. The replacements were received November 19, and the frozen turkeys were held at 28° F. until prepared in the prison butcher shop on November 24, the day before Thanksgiving. After roasting, the turkeys were returned to the butcher shop and sliced on the same chopping block where they were prepared for roasting. The block allegedly was cleaned with soap and water between the two operations.

Persistence of *Salmonella typhimurium* infection in 100 patients, determined by rectal swab culture

Days following infection	Patients with positive cultures

Slicing began about one o'clock Thanksgiving morning, November 25, and continued until just prior to dinner. The slices were placed in large pans about 6 inches deep and weighed. The amount necessary for dinner was steamed at 220° F. under pressure for 10 minutes. The turkey not needed for the meal was returned to the refrigerator without reheating. Turkey which was not reheated and that which remained on the serving line after dinner was used for the officers' lunches. Apparently,

Outbreak of Gastroenteritis Caused by *S. typhimurium* Acquired From Turkeys

DONALD C. MACKEL, M.S.

FRED J. PAYNE, M.D.

CARL I. PIRKLE, M.D.

AN OUTBREAK of gastroenteritis in a large, maximum-security penal institution afforded an opportunity to obtain additional evidence on the spread of *Salmonella typhimurium* by turkeys. In this instance the turkeys apparently were recontaminated after they were cooked.

Circumstantial evidence accumulated during recent studies indicates that fowl may be the vehicle of etiological agents in some outbreaks of diarrhea (1-5). Seldom, however, have the epidemiological indications been corroborated by bacteriological data, partly because the suspected items of food were not available when investigations were undertaken.

Nevertheless, it is manifest from observations that fowl may serve as the vehicle of *Salmonella*. In a study by Mosher and others (6) turkeys were implicated as the source of *Salmonella* infections on epidemiological grounds. In a 5-year study of the occurrence of *Salmonella* in fowl, Galton and associates recovered the organism from 14.5 percent of 434 chickens and turkeys examined (7). In one phase of the study they found that 16 percent of 1,244 specimens from fowl in 3 poultry processing plants were positive for *Salmonella*. The highest percentage of isolations were from the edible viscera, and *S. typhimurium* was the most prevalent type.

Description of the Outbreak

The outbreak first became evident during the afternoon and evening of November 27, 1954, when a number of prisoners reported to the hospital clinic complaining of severe nausea, vomiting, cramps, and diarrhea. Temperatures ranged from 99.6° F. to 104° F., and white

blood cell counts from 10,000 to 14,000 per cubic millimeter. No gross blood was noted in the stools. The illness was short except for those patients with sustained fever. Reports of illness characterized by these symptoms continued through November 30. Approximately 200 cases among the 2,700 prisoners were reported, 30 of the patients requiring hospitalization. Most of the ill persons were among the 300 men who worked in the prison mess or in the hospital.

Although an epidemic of food poisoning, presumably caused by *Salmonella*, was suspected when the first series of cases was reported, food histories obtained initially yielded few clues. The turkey left over from Thanksgiving dinner on November 25 was suspected since the prisoners involved had access to the kitchen and could have taken leftover food. This suspicion was confirmed later by two patients who reported that they were offered turkey sandwiches by fellow prisoners on November 27. In an unsigned questionnaire completed December 3 by 155 of the prisoners who had been ill, 25 admitted eating turkey other than that served at the Thanksgiving meal (see chart).

On November 29, when intensive investigation of the epidemic began, specimens on rectal swabs were obtained from 20 of the more acutely ill patients in the hospital. These were plated directly on SS agar and inoculated into tetrathionate broth to which brilliant green dye was added. After 18 hours incubation at 37° C., the broths were streaked to brilliant green agar. Sixteen, or 80 percent, of these cultures were positive for *S. typhimurium*. In vitro disk sensitivity tests indicated that the organisms isolated were sensitive to oxytetracycline. Therapy was started by administering this drug to 21 patients who had sustained fever.

Mr. Mackel, bacteriologist-epidemiologist, and Dr. Payne, an epidemiologist, were with the Enteric Disease Investigations Unit, Epidemiology Branch of the Communicable Disease Center, Atlanta, Ga., at the time of this study. Dr. Payne was chief of the unit. Both are currently assigned to the Communicable Disease Center Field Station, Phoenix, Ariz. Dr. Pirkle is medical director, Bureau of Medical Services, Atlanta.

Legal note . . . Municipal Control of Air Pollution

Constitutionality of Detroit Smoke Control Ordinance upheld in case involving municipal control of air pollution by vessels in interstate commerce. *Huron Portland Cement Co. v. City of Detroit*, 93 N.W. 2d 888 (1959).

The Smoke Abatement Code of the City of Detroit makes it unlawful to permit the emission within that city of smoke of a density equal to or greater than that designated as No. 2 on the Ringlemann Chart, and provides penalties for its violation.

A complaint filed by the city charged the Huron Portland Cement Co. with permitting two of its steamships operating in interstate commerce to emit dense smoke at the Port of Detroit contrary to the provisions of the code. The company then sued to enjoin the prosecution of the complaint, claiming the ordinance unconstitutional except insofar as any objectionable smoke was caused by the improper firing or other improper use of the equipment of the vessel. The court denied the injunction and held that the ordinance was constitutional. The company then appealed to the Supreme Court of the State of Michigan, claiming that (a) in the exercise of its power to control interstate commerce Congress had preempted the field by providing for inspection and control of American vessels on the Great Lakes, and (b) even if there had been no preemption by congressional action, the Detroit ordinance unduly burdened interstate and foreign commerce in matters where uniformity was necessary. The Supreme Court of Michigan rejected the contentions of the company and upheld the ordinance.

The constitutional grant of authority in Congress to regulate interstate and foreign commerce, the court noted, does not preclude all State action which may indirectly or incidentally affect that commerce. Unless it conflicts with or is superseded by legislation of Congress in the exercise of its superior authority in this

area, and as long as its effect on interstate commerce is only indirect and incidental, legitimate and reasonable State action with respect to a matter of local or internal concern is valid as an exercise of the police power of the State.

The court declared that the Federal legislation involved (46 U.S.C.A. Ch. 14) was intended primarily for the protection and safety of vessels, their passengers, crew, and cargo, and not designed or enacted for the protection of persons or property on land. The Smoke Abatement Code, the court held, was, on the other hand, intended solely to protect the health and welfare of the residents of Detroit by preventing the emission of dense smoke into the air, and it was not intended as a regulation of interstate commerce. In view of the differing subject matter, the Federal and local laws were thus held not to be in conflict, and the effect, if any, of the local ordinance on interstate commerce was declared to be only incidental to its purpose.

Turning to the question of the appropriateness of local air pollution ordinances as a reasonable exercise of the police power, the court stated that "by now it is sufficiently clear without citation of authority that excessive air pollution by dense smoke cannot be anything but harmful to the health and welfare of the community." The court also noted the increasing national concern with air pollution and referred to the Federal Air Pollution Research and Technical Assistance Act of 1955 (42 U.S.C. 1857) as indicating congressional approval and encouragement of local action to abate air pollution.

Recognizing the needs of our industrial society, however, the court concluded that a smoke

large amounts of this turkey also were obtained surreptitiously by the prisoners.

With the assistance of officials from the Food and Drug Administration, swabs were taken from various areas in the kitchen on November 30. The meat chopping block, other utensils, and the handles of knives used in cutting the meat were examined. Swabs were placed in brilliant green tetrathionate broth and streaked to brilliant green agar. All the cultures were negative for *Salmonella*.

None of the sliced turkey was available for examination, but the uncooked necks had been frozen for use in soup. One dozen of the frozen necks were selected randomly, divided into four pools, and homogenized in a food blender with 150 ml. of brilliant green tetrathionate broth in each pool. *S. typhimurium* was recovered from one of the four pools.

Discussion

Epidemiological and bacteriological data indicate that this outbreak of gastroenteritis was caused by turkey meat infected with *S. typhimurium*. The case studies indicate that illness occurred only in the group who had eaten the turkey which was not reheated after being sliced. This strongly suggests that (a) the turkeys were infected originally, (b) the chopping block was contaminated when the birds were prepared for roasting, and (c) the cooked birds were recontaminated from the chopping block. Reheating apparently was sufficient to destroy *Salmonella* on the contaminated meat.

The severity and duration of symptoms in this outbreak are consistent and characteristic of *S. typhimurium* infections. Patients treated with oxytetracycline responded well clinically. The persistence of infections compares closely with those reported by Mosher and others (6),

who observed an infection 4 months after the beginning of an outbreak.

Summary

Studies were made of an outbreak of gastroenteritis involving about 300 inmates of a penal institution. All of the patients investigated had eaten roasted turkey which had been sliced on the same chopping block on which the uncooked fowl had been prepared. No other persons became ill after eating only reheated meat from the same birds.

Salmonella typhimurium was recovered from more than 100 persons who had eaten the contaminated meat and from turkey necks which had been frozen.

Legal note . . . Municipal Control of Air Pollution

Constitutionality of Detroit Smoke Control Ordinance upheld in case involving municipal control of air pollution by vessels in interstate commerce. *Huron Portland Cement Co. v. City of Detroit*, 93 N.W. 2d 888 (1959).

The Smoke Abatement Code of the City of Detroit makes it unlawful to permit the emission within that city of smoke of a density equal to or greater than that designated as No. 2 on the Ringlemann Chart, and provides penalties for its violation.

A complaint filed by the city charged the Huron Portland Cement Co. with permitting two of its steamships operating in interstate commerce to emit dense smoke at the Port of Detroit contrary to the provisions of the code. The company then sued to enjoin the prosecution of the complaint, claiming the ordinance unconstitutional except insofar as any objectionable smoke was caused by the improper firing or other improper use of the equipment of the vessel. The court denied the injunction and held that the ordinance was constitutional. The company then appealed to the Supreme Court of the State of Michigan, claiming that (a) in the exercise of its power to control interstate commerce Congress had preempted the field by providing for inspection and control of American vessels on the Great Lakes, and (b) even if there had been no preemption by congressional action, the Detroit ordinance unduly burdened interstate and foreign commerce in matters where uniformity was necessary. The Supreme Court of Michigan rejected the contentions of the company and upheld the ordinance.

The constitutional grant of authority in Congress to regulate interstate and foreign commerce, the court noted, does not preclude all State action which may indirectly or incidentally affect that commerce. Unless it conflicts with or is superseded by legislation of Congress in the exercise of its superior authority in this

area, and as long as its effect on interstate commerce is only indirect and incidental, legitimate and reasonable State action with respect to a matter of local or internal concern is valid as an exercise of the police power of the State.

The court declared that the Federal legislation involved (46 U.S.C.A. Ch. 14) was intended primarily for the protection and safety of vessels, their passengers, crew, and cargo, and not designed or enacted for the protection of persons or property on land. The Smoke Abatement Code, the court held, was, on the other hand, intended solely to protect the health and welfare of the residents of Detroit by preventing the emission of dense smoke into the air, and it was not intended as a regulation of interstate commerce. In view of the differing subject matter, the Federal and local laws were thus held not to be in conflict, and the effect, if any, of the local ordinance on interstate commerce was declared to be only incidental to its purpose.

Turning to the question of the appropriateness of local air pollution ordinances as a reasonable exercise of the police power, the court stated that "by now it is sufficiently clear without citation of authority that excessive air pollution by dense smoke cannot be anything but harmful to the health and welfare of the community." The court also noted the increasing national concern with air pollution and referred to the Federal Air Pollution Research and Technical Assistance Act of 1955 (42 U.S.C. 1857) as indicating congressional approval and encouragement of local action to abate air pollution.

Recognizing the needs of our industrial society, however, the court concluded that a smoke

control ordinance may be said to be reasonable if it does not unduly hamper industry. Thus, the court conjectured, if the ordinance had attempted to prevent the emission of all smoke or if adequate means of smoke control were not available, another question might have been raised. The Detroit ordinance, however, the court pointed out, sought to outlaw only the emission of smoke of such density as to be readily prevented by the use of modern smoke equipment. The court stated, "All it costs is money." It concluded that the ordinance was a reasonable exercise of local police power and did not unduly interfere with interstate commerce.

With respect to the company's second contention, the need for uniformity, the court reasoned that the Detroit ordinance should not be held invalid simply because of the possibility that ordinances at other ports, applicable to the company's vessels, might be more stringent and require changes in equipment. It was suggested that the company might avoid this possibility by employing the most modern devices available to reduce smoke to the least possible density. Although the court conceded that the subject might well call for uniform Federal legislation, short of such action, the court held the Detroit ordinance was within the proper exercise of the police power.

A Bulwark Against Senility

Philadelphia has undertaken a constructive experiment to prevent mental deterioration among the aged.

In an effort to demonstrate that senility is not inevitable and can be prevented, the Frederic R. Mann Recreation Center was opened in November 1958. The first of its kind in the Nation, the center provides to adults 60 years of age and older who are capable of traveling to and from the center unaided, the services of an occupational therapist, three recreation leaders, a psychiatrist, psychologist, psychiatric social worker, public health nurse, and physician. It has a capacity of 200.

The idea grew from studies by Dr. Maurice E. Linden, director of mental health in the Philadelphia Department of Public Health, who found that one-third of all mental hospital admissions in the city were in the upper age group.

Dr. Linden has long held that senility is a misnomer. It is his belief that aged persons need not break down mentally if they are given a constructive social environment and opportunity to develop hobbies and other occupational, mental, and social interests.

The center is a cooperative enterprise of the Pennsylvania State Department of Public Welfare and the Departments of Public Health and Recreation of Philadelphia.

An article describing the center's activities will appear in a forthcoming issue of *Public Health Reports*.

Signs

and

Symptoms

of trends in public health

Hot and humid working conditions increase fatigue in workers, endanger their health, and diminish their efficiency, observes Dr. Lucien Brouha of the Haskell Laboratory of Industrial Toxicology, Wilmington, Del.

He points out the need for efficient ventilation, properly insulated sources of heat, screens, special clothing, and special tools and methods to enable men to work as far as possible from a source of heat, rest periods in cooled and dehumidified air, and a measured intake of water in the right quantity and at the right time.

Water should be drunk from cups, he says, to cut down on amount of swallowed air and to permit measurement. He feels also that salt loss can generally be offset by adding enough salt to the food at every meal.

According to the New York Interdepartmental Health Resources Board, 4 out of 5 hospitals in New York State, and 9 out of 10 in New York City, refuse to admit alcoholics.

« »

The Office of Vocational Rehabilitation reports a record of 74,320 persons rehabilitated during fiscal year 1958, 3,380 more than in 1957. An additional 18,584 have been prepared for work but have not yet found employment.

Estimates indicate that the men and women rehabilitated during the year will increase their earnings from \$22 million to about \$148 million in their first full year of employment. They will contribute about 114 million man-hours to the Nation's labor force.

Nearly 15,000 of these people had been receiving public assistance at an annual cost of \$14 million, whereas the total, one-time cost of rehabilitating them was about \$13 million.

aration of shellfish for marketing, and control of harvesting from closed areas. Information on bacteriological criteria and inspection of certified shippers is provided in the appendixes.

A companion to PHS Publication No. 83, part II, 1957 revision, this manual supersedes its 1946 edition. Both parts were prepared with assistance from State shellfish control agencies, industry associations, and interested U.S. and Canadian Federal agencies.

Indians on Federal Reservations in the United States. A digest. Aberdeen Area. PHS Publication No. 615, part 3; 1959; 73 pages.

Brief information about Federal Indian Reservations in Nebraska, North Dakota, South Dakota, Iowa, Michigan, Minnesota, and Wisconsin is contained in this digest. The population groups, their homes, education, and income, and their health status and services are discussed. Included also is a description of the location, ownership, and topography of reservation land.

Review of the Second Conference on Progress and Potentials in Leprosy Investigations. PHS Publication No. 641; 1958; 36 pages.

Abstracts of selected papers provide a brief review of conference highlights. A substantial portion discuss the deficiencies in knowledge about leprosy. Other reports deal with clinical observations, evaluation studies, and the epidemiological and immunological aspects. The discussions of obscure mycobacterial diseases of man and animals are also covered.

Bibliography of Military Psychiatry, 1952-1958. PHS Publication No. 693; 1959; by Charles Roos and Jeannette Barry; 83 pages.

A continuation of the "Bibliography of Military Psychiatry, 1947-52," these 736 references relate directly to the military situation or involve United States military personnel. They are arranged in 17 categories and many are briefly annotated. An author index is provided.

Although intended primarily for military psychiatrists and psychologists, this bibliography should be a useful tool for civilian mental health personnel and medical librarians.

Seasonal Variations of Births in the United States, 1948-54. *Vital Statistics—Special Reports; Selected Studies*; vol. 47, No. 4; Apr. 24, 1959; pages 127-143.

Current seasonal patterns in the birth rate are obtained and comparisons made between the years covered and earlier years. Supported by tables and charts, they show variations between races and different geographic regions of the Nation.

Derivation of a seasonal index and its use in adjusting series of monthly birth rates are demonstrated. Types of fluctuations and different methods of computing the index are also considered.

Highlights of Progress in Mental Health Research, 1958. PHS Publication No. 659; 1959; 40 pages; 20 cents.

Selected studies by the National Institute of Mental Health's scientists and grantees during 1958 are described. Areas covered include biological and behavioral aspects of schizophrenia, biochemical bases of behavior, brain and behavior, learning and perception, psychopharmacology, and drugs and behavior. Epidemiology, personality development, the child's relation to his family, the disturbed child, alcoholism, aging, and psychosomatics are also included.

The work and findings discussed point up the multidisciplinary approach that has characterized mental health research during the past few years.

Grant and Award Programs of the Public Health Service. Volume I. Policy and information statement on research grants. PHS Publication No. 415; revised 1959; 19 pages.

Purpose and availability, application procedures, restrictions, and other details are described. In addition to general information, spe-

cific information is given about grants for pilot projects, constructing and equipping health research facilities, and field investigations in cancer, neurological and sensory disorders, and mental health.

Organization and Staffing for Local Health Services, January 1, 1958. PHS Publication No. 682; 1959; by Clifford H. Greve and Josephine R. Campbell; 60 pages; 40 cents.

The organization and staffing of 1,480 local health units are analyzed.

Tables and charts show extent of coverage of the Nation by local health organizations, selected characteristics of organized areas, financial capacity of those areas and their expenditures for public health, and public health personnel employed by official health agencies and by other official agencies.

VD Fact Sheet. PHS Publication No. 341; 15th revision; 1959; 22 pages. Latest statistics on venereal disease incidence, prevalence, and treatment. Supersedes previously published data.

Tuberculosis. PHS Publication No. 30 (*Health Information Series No. 33*); revised 1959; 13 pages; 10 cents, \$6.50 per 100. Revised to emphasize the newest developments in detection and treatment. Also describes the bacillus, its transmission, and the course of the disease, dispelling many popular beliefs about tuberculosis.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications other than its own.

Federal Publications

Natural Fluoride Content of Communal Water Supplies in the United States. *PHS Publication No. 655; 1959; 111 pages; 60 cents.*

The 1,903 communities listed in this census of naturally fluoridated water supplies have at least one water source containing 0.7 ppm or more fluoride, the minimum level for optimum protection from dental caries.

Statistical information is presented for naturally fluoridated water sources by fluoride content, State, and size of community.

Health Statistics From the U.S. National Health Survey. Impairments by type, sex, and age. United States, July 1957-June 1958. *PHS Publication No. 584-B9; 1959; 28 pages; 25 cents.*

Estimates of visual, hearing, and speech defects, loss of extremities, paralysis, and other neurological or orthopedic defects and abnormalities are presented. The tables show impairments involving bed disability days and the number and percent of impairments caused by injury. Medical care status and major activity of handicapped persons are also tabulated.

Appendixes carry technical notes on methods, definitions, and coding classifications, and the questionnaire on which the information was obtained.

Annual Report, U.S. Department of Health, Education, and Welfare, 1958. *HEW Publication (Unnumbered); 1959; 262 pages; 75 cents.*

Progress and cooperation comprise the theme of the Secretary's report to the President.

Activities of the Social Security Administration, Public Health Service, Office of Education, Food and Drug Administration, Office of Vocational Rehabilitation, and Saint Elizabeths Hospital are described in detail. Short discourses on the functions of the American Printing

House for the Blind, Gallaudet College, and Howard University are also presented.

Pointing out that international programs exist in all phases of the Department's work, the report emphasizes the basic needs of all peoples.

Glaucoma References. *PHS Publication No. 664; 1959; 15 pages; 10 cents.*

Methods used in diagnosing early glaucoma, medical and surgical treatment, hereditary and geriatric factors, glaucoma surveys, community casefinding programs, and vision conservation programs are the major topics of this annotated bibliography for professional workers and students in the field of public health.

Pertinent films and pamphlets are also cited with brief descriptions of their content, use, and availability. Annotations are grouped under the major categories of community aspects, clinical aspects, films, and pamphlets.

Salaries of Local Public Health Workers, August 1958. *PHS Publication No. 656; 1959; 40 pages.*

Data in this report, taken from questionnaires submitted to local health departments, boards of education, and nonofficial health agencies, cover salaries of some 12 occupational groups of professional personnel. Frequency distributions of salaries are shown by population of area served and by Bureau of Census region.

Scientific Directory and Annual Bibliography, National Institutes of Health, 1959. *PHS Publication No. 667 (Public Health Bibliography Series No. 24); 1959; 100 pages.*

Listing all key personnel, staff members with doctorate degrees, and visiting scientists with tenure of a year or more, the directory reflects the organizational structure of the

National Institutes of Health, Public Health Service, as of February 1959.

The bibliography itemizes papers published during 1958 which present original work of scientists at the Institutes. Alphabetized by senior author with the entries listed under the organizational entity to which he was attached when the work was done, it indicates the accomplishments of each unit.

Individual contributions are recognized in the alphabetical index of all authors and names in the directory.

The National Cancer Institute. *PHS Publication No. 458; revised 1959; 24 pages; 20 cents.*

Organization and functions of the National Cancer Institute, National Institutes of Health, are discussed in detail. Included are descriptions of the types of research conducted, the national chemotherapy program, and programs to assist in early diagnosis and treatment of cancer. Specific information is given about professional training and research grants.

Screening for Glaucoma. *PHS Publication No. 666; 1959; 23 pages; 25 cents.*

Eight glaucoma detection programs conducted in various communities prior to February 1957 are described. Directed to those planning casefinding surveys, this booklet covers sponsorship, test population and procedures, referral, and followup techniques.

A summary of operations and findings is given for each program discussed.

Manual of Recommended Practice for Sanitary Control of the Shellfish Industry. Part I. Sanitation of shellfish growing areas. *PHS Publication No. 33; revised 1959; by Eugene T. Jensen; 36 pages; 45 cents.*

Administrative and technical procedures for the States, Public Health Service, and shellfish industry are suggested. Separate sections deal with laboratory methods, growing area survey and classification, prep-

An evaluation of narcotics controls discloses that our Nation's statutes are not sufficiently flexible in view of new discoveries in synthetic analgesics. Suggested changes include a redefinition of addiction and uniform national and international laws.

Addiction Liability and Narcotics Control

NATHAN B. EDDY, M.D., and HARRIS ISBELL, M.D.

AMONG the most effective measures for the prevention of drug addiction are the Federal laws and international treaties controlling the production and distribution of the drugs of addiction and the source materials from which these drugs are derived. The application and administration of these laws have steadily become more complex. A large number of synthetic drugs with pharmacological effects and addiction liability similar to that of morphine have been discovered and have created some difficult problems of classification and control. It is now also known that substances, such as the barbiturates and the amphetamines, covered by the food and drug but not by the narcotic laws, are susceptible to abuse and may produce a different addiction from that caused by the opiates. It is the purpose of this paper to review the historical origin of the present narcotic laws and to discuss changes in them which seem desirable in the light of recent knowledge.

Definition of Addiction

In 1950, at the request of the Commission on Narcotic Drugs of the United Nations, the Ex-

Dr. Eddy is chief, Section on Analgesics, National Institute of Arthritis and Metabolic Diseases, and Dr. Isbell is director, Addiction Research Center, National Institute of Mental Health, Public Health Service.

pert Committee on Addiction-Producing Drugs of the World Health Organization drafted a definition of addiction (1). The committee said, "Drug addiction is a state of periodic or chronic intoxication, detrimental to the individual and to society, produced by the repeated consumption of a drug (natural or synthetic). Its characteristics include: (1) an overpowering desire or need (compulsion) to continue taking the drug and to obtain it by any means; (2) a tendency to increase the dose; (3) a psychic (psychological) and sometimes a physical dependence on the effects of the drug."

In its third report (2) in 1952, the expert committee wrote an explanation of the characteristics of addiction designed particularly to express its view on a distinction between addiction and habituation. In 1957, to clarify further this distinction, the expert committee reworded its definition of addiction without material change in its meaning (3).

This definition received some acceptance but also much criticism. It was not meant to be pharmacological, nor strictly speaking scientific, but practical, and was intended to include the diverse substances currently under international narcotics control. State and national narcotics laws and regulations and international narcotics conventions are designed to prevent or at least limit abuse of cocaine and marihuana as well as of opium and the potent analgesics. Though all of these substances are commonly and loosely termed narcotics, their properties

QUESTIONS AND ANSWERS ON SMALLPOX AND VACCINATION

By J. P. LEAKE, Surgeon, United States Public Health Service

The following questions are not infrequently asked by physicians in regard to variola and its prevention. Part of the answers given are supported by good evidence, part by conclusive evidence, but much, unfortunately, is only opinion, a personal weighing of such evidence as is at hand; yet each of the questions should have a tentative answer, according to the best light available. Further information may change the answers given here. Though for nearly every statement that can be made concerning smallpox some support can be found in the literature, a few of the observations here recorded are original. It is hoped that many of the gaps in our knowledge of smallpox and vaccination may soon be filled. Of all infectious diseases prevalent in the United States this disease is the most completely preventable by public health measures.

1. *What is the best method of vaccination?*

Probably the "multiple pressure or prick" method.¹ This consists of a shallow, tangential pricking of the cleansed, but not irritated, skin with a needle, through a drop of smallpox vaccine, covering an area not greater than one-eighth of an inch (3 millimeters) in diameter. This gives little chance of accidental infection and the eruption is typical. Acetone

JANUARY 28, 1927, pp. 221-238

Dr. J. P. Leake provided specific and detailed answers to 23 questions about smallpox. He covered vaccination techniques, reactions, and complications, the necessity and methods for protecting vaccine potency, and the diagnosis, course, and virulence of the disease.

ics of the National Research Council discussed the problem at length at its 20th meeting, January 11, 1959, and passed unanimously a resolution embodying its views (5).

International Control

The first effective effort toward obtaining international action to control the traffic in opium and the dangerous drugs obtained therefrom was the conference of the International Opium Commission convened in Shanghai in February 1909, on the initiative of the U.S. Government. The successive steps or agreements on international narcotics control, again reflecting the development of thought on this problem, have progressed as follows:

International Opium Convention of 1912. Designed to bring about the gradual suppression of the abuse of opium, morphine, and cocaine, as also of the drugs prepared or derived from these substances which give rise or might give rise to similar abuses. The contracting parties agreed to enact effective laws or regulations for the control of the production and distribution of raw opium. A less definite obligation was imposed with respect to smoking opium, and the contracting parties' best efforts were to be used with respect to morphine and cocaine and their salts to restrict their import and export to authorized persons and to enact laws limiting exclusively to medical and legitimate purposes the manufacture, sale, and use of these dangerous drugs.

Geneva Narcotics Convention of 1925. Intended to impose somewhat more specific obligations with respect to control of national and international trade. It established the Permanent Central Opium Board to watch continuously the course of international trade in the drugs covered by the 1912 convention, collect and examine statistics, and obtain and communicate to all parties explanations of apparently excessive accumulations of the dangerous drugs in any country.

Convention of 1931. Limited the manufacture and regulated the distribution of narcotic drugs by requiring all countries, whether or not parties to the convention, to supply annual estimates of their needs of stated derivatives of opium and coca leaves, based solely on medical

and scientific requirements. Thereafter, each country was obligated to limit its manufacture of each of the drugs in accordance with its estimate and to supply periodically to the Permanent Central Opium Board statistics of actual manufacture, consumption, importation, and exportation of those drugs. In other words, the convention contemplated the adjustment of world manufacture to legitimate world demand, the control of all channels of distribution, both national and international, and provision for a recording system of all narcotic drug operations. It entrusted to international organizations the task of supervising and coordinating throughout the world. The convention specified the drugs to be controlled and made some provision for additions to the list.

Protocol of 1946. Transferred to the Commission on Narcotic Drugs of the United Nations Economic and Social Council the functions previously carried out by the Opium Advisory Committee of the League of Nations.

Protocol of 1948. Established an international procedure, analogous in principle to that of our Opiates Act of 1946, whereby new drugs found to have dangerous addiction liabilities are promptly brought under the control imposed by the 1931 convention, the definitive finding in this case being made by the World Health Organization.

Opium Protocol of 1953. Designed to limit definitely the production of opium to medical and scientific needs and to establish the areas of production and sources of world supply. This protocol has not yet become effective.

Single Convention. Originally intended to incorporate into a single agreement by codification the provisions of the various international narcotics conventions but actually undergoing elaboration. It is still in the drafting stage.

Need for Flexibility

It is apparent that, initially, thought and effort toward narcotics control were centered upon the crude materials, opium and coca leaves, or upon the potent drugs obtained from them, morphine and its derivatives and cocaine. In the United States marijuana was added to the list of substances controlled because of evidence

differ so widely that they are similar only in being subject to abuse and in creating social dangers. Of necessity, any definition attempting to cover all of them had to be very broad.

National Control

When control was first considered (1909-12) and for a considerable time thereafter, only cocaine and opium and its alkaloids were taken into account. Their abusive use was recognized and considered of sufficient importance to warrant strict control, even at the expense of placing a burden upon drug manufacturers, pharmacists, and physicians, as well as upon the government which had to implement the control. Relatively few individuals abused both opiates and cocaine, the effects of which are different and in some respects opposite; yet both were called narcotics and both were subjected to the same control measures.

An excellent chronological review of the steps in the development of national and international control of narcotic drugs was published in 1953 (4).

Merely listing the principal acts of Congress on this subject with their chief intent will indicate the progress of events and the development of thought on the problem of control:

February 9, 1909. Prohibition of importation of opium and its preparations and derivatives except for medicinal purposes and absolute prohibition of importation of smoking opium.

January 17, 1914. Prohibition against exportation of opium and cocaine and salts, and derivatives and preparations thereof, except to a country which regulated the entry of such drugs; absolute prohibition of exportation of smoking opium.

January 17, 1914. Prohibitive tax upon opium manufactured for smoking purposes.

December 17, 1914. Harrison Narcotic Law, an internal revenue measure by tax and registration limiting the availability of narcotic drugs to medical and scientific uses, and regulating production, manufacture, and distribution, through channels of medical supply to the dispensing registrants, the qualified practitioner, and druggist.

May 26, 1922. Narcotic Drugs Import and

Export Act, an extensive revision of the act of 1909 authorizing the importation of such quantities only of opium and coca leaves as were found to be necessary for medical and legitimate needs. Importation of any form of narcotic drug except crude opium and coca leaves was prohibited. Exportation of manufactured drugs was permitted under a system of control designed to assure their use for medical needs only in the country of designation.

June 7, 1924. Amendment to the Narcotic Drugs Import and Export Act prohibiting the importation of opium for the manufacture of heroin.

June 14, 1930. An act establishing the Bureau of Narcotics in the Department of the Treasury.

August 2, 1937. The Marihuana Tax Act. Imposition of registration and occupational tax on all persons who produced, imported, manufactured, sold, or transferred marihuana.

August 9, 1939. Contraband Seizure Act, authorizing confiscation of any vessel, vehicle, or aircraft used to facilitate transportation and so forth of contraband narcotics or marihuana.

December 11, 1942. Opium Poppy Control Act, prohibiting the growth of the opium poppy in the United States, except under special license issuable when need is shown for domestic production for medical and scientific uses.

July 1, 1944. A statute making the Federal narcotic laws applicable to pethidine (meperidine, Demerol) under the statutory designation "IsonipECAINE."

March 8, 1946. The Opiates Act, or Robertson Amendment, establishing a general procedure for the expeditious application of control measures to any drug found to be dangerous from the addiction-liability standpoint.

1955-59. The Karsten bill, designed, among other things, to implement our obligation under the 1948 protocol to bring new substances under new narcotics control. This bill is still pending. Consideration is being given to its possible amendment looking to greater flexibility in our system of narcotics control, tailoring, so to speak, the degree of control to the degree of risk to public health. Among those giving thought to the desirability of such amendment, the Committee on Drug Addiction and Narcot-

conditions any such agent could be controlled only in the same manner as morphine, our narcotics laws are in a sense hampering the search for a nonaddicting pain-relieving drug.

Clinical experience and direct addiction experiments indicate that cocaine does not produce physical dependence, and abrupt withdrawal after prolonged use is not followed by an abstinence syndrome. In the amounts taken by addicts in the United States, however, cocaine can cause a dangerous psychosis, and taken chronically it causes tachycardia, insomnia, and anorexia with resultant impairment of nutrition. Cocaine does produce strong psychic dependence, and its prolonged use is undoubtedly detrimental, hence its control by the narcotics laws. Similarly, marihuana does not produce physical dependence manifested by a withdrawal syndrome. Here, too, control is exercised because of the harmful effects of the drug under conditions of abuse.

In recent years the Addiction Research Center of the Public Health Service Hospital at Lexington, Ky., has been investigating the possibility of development of physical dependence during prolonged administration of barbiturates, meprobamate, and similar drugs. It has been shown conclusively that physical dependence could develop when large doses of these substances were taken chronically and that a characteristic abstinence syndrome followed abrupt withdrawal (9-11). It was also shown, however, that no clinically significant degree of dependence developed in persons taking only 0.4 gram or less daily of secobarbital or pentobarbital, that is, two to four times the usual daily oral dosage (12). It is clear from the work at Lexington that the symptomatology of abstinence with barbiturates or meprobamate is distinctly different from abrupt withdrawal of an opiate. Further, physical dependence or addiction with barbiturates and meprobamate has been observed in clinical practice (13-15).

It should be clear that addiction and its relation to narcotics control are complex qualitatively and quantitatively and that our present system of control is not realistically adjusted to this complexity. The Opiates Act says, for example, that the criterion for control

of a new substance shall be ability to produce or sustain an addiction similar to that of morphine or cocaine. If, in this connection, the word similar is interpreted as implying quantitative similarity, difficulty must be encountered in bringing under control a substance of low addiction liability, substantially less than that of codeine, as has been the case with propoxyphene, a weak synthetic analgesic of the methadone group. This particular situation might be clarified by making the criterion for control "qualitatively similar to morphine," leaving to the judgment and experience of the responsible authority whether or not the addiction liability of a particular substance is sufficient in degree to constitute a risk to public health and thus warrants narcotics control. It is possible that control at the manufacturing and wholesale level only would be adequate for substances of low addiction liability where the risk to public health is small, leaving retail trade in drugs of minor addictive potential free of narcotics control, not requiring narcotics prescriptions, narcotics records, and the like.

It has been pointed out that our narcotics laws and regulations, while providing for exempt preparations of codeine and other substances derived from morphine and even for preparations containing up to a certain concentration of morphine itself, make no provision for exempt preparations of synthetic analgesics. Since it is known that the "natural" alkaloids, morphine and substances derived from it, and the synthetic analgesics vary in addictiveness and therefore in risk to public health, both the "natural" and synthetic classes of drugs should be treated in the same way. If exempt preparations are safe and permissible in the "natural" class, they should be safe and permissible in the synthetic class. On the other hand, if the argument is that there is some risk in exempt preparations of morphine and opium because of the possibility of abuse by the consumption of multiple doses, a similar risk would be expected with exempt preparations of synthetic substances with morphine-like addiction liability. The Expert Committee on Addiction-Producing Drugs of the World Health Organization has pointed out repeatedly the risk of

of widespread abuse. The picture changed with the discovery and introduction into medicine of the first synthetic morphine-like pain-relieving drug (pethidine, meperidine, Demerol), the tremendous impetus to research on analgesics which followed that discovery, and the important advances which have been made in the study of addiction. It would seem desirable to consider how the picture has changed and to try to understand the implications of the change.

Pethidine was but the first of a very large number of substances prepared entirely by synthesis in the laboratory which exhibited in animals and man wide differences in analgesic and physical dependence properties. These substances also are widely different in chemical structure. Some are built upon moieties of the morphine molecule. Others differ so greatly in chemical structure that the tentative relationships of structure and analgesic action described by Braenden, Eddy, and Halbach (6) as recently as 1955 cannot always be discerned.

It is well recognized from clinical experience and direct evaluation experiments under controlled conditions that substances derived from morphine differ in analgesic potency and addiction liability and present different degrees of risk to public health, ranging from the great danger of heroin, the main drug in the present-day illicit traffic in the United States, to relatively low risk with codeine, which with proper therapeutic use rarely results in addiction.

Examples of all the synthetic chemical types have been evaluated for addiction liability as well as for analgesic effect and have exhibited a range of activity from much greater than morphine to substantially less than codeine. In this connection the expert committee (7) has stated "that synthetic analgesic drugs differ from one another in addiction liability just as do drugs derived from natural sources such as opium; that members of each class must be considered individually with respect to inherent risk and therapeutic advantage; and that the risk of addiction through the use of synthetic drugs is neither greater nor less than the risk encountered through the use of morphine, related opium alkaloids, or substances derived therefrom."

For the natural alkaloids, that is, for sub-

stances which are modifications of morphine whether occurring in opium or produced in the laboratory, the 1931 convention recognized a difference and established groups I and II for which control regimens would be different. Group I was further subdivided into subgroup (a) comprising morphine and similarly addicting substances, and subgroup (b) comprising ecgonine, thebaine, and other drugs regarded as not themselves addicting but convertible into drugs capable of producing addiction. Group II was established to include codeine, dionin, and related substances, likewise then regarded by many as not capable of producing addiction but also convertible into addiction-producing drugs. The distinction was drawn between subgroup (b) and group II not on theoretical but on practical grounds, namely, that the drugs in group II were very extensively used in medicine all over the world, whereas those in subgroup (b) were hardly used at all by the medical profession (8). All measures of control were applicable to all drugs in group I (both subgroups), but a somewhat modified control was permitted for the drugs of group II. For the latter the substances themselves were controlled internationally in essentially the same way as those in group I with only minor modifications such as greater leeway in estimates of needs and other statistical matters. However, under the convention, compounds of the drugs in group II, if they were adapted to normal therapeutic use, were exempted from international narcotics control.

The U.S. laws do not recognize a distinction in the regimen of control such as that between group I and group II of the 1931 convention except insofar as specifically described preparations of not greater than specified concentration may be sold as conditionally exempt preparations without a narcotics prescription. These limited exemptions were authorized before the discovery of pethidine and the many other synthetics, and the Opiates Act of 1946 made no provision for their extension to a preparation of any synthetic. This situation must be discouraging to pharmaceutical manufacturers and may act as a deterrent to research programs designed to develop analgesics of low addictiveness. Since under present

a drug (natural or synthetic). Three qualitatively different types may be recognized, the characteristics of which are:

Opiate addiction, of which morphine addiction is the prototype, has three major components: tolerance, physical dependence, and emotional (psychic or psychological) dependence. Tolerance, the need for an increasing dose to produce an effect, is an inevitable accompaniment of opiate addiction but does not develop equally to all effects nor necessarily parallel to physical dependence. Physical dependence is an altered physiological state which requires continued administration of a drug to prevent the appearance of a characteristic illness, termed an abstinence syndrome. Emotional dependence is substitution of the use of the drug for other adaptive behavior, the use of the drug becoming the answer to all of life's problems. The abstinence syndrome is a self-limited illness, beginning with yawning, perspiration, rhinorrhea, and lacrimation, progressing to dilatation of the pupil, waves of gooseflesh, twitching of various muscle groups, hot and cold flashes, and restlessness which may become extreme. There is elevation of systolic blood pressure, respiratory rate, and rectal temperature. Retching, vomiting, and diarrhea ensue in the more severe syndromes. There is complete or almost complete anorexia and rapid loss of weight. The time course varies: it may appear in 2 to 4 hours after the last dose of drug and run its course in not much more than 48 hours; it may be delayed in onset for as much as 48 hours and persist for at least 14 days. The abstinence syndrome is precipitable in whole or in part when physical dependence is present by the administration of an opiate antagonist (nalorphine). Opiate addiction is always associated with a drive or compulsion to continue taking the drug and to obtain it by any means.

Cocaine addiction has as its chief characteristic emotional (psychic or psychological) dependence. Tolerance does not develop, there is no physical dependence, and consequently no abstinence syndrome follows withdrawal of the drug. There may be a drive or compulsion to continue taking the drug, depending upon the degree of psychic dependence. In some areas cocaine abuse is a periodic indulgence progress-

ing to a toxic psychosis, characterized by paranoid delusions.

Marihuana (cannabis), like cocaine, produces emotional (psychic or psychological) dependence only. Physical dependence does not develop and there is no abstinence syndrome. Also little, if any, tolerance develops. Abuse is often sporadic, consisting of a periodic intoxication characterized by elation and distortion of time and space perception.

The amphetamines (benzedrine, *d*-amphetamine) also produce only emotional dependence. There is no physical dependence, no abstinence syndrome, and very little tolerance. Chronic intoxication resulting from abuse resembles in symptomatology chronic intoxication with cocaine.

Barbiturate addiction is characterized by emotional (psychic or psychological) dependence, physical dependence, and partial tolerance, but it implies habitual consumption of amounts far in excess of usual therapeutic doses. While barbiturate addiction has the same three components as opiate addiction, there are two significant differences. First, with the opiates there is evidence to indicate that physical dependence may begin to develop with the first dose; with the barbiturates there is no evidence that significant physical dependence occurs in patients who consume only usual therapeutic doses. Second, the abstinence syndromes with the opiates and with the barbiturates are characteristically different. The barbiturate abstinence syndrome is characterized by anxiety, nervousness, disturbances of cardiovascular responses, twitching of muscle groups, and tremor progressing to convulsions of petit mal or grand mal type and confusion or both, disorientation, and hallucinations predominantly visual. The abstinence syndrome, as with the opiates, is self-limited. Some degree of compulsion to continue taking the drug will occur in barbiturate addiction.

Meprobamate, as well as other hypnotics, may produce an addiction with the same characteristics as the barbiturates.

Non-Opiates and Narcotics Control

The consensus today, nationally and repeatedly affirmed by the Expert Committee on Ad-

addiction through the use of multiple doses of preparations of strongly addicting substances (16, 17) and that admixture with other substances cannot be relied upon to avoid such risk (18).

In contradistinction to what has just been said about exempt preparations of morphine, of opium, and of synthetics with comparable addiction liability, a very desirable measure of flexibility in narcotics control would be provided by extension of the exempt preparation provisions to substances of low addiction liability, irrespective of origin. Provided such a modification does not contravene any international agreement, the substances in pure form would be subjected to narcotics control, but preparations or combinations of them, in mixtures with other therapeutic non-narcotic agents from which the addicting substance would not be readily recoverable, would be exempt from narcotics control.

Our national laws make no provision for control of a substance not itself addicting but readily convertible into another substance known to be addicting. This lack could lead to grave danger, allowing free trade in the parent substance and giving opportunity for clandestine transformation into the addicting agent. It would seem desirable to control the convertible substance as one would control any substance into which it can be converted.

The categories of control now provided by law or suggested herein for a realistic relationship between degree of narcotics control and risk to public health then should include: full control for substances having high or intermediate addiction liability; the oral prescription list of substances or mixtures having little addiction liability; exempt status for preparations and mixtures of safe concentration from the standpoint of abuse; and control at the manufacturing and wholesale level only for substances with very low addiction liability. In addition, there would be advantage in an official listing of certain compounds to which no narcotics control is presently applied. This listing would include substances related to those under some degree of narcotics control or other substances with clinical usefulness which, because of their general chemical or

pharmacological characteristics, might be considered to have addiction potentiality, but concerning which there is no conclusive evidence of such liability. The listing would make interested parties aware that the status of such compounds would be reviewed from time to time as experience accumulated so that if evidence of addiction or other abuse appeared the proper degree of control would be applied.

To maintain the flexibility of narcotics control and to keep the degree of control applied to all drugs commensurate with the degree of risk to public health, the authority designated by law to make a finding in this field should be empowered to revise such a finding in the direction of either greater or less control, including complete removal of a substance from narcotics control, when experience warrants such revision. The designated authority too should have for its guidance adequately representative technical advice and, before a finding is made, recommendations of that advisory body should be published and an opportunity provided for a hearing and presentation of additional or counter evidence by any interested party, as in the 1946 Opiates Act procedure. Also it is to be understood that any revision of national control with respect to a particular substance must be consistent with our obligations under international agreements.

Addiction Redefined

Two general criteria for narcotics control are available, "addiction-producing and addiction-sustaining similar (or qualitatively similar) to morphine," as in our 1946 Opiates Act; or "liable to the same kind of abuse and productive of the same kind of harmful effects," as in the 1948 protocol. With either would it not be well to substitute for the heterogeneous, albeit comprehensive, definition of addiction of the World Health Organization's expert committee, a definition which would be specifically descriptive of the various qualitative types of addiction already alluded to? The following text is suggested:

For an understanding of the need and scope of narcotics control, drug addiction may be defined as a state of periodic or chronic intoxication produced by the repeated consumption of

Training in Epidemiology

A course in applied epidemiology will be offered at the Rocky Mountain Field Training Station of the Communicable Disease Center, Public Health Service, in Denver, Colo., November 16-20, 1959.

Designed primarily for physicians who investigate disease outbreaks or who have administrative responsibility for such investigations, this course serves as a review for experienced health administrators and as a guide to physicians new to public health.

Emphasis is placed on developing an understanding of the use of epidemiological techniques to solve problems pertaining to preventable diseases. Lecture-discussion sessions and audiovisual aids are used in the presentations. Group participation is stressed through group solution of epidemiological problems, seminars, and panel discussions. Registrants will be expected to attend all sessions of the course.

Further information and application forms may be obtained from: Chief, Communicable Disease Center, Public Health Service, 50 Seventh Street NE., Atlanta 23, Ga., Attention: Chief, Training Branch; or from: Public Health Service, Region VIII, First National Bank Building, Denver 2, Colo.

diction-Producing Drugs of the World Health Organization, is that, although abuse occurs, narcotics control should not be extended to the amphetamines, the barbiturates, or other sedatives. There are several reasons for this opinion.

Clinical experience leads us to believe that most persons will handle and use these drugs as prescribed and will not develop a chronic intoxication or addiction. This is not believed to be true of the opiates, cocaine, or marihuana. Cocaine and opium are derived from plants whose production is limited to certain areas of the world from which they are transported to processing and consuming countries. International control is absolutely necessary. Amphetamines, barbiturates, and other hypnotics are produced primarily by local manufacturers, making control of imports and exports less of a problem and control of these drugs by local measures effective. Furthermore, indications for the medical use of the amphetamines or of the hypnotics are more numerous and far broader than indications for the opiates, cocaine, or marihuana. The barbiturates are widely used in the treatment of epilepsy, peptic ulcer, hypertension, mild neuroses, and simple insomnia. Meprobamate is finding wide application in mental disease. The amphetamines are used medically as anorexic agents, for the treatment of narcolepsy, to elevate mood in depressed individuals, to elevate blood pressure in shock, and in many other situations.

On the other hand, the main indication for use of opiates is the presence of severe pain; the use of cocaine is practically limited to local anesthesia; and marihuana has no medical indication. To place the restrictive regulations of narcotic laws on the amphetamines, the barbiturates, and other sedatives would hamper proper medical use and would not be justified in view of the relatively low public health risk which is already mitigated through regulations in respect to these drugs in the food and drug statutes, both Federal and State.

Conclusions

It is concluded that implementation of suggestions made in the discussion with respect to changes in our national narcotics control regimen would:

1. Remove any distinction between substances of natural or purely synthetic origin with respect to the possibility of exempt preparations.
2. Provide flexibility of narcotics control based upon the degree of risk involved, varying from full control for substances of high addiction liability to control at the manufacturing and wholesale level only for substances of low addiction liability. Alternatively for the latter group, control of the pure substance and exemption from control of its preparations with other therapeutic agents might be provided.
3. Bring local regulations into line with the international narcotics conventions.
4. Encourage the development of much needed analgesics of an efficacy more or less comparable to codeine which might have low addiction liability by making possible a commensurate degree of narcotics control.
5. Clarify the meaning of addiction in relation to narcotics control, by descriptive definition and by basing the application of control to new substances upon properties qualitatively similar to those of morphine.

the period 1952 through 1958. The next phase will be concerned primarily with the development and testing of methods for conducting a national epidemiological study of the disease.

The hospital survey was undertaken first not only because the need for hospital care is an important aspect of the health problem presented by this disease, but also because information about hospitalized patients is more readily available than any other data on prevalence since most hospitals maintain an index of diseases which makes possible the identification of cystic fibrosis patients. It is generally believed, however, that the number of hospitalized patients is only a fraction of the total number of children with the disease.

Method

The survey covered all hospitals in the continental United States listed in the American Hospital Association and the American Osteopathic Hospital Association directories for 1958, except psychiatric institutions. A stratified sample of about 9 percent, or 616, of the 6,723 listed nonpsychiatric hospitals was selected. All 296 hospitals approved for pediatric residency were taken. A sample of other hospitals was selected with probability roughly proportionate to the number of hospital beds. The sampling rates ranged between 2 and 100 percent for the hospitals with the smallest and largest numbers of beds, respectively (table 1).

Questionnaires were sent by regular mail to the sample hospitals. Hospitals that did not return them within 2 weeks were sent a follow-up letter by certified mail. Toward the end of the fourth week of the survey, telephone calls were made to the larger hospitals with pediatric residencies that had not responded. Returned questionnaires were edited for completeness and consistency, and special letters were sent to hospitals that reported incomplete or inconsistent information. The survey lasted 5 weeks, from January 8 through February 13, 1959.

Interpretation of Data

The questionnaire requested information on the number of different patients discharged with a diagnosis of cystic fibrosis, the number of dis-

charges for these patients, and the number of discharges that were due to death. Separate information was requested for each calendar year during the 7-year period 1952-58. Because cystic fibrosis (indexed under fibrocystic disease of the pancreas) was listed for the first time in the fourth edition of the American Medical Association's Standard Nomenclature of Diseases and Operations, published in 1952 (6), that year was chosen as the beginning of the study period. The standard nomenclature is the basis for disease indexing in the vast majority of hospitals in the United States. Additional information relating to the characteristics of the discharges for 1957 was also requested, but these data are not considered in this report. The final section of the form requested information about the type and currency of diagnostic indexing, which was useful in evaluating the quality of the reported data.

Evaluation of the quality of the data reported by the hospitals for the 6-year period 1952-57, shown in table 2, was based entirely on the completeness and consistency of the data on the returned form. Data for 1958 were excluded because a substantial number of hospitals had not yet completed their diagnostic indexing for that year. According to the evaluation criteria, about 80 percent of the hospitals reported complete and consistent information for the entire 6-year period. By the cutoff date no data were reported for almost 10 percent of the hospitals:

Table 1. Sampling strata of the national hospital survey of cystic fibrosis

Type and size of hospital	Sampling rate (per cent)	Number of listed hospitals	Sample size
All hospitals in AHA and AOHA directories (psychiatric institutions excluded)-----	9.16	6,723	616
Hospitals with pediatric residencies-----	100.00	296	296
Other hospitals-----	4.98	6,427	320
1,000 or more beds-----	100.00	37	37
300-999 beds-----	20.00	425	85
200-299 beds-----	10.00	508	51
100-199 beds-----	5.00	1,197	61
Less than 100 beds-----	2.00	4,260	86

A substantial number of hospitalized cases of cystic fibrosis with a relatively high fatality rate indicates one aspect of the health problem presented by this disease, first differentiated only some 20 years ago.

A National Hospital Survey of Cystic Fibrosis

MONROE G. SIRKEN, Ph.D., MARIAN M. CRANE, M.D., MORTON L. BROWN, B.A.,
and ELIZABETH R. KRAMM, Ph.D.

CYSTIC FIBROSIS, also known as fibrocystic disease of the pancreas and as mucoviscidosis, has been increasingly recognized during recent years as one of the major diseases of childhood. As recently as 1938, Andersen (1) differentiated the disease from other superficially similar conditions. It is known to be a familial disease involving malfunction of various exocrine glands, but the basic defect underlying its pathological manifestations is not yet understood.

Clinically, cystic fibrosis is most often evidenced by chronic digestive and respiratory disturbances appearing usually in infancy or early childhood. Without treatment these generally progress to nutritional failure or severe respiratory involvement, or both, and to death before school age. Other manifestations include intestinal obstruction in the newborn, heat prostration, and, more rarely, cirrhosis of the liver. Cure is not possible, but with the use of recently

developed methods of diagnosis and treatment prognosis has become more hopeful. When the disease is recognized in its early stages or in milder forms, development of serious symptoms can often be prevented. Antibiotics help to control the susceptibility to respiratory infection, but once pulmonary lesions are established they tend to persist and can be fatal or seriously handicapping.

The frequency of the disease in the general population is not known, but it appears to be high. On the basis of a small survey of hospitals and pediatricians, it was estimated that during the period 1945-49 the disease occurred 7 to 10 times per 10,000 live births (2). The condition has been found in about 3 percent of the autopsies performed in children's hospitals (3). Early clinical experience with the disease indicated that death occurs in infancy or early childhood for a majority of positively diagnosed cases (4). Recently, however, survival beyond childhood of patients with cystic fibrosis has been noted with increasing frequency (5).

The Children's Bureau and the National Office of Vital Statistics are cooperating in a project designed to obtain information on the magnitude and characteristics of the health problem presented by cystic fibrosis. In the first phase of the study, reported here, data have been obtained by a mail survey on the number of children with a diagnosis of cystic fibrosis who were cared for in hospitals during

Dr. Sirken is chief and Mr. Brown is a statistician in the Actuarial Analysis and Survey Methods Section, National Office of Vital Statistics, Public Health Service. Dr. Crane is research pediatrician and Dr. Kramm is a health research specialist, Division of Research, Children's Bureau, Social Security Administration. The survey was supported in part by funds from the National Institute of Allergy and Infectious Diseases, Public Health Service.

Table 4. Estimated number of patients, discharges, and deaths with a diagnosis of cystic fibrosis reported by hospitals, United States, 1957

Type of hospital	Patients	Discharges	Deaths
All hospitals-----	2, 525	3, 229	359
Hospitals approved for pediatric residency---	1, 186	1, 544	237
Other hospitals-----	1, 339	1, 685	122

rience was the same as that reported by hospitals included. The adjusted frequencies were subsequently inflated by the inverse of the sampling rate to obtain the national estimates presented in this report. The adjustment and inflation of the tabulated frequencies were made independently for each sampling stratum. Data for two hospitals which specialized in research on cystic fibrosis and which reported the highest caseloads were excluded prior to adjusting the estimates for nonreporting hospitals approved for pediatric residency. The trend figures for 1952-57 were based on hospitals providing complete and consistent information for the 6-year period, and the frequencies were adjusted and inflated as for the 1957 data.

A qualifying statement is necessary regarding the estimates of the number of cystic fibrosis patients presented in this report. The hospitals were requested to report the number of different patients who were discharged each year. No attempt was made, however, to obtain identifying data on individual cases such as would be needed to eliminate duplicate re-

porting of cases from year to year within the same hospitals or from different hospitals within the same year.

Since the survey was conducted with a sample of hospitals, the estimates presented in this report are subject to sampling errors. The approximate sampling errors in the estimates of patients, discharges, and deaths for 1957 are shown below. The chances are about 19 out of 20 that differences due to sampling variability between the estimate based on the sample of hospitals and the figure that would have been obtained from a survey of all hospitals is less than twice the sampling error. The sampling errors of the estimates for other years were roughly the same as those for 1957.

Type of hospital	Percent sampling error		
	Patients	Discharges	Deaths
All hospitals-----	10	10	10
Hospitals not approved for pediatric residency-----	20	20	30

Estimates for 1957

About 2,500 patients with a diagnosis of cystic fibrosis were discharged from hospitals in the United States during 1957 (table 4). This estimate is probably somewhat higher than the true figure because patients discharged with this diagnosis from more than one hospital during 1957 were counted by each hospital. Approximately 95 percent of the 2,500 patients were under 20 years of age. For these 2,500 patients, about 3,200 discharges were reported, indicating multiple discharges from the same hospital during 1957 for many of them. About 360 hospital deaths were attributed to cystic fibrosis, or ap-

7 percent did not respond and 2.4 percent indicated inability to comply with the request for data within the specified time. (About one-fourth of the nonresponding hospitals replied within 1 month after the cutoff date but too late to be included in this analysis.) Another 11 percent of the hospitals returned forms which were evaluated as incomplete or inconsistent for 1 or more years between 1952 and 1957.

One exception was made in evaluating the returned forms. A large pediatric residency hospital provided annual data for the number of patients discharged and the number of deaths but could not provide information on the total number of discharges within the time limits. Discharges were estimated by assuming

a ratio between discharges and patients based on data reported by another large pediatric residency hospital.

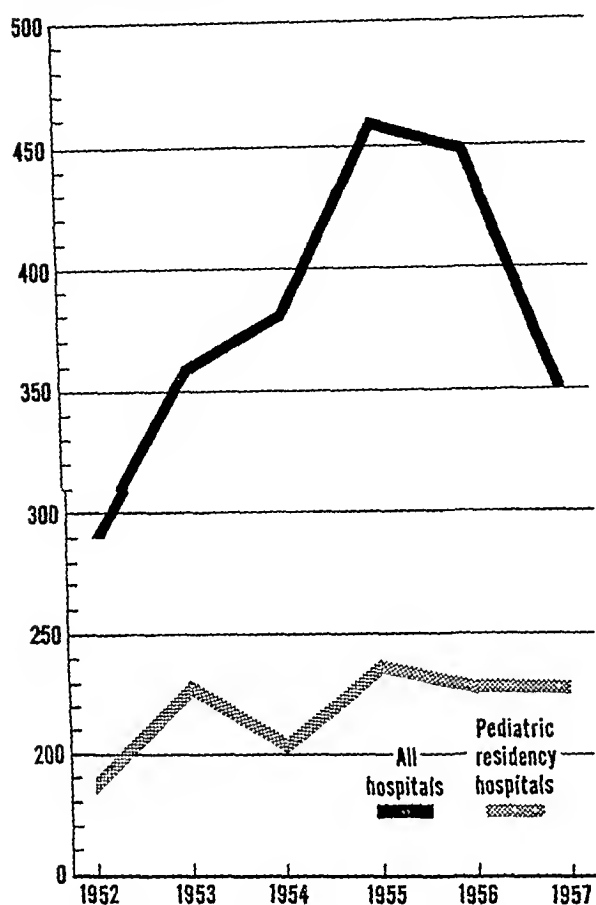

As might have been expected, the reported hospital data were more complete and consistent for the more recent years. About 89 percent of the hospitals reported complete and consistent information for 1957 as compared with 82 percent for 1952 (table 3).

Tabulations of reported frequencies of patients, discharges, and deaths during 1957 were based solely on hospitals providing complete and consistent information for that year. The tabulated frequencies were appropriately adjusted for the hospitals excluded from the tabulations under the assumption that their expe-

Figure 2. Trend in the number of deaths attributed to cystic fibrosis in hospitals, United States, 1952-57

centers. Greater awareness on the part of physicians and improved diagnostic techniques have resulted in earlier recognition of the milder forms of the disease, many of which do not require hospitalization. The cystic fibrosis patients hospitalized in 1957, therefore, probably represented a smaller proportion of the total number of cases known to physicians than did the patients hospitalized in 1952, even though the number of persons hospitalized for the disease had increased 50 percent from 1952 to 1957.

Data are yet to be obtained on the ratio of persons hospitalized with cystic fibrosis to total persons with the disease. There are diagnosed cases which have not been admitted to a hospital as well as undiagnosed cases. Concerning the former, Dr. Harry Shwachman of the Children's Medical Center in Boston, a center long

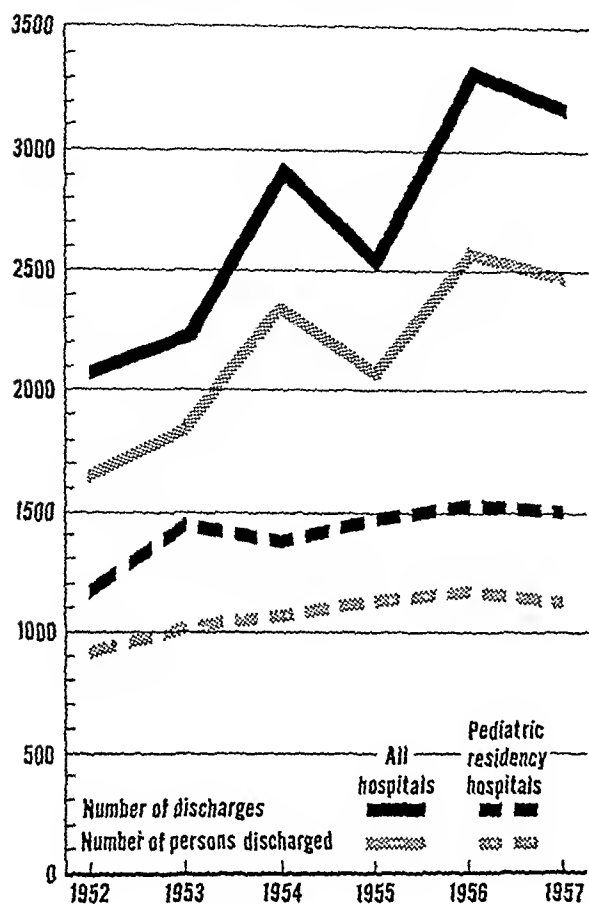

known for its interest in cystic fibrosis, has estimated that of the 500 children with this condition followed in his office or clinic practice, at least 25 percent have never been hospitalized. Dr. Gordon E. Gibbs in the department of pediatrics of the University of Nebraska has stated that of 40 children with cystic fibrosis directly or indirectly under his care only 4 have ever been admitted to a hospital. It seems likely that the 2,500 cystic fibrosis patients discharged from hospitals in the year 1957 represent only a small part of the total number of patients with the disease, although the exact proportion is still uncertain.

That the number of hospital discharges with a diagnosis of cystic fibrosis is nearly a third greater than the number of persons so discharged in the same year indicates that many of the patients are so ill as to need repeated hospital admissions within a short period. On the basis of an estimated 2,800,000 hospital discharges for patients under 15 years of age from July 1957 through June 1958 (7), cystic fibrosis was the diagnosis of roughly 1 in every 1,000 hospital discharges among children.

The estimate of the number of annual hospital deaths attributed to cystic fibrosis obtained from this survey is supported by information from another source. The National Office of Vital Statistics has obtained an estimate of the number of deaths attributed to cystic fibrosis by coding the disease separately in its analysis of a 10 percent sample of 1958 death certificates. Such data have not been obtained nationally in previous analyses of death certificates because cystic fibrosis has hitherto been included in the residual category "Other diseases of pancreas."

Analysis of the sample of 1958 death certificates revealed an estimated 560 deaths in the United States attributed to cystic fibrosis in that year. Of these, about 400 occurred in hospitals. With due regard to sampling error, this is consistent with the finding from the hospital survey of an estimated 359 hospital deaths attributed to cystic fibrosis in 1957. The finding that about 160 (over one-fourth) of the cystic fibrosis deaths reported on 1958 death certificates occurred outside hospitals is evidence that the children are not always hospitalized even during the most acute phases of the illness.

Figure 1. Trend in the number of patients and discharges with a diagnosis of cystic fibrosis from hospitals, United States, 1952-57

proximately 1 out of every 7 patients with the diagnosis.

Although hospitals with pediatric residencies represented less than 5 percent of all hospitals, they accounted for almost 50 percent of the patients and discharges and almost 65 percent of the deaths (table 4). The two children's hospitals, Babies Hospital in New York City and Children's Medical Center in Boston, in which physicians have for a long time had special interest in this disease, accounted for about 6 percent of the patients and discharges and 7 percent of the deaths reported for 1957.

Trends for 1952-57

The annual number of patients with cystic fibrosis increased by about 50 percent during the 6-year period 1952-57, or from about 1,700

to about 2,500 (table 5, fig. 1). During the same period the population under 20 years of age, which included virtually all the diagnosed cases of cystic fibrosis, increased only between 15 and 20 percent. Most of the increase in cystic fibrosis patients occurred in hospitals not approved for pediatric residency, the number in pediatric residency hospitals remaining relatively constant during the entire period.

The number of discharges also increased by about 50 percent, or from 2,100 in 1952 to about 3,200 in 1957, and again most of the increase occurred in nonpediatric hospitals (table 5, fig. 1).

The number of hospital deaths attributed to cystic fibrosis reached a peak during 1955 and then declined in 1957 (table 5, fig. 2). During the 6-year period, the proportion of deaths ranged between 14 and 25 percent of the total number of patients discharged with the disease. It is difficult, however, to draw conclusions about the death trend from these data since most of the annual changes in the number of deaths in hospitals may reflect sampling variability.

Discussion

This survey has provided data on the number of patients with a diagnosis of cystic fibrosis discharged from hospitals in the United States for each of the 6 years from 1952 through 1957. However, the numbers for individual years cannot be added together to obtain a total for the period since the same persons could have been reported for 2 or more years. Even within a single year there could have been duplicate reporting for patients discharged from more than one hospital during that year.

In the years covered by the survey there has been a continuous and substantial increase in the annual number of patients hospitalized with a diagnosis of cystic fibrosis. Since this increase is about three times greater than the increase in the size of the population under 20 years of age, it is only partially explained by this factor. The increase may be interpreted as indicating greater success in recognizing the disease. Most of the increase is reported from hospitals that do not have a pediatric residency and is probably the result of an increased awareness of the disease outside pediatric

A pilot program in Bolivia demonstrates the feasibility of smallpox eradication by mass vaccination at the sources of the disease.

Smallpox Eradication

HARALD FREDERIKSEN, M.D., M.P.H., D.T.M.&H.

NEMESIO TORRES MUÑOZ, M.D.

ALFREDO JAUREGUI MOLINA, M.D., M.P.H.

NATIONS freed of smallpox are confronted by a continuous threat of reinvasion from the endemic foci remaining in the world. The concept of control, limited to the protection of a national population and resigned to the existence of endemic foci in other nations, requires a perpetual and elaborate system of defense: education, general vaccination in infancy, routine revaccination, reporting, isolation, disinfection, quarantine, investigation, contact vaccination, general revaccination, international notification, certification, and medical inspection. However, the frequent movement of the disease across international boundaries shows that, even with elaborate control measures, no nation can permanently prevent reinfection.

Dr. Frederiksen, who is now program officer, Division of International Health, Public Health Service, served in 1957 and 1958 as director of the Servicio Cooperativo Interamericano de Salud Pública, a joint agency of the Republic of Bolivia and the United States. Dr. Torres Muñoz was associate director of the agency, and Dr. Jauregui Molina, director of SCISP's vaccination service.

Only the eradication of smallpox would end the threat of the disease, as well as the otherwise unending efforts and costs of control. What are the prospects for eradication once all nations join in an unrelenting attack on smallpox wherever transmission persists?

Rather than evaluate hypothetical obstacles to eradication it seems appropriate to cite the circumstances, methods, and results of the pilot program in Bolivia undertaken by the Servicio Cooperativo Interamericano de Salud Pública. With one of the highest attack rates for smallpox, Bolivia was one of the principal endemic foci in the American Hemisphere (1). Because of a unique combination of adverse factors, Bolivia was a testing ground for the feasibility of smallpox eradication through the progressive elimination of the endemic foci remaining in the world.

The Setting

Landlocked in the heart of the South American continent, Bolivia has climate and scenery that range from steaming tropical to Alpine. Most of its 1 million square kilometers is tropi-

Estimates of 1958 deaths by cause for the population under 15 years indicate that cystic fibrosis ranked higher as a cause of death than such other diseases as diabetes, rheumatic fever, and poliomyelitis. Cystic fibrosis is comparable to these diseases not only as a cause of death but also in the lasting and handicapping disability it often causes in patients who survive.

Summary

A nationwide hospital sample survey, conducted between January 8 and February 13, 1959, obtained information about hospital patients discharged with cystic fibrosis. The survey provided the following national estimates:

1. In 1957, about 2,500 patients were discharged from hospitals with a diagnosis of cystic fibrosis. Of these, 95 percent were under 20 years of age. The total number of discharges for that year was approximately 3,200, indicating repeated hospitalization for many of the patients. About 360, or 14 percent of the patients, were discharged by death. (A sample of 1958 death certificates indicated that roughly one-fourth of all deaths due to cystic fibrosis occur outside hospitals.)

2. From 1952 to 1957, the number of hospitalized patients with the disease increased by approximately 50 percent. There was a corresponding increase in the total number of discharges. Most of the increase in the number of patients and discharges occurred in hospitals other than those approved for pediatric residency. The estimated number of deaths in 1957 was approximately 20 percent greater than the estimate for 1952, but this difference

may be attributed to sampling error. During the intervening years, a somewhat higher number of deaths was reported.

Although estimates of the number of patients discharged from hospitals with a diagnosis of cystic fibrosis are probably far short of the prevalence of the disease in the general population, the fact that in 1 year 2,500 persons were hospitalized and that 1 out of every 6 or 7 was discharged by death affords a striking picture of the seriousness of this disease.

climate revealed that only 37.6 percent of those vaccinated within the past 10 years were immune, and of those vaccinated 10-40 years previously, only 3 percent were immune. The low percentages cannot solely be attributed to a loss of immunity and lack of revaccination.

The prevalence of pockmarked persons by age groups and department gives an indication of the previous incidence of smallpox (table 1). It might be recalled that for every three pocked individuals there has been one death from smallpox with the assumption of a fatality rate of 25 percent.

The highest prevalence of pockmarked persons is in the La Paz Department, particularly among those over 40 years of age with 40.9 percent pockmarked. The greatest prevalence of pockmarked individuals in this department may be attributed to the cool dry climate and the relative density of the population and the means of communication, as compared with the remainder of Bolivia.

The correlation of smallpox with cool dry climate is supported by the seasonal peak observed in Bolivia during the dry winter months.

The percentages of pockmarked persons in five provinces of the La Paz Department along the shores of Lake Titicaca, quite identical in respect to topographic, climatic, socioeconomic, and racial factors, confirm the correlation between population density and the prevalence of pockmarked individuals (table 2).

It is interesting to note that immunity fol-

lowing smallpox, at least to vaccination, is not absolute. In a sample of 434 pockmarked persons over 10 years of age, only 56.5 percent displayed immune reactions. Nevertheless, a second attack in the same individual seems to be a rare occurrence, which is attributed to the longer duration of immunity to smallpox than to vaccination.

The assessment of the consequences of the disease must also include blindness. In Bolivia smallpox ranks as the principal cause of blindness, with more than one-third of the inmates of institutions for the blind dating their history of disability from an attack of smallpox.

The Campaign

Cochabamba, the central department of Bolivia, was the epicenter of an epidemic wave with 87 outbreaks of smallpox reported during 1957. Emergency efforts were undertaken during the latter half of that year. Simultaneously, preparations were made for a nationwide campaign. The preparations included a successful request for a budget of \$125,000 and supporting legislation, importation of equipment and vaccine, development of methods, preparation of a plan of operations, and selection and training of personnel. The emergency efforts to combat the epidemic in Cochabamba, undertaken with personnel and equipment borrowed from other programs, provided a test for the methods and plan of operations.

cal lowland along the cayman-infested, headwaters of the Amazon. The majority of the 3.3 million people of Bolivia live on the highland plateau, the Altiplano, at an elevation of 3,500 meters, where La Paz, the seat of government, is located.

Bolivia is thinly populated, with a density of 3.3 persons per square kilometer. Means of communication are limited. Much of the country is inaccessible by road, and most of the existing roads are unsurfaced and frequently are blocked by floods and landslides. Bolivia is one of the few countries of the world with areas still awaiting exploration.

While ethnic distinctions are blurred, the population can be divided sociologically into a literate minority, largely of Spanish descent, and an illiterate majority of Indian stock. The Indians usually have only a little knowledge of the official language, Spanish.

A number of devastating wars and revolutions have impeded development. The country, while potentially rich, remains undeveloped, and the per capita income is low. The combination of adverse factors has limited health services to a minority.

Past Control Efforts

Data indicated that vaccinations in Bolivia were deficient in quantity and and quality. In

115 samples totaling 47,742 persons from the highland plateau, the valleys, and lowlands, the proportion of those previously vaccinated fluctuated between 11.1 percent and 94 percent, with a median of 69.3 percent. While this percentage may seem fairly satisfactory, a closer examination reveals a less reassuring situation. In Sucre, the legal capital, which had one of the highest percentages of previous vaccinations, 93.1 percent, only 32.5 percent were found to be vaccinated in the 0-4 age group. In other provinces fewer persons have been vaccinated during infancy and childhood.

The lack of vaccination during infancy and childhood is reflected by the high proportion of the smallpox deaths which are reported in the 0-4 age group. In a recent sample, 95 of 136 consecutive deaths reported were in this age group.

The low percentage of vaccinations, particularly during early childhood, is complicated by the poor quality of vaccinations in the past, largely attributable to the use of glycerinated vaccine without adequate refrigeration facilities. A potent glycerinated vaccine has been successfully produced and applied in Sucre, but this vaccine has not produced reliable results in other parts of the country, as a result of difficulties in maintaining the potency of the glycerinated vaccine. A sample of 463 individuals from a highland province with a temperate

vaccination with type of take of each person in the samples.

The data of the vaccinators and inspectors were routinely tabulated to provide a variety of information including the number vaccinated by month, province, and vaccinator; average number vaccinated per man-day; percentage vaccinated in the campaign; percentage pockmarked by age group and province; percentage with prior vaccination; and percentage of primary takes by vaccinator and lot of vaccine. In addition, tables and maps were maintained for the cases and deaths reported.

Public Information

In the rural areas advance notification of the day of vaccination was given, and at that time the cooperation of the community leaders was obtained. Prior to and during the vaccinations loudspeakers were employed to arouse and inform the public. Possibly of greatest importance was the personal contact of the vaccinator with the individual at the time of vaccination. Everyone vaccinated was considered a potential health educator who could inform family, friends, and neighbors of the harmless but important procedure.

Additional means of informing the public in urban areas included newspapers, radio, pamphlets, and posters. In epidemic situations in two of the largest cities the public cooperated with a more or less spontaneous boycott of those not vaccinated. When the majority of the population had been vaccinated, permission was obtained from the officials of certain public facilities to announce that no one unvaccinated would receive service, effective the following week. Immediately, bus drivers, elevator operators, and most everyone who had taken the trouble to get vaccinated spontaneously supported the boycott. Instead of creating bad feelings, it led to a new form of salute, the raised little finger. The epidemics were abruptly terminated.

Operations

The operations of the vaccination campaign were outlined in specific itineraries for the vaccinators covering periods of about 25 days, including Sundays and holidays, and followed by commensurate days of compensatory leave

when preparations were made for the next itinerary. The vaccinators received individual assignments of specific areas to facilitate the evaluation of the quantity and quality of work. To maintain discipline and aid morale, whenever possible the teams of four vaccinators were given assignments sufficiently close together to permit them to share eating facilities and billeting.

Vaccinations were performed house to house and, when appropriate, were followed by a vaccination session at a temporary center for those who had been missed in the house-to-house vaccinations. Everyone was vaccinated, regardless of age, sex, or previous history of vaccination and smallpox. Those less than 4 weeks old, the acutely ill, and those with eczema were the only exceptions.

The teams proceeded along the main or secondary roads and the rivers and their branches, reaching on foot population concentrations up to 20 kilometers distant from road or river. In instances of reported outbreaks, the teams rented mules and traveled up to 100 kilometers distance from the roads.

Evaluation and Results

With the vaccination of 2,432,186 persons, about three-fourths of the estimated population of Bolivia, the attack phase of the campaign was completed on schedule by the end of 1958.

In the target areas samples totaling 42,075, widely distributed in time and place, showed 91 percent of the population had been vaccinated. The high percentage vaccinated is attributed to the house-to-house visits, followed by a vaccination session at a temporary center, and the use of loudspeakers to attract the people.

The inspection of primary vaccinations of 3,662 infants in samples, widely distributed in time and place, yielded 96.3 percent primary takes.

An average of 210 vaccinations were performed per man-day, excluding the performance in major cities from the calculation. This high average is attributed to advance planning of itineraries, simplicity of the vaccination technique, and paucity of recording required of the vaccinator, permitting exclusive

Methods first developed and successfully applied in Iran were refined and reapplied in Bolivia (2). The campaign was conducted by the Servicio Cooperativo Interamericano de Salud Pública under the auspices of the Ministry of Public Health of Bolivia and the International Cooperation Administration of the United States.

We hoped that approximately 2.5 million of the estimated 3.3 million people of Bolivia in areas with incidence of smallpox or with relative density of population would be vaccinated during the attack phase of the campaign in 1958.

Personnel and Equipment

During the attack phase the smallpox vaccination service of the Servicio, full strength, consisted of 11 teams of vaccinators and supervisory and supportive personnel, a total of 88 persons. Each team of four vaccinators was headed by a team leader who was responsible for quantity and quality of the vaccinations, discipline of the vaccinators, and maintenance of equipment. A physician and two inspectors were assigned to direct and inspect the operations of each of the five teams. A director of the service, an administrative assistant, 17 drivers, and 3 boatmen completed the organization. In addition, the vaccination service had the full support of the administration, health education, and statistics divisions of SCISP, as well as substantial support from other agencies and the public.

Each vaccinator carried a portable vaccination kit which contained all necessary materials for vaccination house to house. The kit included disposable sterile pins, lyophilized vaccine, diluent (50 percent glycerine), and an indelible dye (10 percent silver nitrate).

The motorized teams, inspectors, and physicians were provided with four-wheel drive vehicles equipped with winches and loudspeakers. Three launches powered by 12-hp. outboard motors transported a fluvial team.

The teams were also supplied with portable battery-operated loudspeakers. The staff received two sets of uniforms and boots. Adequate campaign equipment and supplementary rations were issued.

Vaccination Techniques

Only lyophilized vaccine was used in the campaign. The vaccine was supplied by the Institut de Vaccine, Paris, and the Instituto Nacional de Salud Pública, Lima. At no time was the vaccine refrigerated. Some of the vaccine had been stored for as long as 1 year prior to use. Routinely, the potency of the vaccine was retested prior to issuance. The minimal standard for potency required confluency at 1:1,000 dilution with the method of Force and Leak; all lots from Lima and Paris produced confluency at greater dilutions.

The vaccine was reconstituted with a 50 percent solution of glycerine and distilled water by the team leader in the field. Any reconstituted vaccine remaining unused at the end of the day was discarded.

The vaccination procedure was simplified by eliminating the prior application of alcohol or other virucide and by using a sterile, disposable pin for each inoculation. A drop of vaccine was placed over the insertion of the deltoid of the left arm and a single scratch of about 5 mm. in length was made through the drop without drawing blood.

Using the single scratch, which provides visible evidence of vaccination, facilitated uniformity of technique. Consequently, standards could be maintained. The little finger of the vaccinee's left hand was dipped in indelible ink to expedite subsequent inspection of the quantity and quality of the vaccinations. No vaccination certificates were issued, and the vaccinators kept no records other than noting in an itinerary the number of vaccinations and the lot number of the vaccine.

Inspection

The inspectors followed the vaccinators, reading the takes on the ninth day and checking the work of a different vaccinator each day. With 1 inspector for every 8 to 12 vaccinators, the work of every man was reviewed at least once every 2 weeks. The samples inspected consisted of a sufficient number of households to obtain, whenever possible, a total of at least 100 individuals in each locality or subdivision covered by a vaccinator during 1 day. The inspectors recorded the name, age, evidence of previous smallpox, and previous and current

Smallpox has been eliminated from North and Central America. In 1958 smallpox eradication programs, assisted by the Pan American Sanitary Bureau, were being undertaken in eight American countries. Intensification of efforts in three countries with residual foci would rapidly eliminate smallpox from the Western Hemisphere.

Endemic smallpox has been banished from Europe, U.S.S.R., Australia, and certain areas of Africa. However, the Eastern Hemisphere still contains major endemic foci. Asian countries provide about four-fifths of the smallpox cases reported worldwide and a major proportion of exportations of smallpox to other countries (4). The African Continent contains the second most important focus.

The establishment of the priority for smallpox control and, likewise for eradication, involves consideration of the relative importance of the disease in the light of mortality, morbidity, and sequelae, and cannot be limited to the magnitude of the problem remaining, with existing control efforts being taken for granted. Rather, future as well as current action is justified by the potential of smallpox in the hypothetical absence of existing control efforts.

Smallpox is one of the most contagious diseases. There is no specific treatment. Prior to the advent of vaccination, susceptibility was universal, and almost all persons were attacked. Those who recovered from the disease were disfigured, if not blind. Fatal in one in every three or four cases, smallpox depopulated cities and nations. During an epidemic in Iceland in 1707 smallpox killed 36 percent of the total population in 1 year.

Despite the prevailing policies of control, smallpox is still only too prevalent in many areas of the globe. With reporting very incomplete, an annual average of 178,000 cases was notified to WHO in the 5 years 1951-55 (4). This situation requires either an extension of complex and continuing systems of control to all areas of the globe or short-term campaigns so placed and timed as to lead to the worldwide eradication of smallpox.

A policy of eradication is favored by the relative amenability of smallpox to eradication. From the point of view of the individual, vaccination is a specific and reliable protection

against smallpox, involving minimal inconvenience. From the point of view of health authorities, no other preventive measure can be extended with such ease, economy, and effect.

Vaccination is unquestionably the most effective of all preventive procedures, having been credited with saving as many lives as all the rest of preventive and curative medicine since Jenner's discovery in the 18th century (5). Now that lyophilized vaccine exists, only the ultimate utility of a thermostabile vaccine remains to be exploited. Full utilization of the vaccine would break the chain of infectious cases on which the smallpox virus depends for its continued existence, carrying disease prevention to a logical conclusion—eradication. Thus smallpox is an anachronism. Thomas Jefferson, an early active supporter of vaccination, wrote to Jenner in 1806, "future nations will know by history only, that the loathsome smallpox has existed."

There is a growing awareness of the national obligation to eliminate endemic smallpox in recognition of the right of other countries to be protected against the reinfection of areas freed of smallpox. Thus the intensified national efforts represent contributions to international health. If it is accepted that the whole world benefits from national campaigns which are an integral part of worldwide eradication of smallpox and that the costs of the campaigns exceed by far the costs of technical assistance, then the more prosperous countries, already freed of smallpox, cannot expect to share the benefits without sharing the cost of the national operations. The alternative is for the countries with endemic smallpox, large populations, and little surplus for investment to assume the major financial burden of eradication.

Mass vaccinations probably can be limited to the endemic foci. Costs, globally distributed, should not be a major obstacle when total costs of vaccination by mobile teams in sparsely populated areas are in the order of 5 cents per capita.

The Eleventh World Health Assembly noted that the funds devoted to smallpox control and vaccination throughout the world exceed those necessary to eradicate sources of the infection. Moreover, eradication represents a capital investment that makes the recurrent costs of con-

dedication to vaccination. The indelible dye not only saved time but provided a more reliable record for inspection purposes than histories or vaccination certificates.

As a result of the high average of vaccinations per man-day, the costs of the campaign, including personnel, vehicle, equipment, vaccine, and all other expenses, were held to 5 cents per vaccination.

The dramatic reduction in reports of smallpox best illustrates the results of the attack phase. In 1957 Bolivia suffered the highest attack rate for smallpox in the Americas. By the end of 1958 Bolivia enjoyed one of the highest levels of immunity and experienced an apparent cessation of transmission (table 3). Since November 1958, no smallpox has been reported in the Weekly Epidemiological Reports of the Pan American Sanitary Bureau.

The efficiency of the methods and the efficacy of the lyophilized vaccine are confirmed.

Consolidation and Followup

During the consolidation phase, to be completed by four mobile teams in 1959, vaccinations will be extended to those in sparsely populated and rather inaccessible areas not reached during the attack phase.

With the completion of this phase the Servicio will have discharged the mandate of the bilateral project agreement. Unless the agreement is amended and extended, maintenance of vigilance and a high level of immunity will be a function of the Ministry of Public Health.

Now that smallpox is no longer endemic in Bolivia the occurrence of a single case must be considered as an emergency and treated accordingly. The prevention of rapid recurrence of widespread infection will require the

maintenance of a complete and efficient system of defense including a network of centers and mobile teams for vaccination and revaccination, early recognition of any residual focus and imported cases, reporting, laboratory confirmation, casefinding, and contact and ring vaccination in remote rural as well as urban areas. Arrangements for the continued importation or the national production and testing of lyophilized vaccine will also be necessary.

The high level of vigilance and immunity will have to be maintained even after the completion of campaigns in other South American nations removes the source of this disease from the American Hemisphere until global eradication is achieved.

Global Eradication

Abrupt elimination of one of the principal foci in the American Hemisphere by a mass campaign in the face of a unique combination of factors adverse to control through routine services illustrates the feasibility of smallpox eradication by a systematic attack on the sources of the disease.

The campaign in Bolivia, assisted by the International Cooperation Administration, formed an integral part of a hemispheric campaign. In 1950 the governing bodies of the Pan American Sanitary Organization recommended that the member governments undertake systematic programs of smallpox vaccination and revaccination in their respective territories with the aim of eliminating the disease from all parts of the Western Hemisphere. The Pan American Sanitary Bureau drew up a program designed to stimulate the efforts of the Americas (3).

the fatherless family

PREVENTION of serious family disturbances, rather than their treatment, was the keynote of the biennial meeting of the Family Service Association of America, April 1-3, 1959, in Washington, D.C.

A feature of this new emphasis is family life education. The delegates, representing 286 family counseling agencies, were told that large numbers of people in community groups are being introduced to the basic patterns of human behavior through lectures and demonstrations. Areas of focus in this education program are largely determined by participants to heighten the material's usefulness.

Other papers discussed and analyzed "rejected" fathers in the contemporary mother-dominated family, and analyzed the functional position of the American family, as well as mother-child relations and special problems of the aging.

A topic ranking high among the most relevant and pressing was the fatherless family, on which the following summarizes two approaches.

The Imbalance Factor

Citing the country's large number of broken families, Ruth J. Peterson, district director of the Family Service of Philadelphia, observed that social pressures are no longer sufficient to stabilize marriage; it must be done through inward cohesion. In the fatherless family, that

cohesion is disrupted by an imbalance in the potential for fulfilling each member's needs. The degree of imbalance hinges on the cause of the father's absence, the mother's emotional health, and the level of emotional maturity already reached by each child.

Reviewing recurrent patterns of disturbance, Peterson first turned to those fatherless through an act of fate. Normally in such a family, she explained, each member adjusts to loss of the father, through an individual sense of identity. None feels permanently destroyed, nor does he feel to be the destroyer. When healing is blocked, as in most cases referred to social agencies, the first task is to analyze the reactions to crisis and to sift for emotional factors. Significant are the emotional currents between the parents at the time of death and the way the mother is meeting her own dependency needs. For example, out of guilt over her hostility to the father for leaving her, is she tied to following his instructions? Does she gratify her needs through her children, thus hindering their further emancipation? Is there psychosexual regression to the preoedipal period, bringing rivalry with the children.

After loss of the father, the children's attachment to the mother heightens, often with strong ambivalence. On the whole, the children's reactions reflect the mother's demands and the level each had reached in resolving the oedipal conflict. Peterson offered the following illustration. Mrs. W., whose husband died

trol redundant. The Assembly recommended to all governments that the population be vaccinated where principal endemic foci exist and subsequently where the disease persists. The Assembly also recommended that all countries in which smallpox vaccination is compulsory continue to give smallpox vaccinations during the eradication of this disease throughout the world.

At the Twelfth World Health Assembly in May 1959 the arguments in favor of smallpox eradication were reiterated, and the urgency of worldwide eradication was emphasized. It remains for the governments to initiate timely cooperative action.

H. Trendley Dean Retires

Dr. H. Trendley Dean retired July 19, 1959, as secretary of the Council on Dental Research of the American Dental Association.

His pioneer research and continuing study on the effects of adding fluoride to city water supplies established Dr. Dean as an international authority.

One measure of his contribution is that a population of 35.6 million persons in 1,800 cities throughout the United States use public water supplies to which fluoride has been added to inhibit dental caries.

Before joining the association in 1953, Dr. Dean was associated for more than 30 years with the Public Health Service.

Dr. Dean's research into fluoridation dates back to the 1930's. During a study of mottling of teeth in communities where there was a high concentration of fluorides in the water, Dr. Dean and his associates observed also that the tooth enamel was unusually well preserved.

This observation led to a long-term study

to determine the level that would avoid staining of the enamel and still check tooth decay.

In 1942, following a study of 21 cities in which more than 7,000 children were examined, Dr. Dean and his fellow scientists concluded that: "Where the fluoride level is about one part per million, there are about 60 percent fewer decayed teeth than in nonfluoride areas."

In 1945, Grand Rapids, Mich., became the first city to add fluorides to its water supply. The measure has been employed since then in communities in Brazil, Chile, Colombia, England, Germany, Holland, Japan, Sweden, and elsewhere.

Dr. Dean expects to continue his efforts in support of fluoridation. He feels more strongly than ever that: "The time is past when fluoridation could be considered a 'progressive' step. It is an integral and routine part of any complete public health program. Cities thus far which have failed to adopt the measure are simply failing in their responsibility to the public."

hurt and rejected underneath. She married a successful businessman, but her feelings of worthlessness led to her uncooperativeness, accusations of belittling her, and finally her leaving. Life then centered in her son whom she pushed toward excellence and controlled through her demands. Threatened by the trauma of desertion, she sought help for herself and her son.

Parents Unwed

Most unmarried mothers, Peterson remarked, have passive masochistic tendencies intensified by guilt feelings which are gratified by illegitimate motherhood. The majority have had much emotional deprivation; many are themselves illegitimate and have been rejected. The result is a feeling of worthlessness and little capacity for objective relationships.

The children may be used to vent hostility to the grandmother, through forcing her to care for them, or as a source of gratification, or to force the father into meeting dependency needs. The children feel stigmatized by lack of a father, for which they blame the mother. A daughter may some day air her hostility by becoming another unwed mother. Boys may have strong homosexual tendencies.

Peterson pointed out that the direct diagnosis and treatment of children's emotional problems, developed during the past decade, put family agencies in a preventive as well as treatment role in relation to the community's fatherless families. In her opinion, until living standards are decent for the minority groups providing most of these mothers, there is no base for developing inherent feelings of self-worth. Another need is an adequate number of trained social workers in public agencies for individual counseling, with financial aid as a basic service. Meanwhile, family agencies can offer a realistic diagnostic and evaluation service as well as supportive help in the use of community facilities for positive sources of identification, such as child day care, leisure time activities, or treatment placement.

Pointing to the growing punitive attitude of the tax-paying public toward families with children born out of wedlock, sometimes expressed in tighter eligibility requirements for

aid, Peterson warned that such efforts to force conformity with social standards ignore the original emotional conflicts which produced the illegitimacy.

Aid to Dependent Children

Legislation which penalizes segments of the indigent population underscores the need for telling people more about the goals of public assistance, especially aid to dependent children, declared Mary Brenz, assistant executive director for social services, Philadelphia County Board of Assistance.

Close to 2 million fatherless children receive aid to dependent children, she reported. Commonly, they are described as born to shiftless women, mostly unmarried, in filthy homes, and growing up into delinquents to retrace the mother's behavior patterns. Evidence to the contrary, she said, is shown in findings of a current, representative study in Philadelphia. The meager aid is generally a stopgap in the child's early years. Also, there is a high degree of social breakdown. In a similar 1953 study, only 3 percent of children covered in this aid program were in neglect cases, and 2 percent in delinquency hearings, not above the city's average.

Brenz pointed to built-in features of the program that bring in many more families broken by discord or lack of planning than by an act of God. A widow's children, for example, are blanketed under social insurance. Cases of desertion predominate. Usually those who plan to break the marriage legally also plan for the future.

In desertions, most frequent in large cities with their opportunities for anonymity, the father may reappear and disappear, making any plans haphazard. This also characterizes the lives of unwed mothers.

Brenz's experience has shown that status is a pervasive ingredient of social breakdown which ends in desertion and illegitimacy. The latter occurs most often among women with little economic or social stake.

She also pointed out that by custom unwed Negro girls tend to keep their babies. Further alliances are more likely to result in more illegitimate children than with those who give up their babies and plan normal lives.

after a 2-year illness, was still hostile to her mother for a lifetime of demands, including care of siblings. Feeling little worth as a woman, she resented her husband's domination and his failure to share child discipline. Following treatment which allowed venting her hostility, she supported treatment of her daughter, who had withdrawn from her friends in what was diagnosed as anxiety hysteria. The girl projected onto all, the "duplicitous" of her father who had died when she was "unprepared." By airing her oedipal fantasies and working through her anger, mother-daughter relations gradually improved.

Sometimes early help to the mother might have resolved the conflicts of both mother and children, continued Peterson, citing the maladjustment of Mrs. Y. and Andre, which stemmed from this mother's consistent refusal to reveal the father's death to her son. In war-torn Europe, Mrs. Y.'s mother and brother had been murdered shortly before her marriage to Mr. Y., who she felt replaced both. On Mr. Y.'s urging, she consented to come to this country, to avoid responsibility for denying 3-year-old Andre the benefits of growing up here. After loss of her husband 6 months later, she refused an opportunity for higher income in her native land, and only when Andre reached 8, told him of Mr. Y.'s death. Irregular behavior at school followed, leading to casework interviews. They revealed Andre's retarded ego development and hostility to his mother caused anxiety resulting in a mixed neurosis with anxiety hysteria and obsessive compulsive features.

Often disturbances emerge first during adolescence, Peterson remarked, when withdrawal sometimes alternates with aggressive acts. School work suffers; previous defenses no longer suffice; and the adolescent's greatest fear is his loss of self-control. All this may stimulate the mother's unconscious conflicts, her resulting pressure aggravating further acting out which confirms the adolescent's feeling of worthlessness.

Homes Broken Voluntarily

Peterson pointed out that families with the father absent through separation, desertion, or divorce far outnumber other fatherless families

on social agency registers. Here may be the added conflict around reunion and the responsibility for breaking up the home. Most often the mother has been left.

Success in adjustment hinges on the duration, degree, and openness of the marital conflict before the break. Most of these mothers, in Peterson's opinion, lacked the maturity and self-awareness to choose suitable partners, to realistically assess each partner's ability to meet the other's demands, and to understand and adjust to parenthood. They also commonly lacked certainty about themselves in the passive feminine role. Peterson stressed ascertaining at what psychosexual stage growth had been retarded. If in the preoedipal period, for example, receptive needs may be insatiable. Overidentification with the children and identification of one child with the father are also possible.

Diagnostically, it is vital to know the mother's relationship with her parents, asserted Peterson, as in the case of Mrs. G. Her hostility to parental authority had found expression in her marriage to Mr. G., who was illiterate and physically cruel. Her sadomasochistic disorder kept her silent about her husband's incestuous relations with the daughter and abuse of the other children, until known outside. On release from prison, Mr. G. was restricted to another part of the State; the daughter, who had identified with the mother, was helped toward a better reality adjustment; and the oldest boy, with irreversibly defective psychosexual development, was encouraged to broaden his life through wholesome activities. The children's treatment allowed Mrs. G. wider outside interests.

Frequently, stated Peterson, even though there are realistic reasons for ending a marriage, the wife's feeling is one of rejection and failure, the depth of these feelings gauging how much she accepts the feminine role. Symptoms may be depression and projection of blame on the partner. An example was Mrs. N. who developed anxiety with somatization over her adolescent son's visits with the father. Features of her childhood were insecurity, a strict stepmother at age 5, and loneliness during adolescence. Feeling incompetent as a woman, she entered business, was successful, but remained

The Federal Budget Process

RALPH BAHN, M.C.S., C.P.A.

MANY MEDICAL PEOPLE in administrative positions consider budgets and the budget process a form of mystic symbolism and ritual, with its own priesthood called budget officers. Many laymen react the same way to the medical profession. From a layman's viewpoint, the doctor asks some questions, grunts a couple of times, putters around with the patient, sometimes using awesome gadgets, and pontificates a diagnosis. In both situations, lack of understanding of the purposes and specific processes creates uncertainties and possibly fear.

It is hoped that this report on the budget process, by describing the process and the logic behind it, will dispel some of the mysticism.

Budgeting is closely related to financial planning and management, although the term may properly be used in a more general sense of planning. All of us, consciously or unconsciously, do a great deal of budgeting. For example, a family's standard of living is budgeted against its financial resources. The corner storekeeper, formally or informally, budgets his cash outgo to coincide with his estimate of cash income. Larger organizations use similar but more sophisticated techniques to arrive at the same result.

By their very nature, public health activities are financed almost entirely by governmental bodies (Federal, State, county, municipal, and other political subdivisions). Administrators,

or prospective administrators of public health programs, find that budgeting plays an increasingly important role in their professional careers.

There are about 100,000 units of government in the United States (1), including the United States itself, States, counties, incorporated places, towns and townships, and school districts. Many of them have slightly different forms of government. Since budgetary management is intimately related to the political division of authority between the executive and the legislature, in accordance with charters and precedents, the budgetary processes of the various units differ, and no one system can completely fit them all. However, although terminology and the names of the various executive and legislative groups which have roles in budgetary management may differ, certain basic budgetary processes are used by the majority of these units.

The large and varied financial programs of the U.S. Government affect all citizens. Because of the intense interest in Federal programs by many individuals and groups, this report will use the terminology and procedures of the U.S. Government as an example. Because of its vast size and scope, however, this process may be more complex than that of other units of government.

Definition of a Budget

In a nongovernmental organization, a budget is defined as a financial plan of program operation for a specific period of time, expressing the use of men, other services, and matériel in a common denominator: money. In governmental bodies, it means the same thing with the

Mr. Bahn is financial management officer of the Bureau of Medical Services, Public Health Service. This article is based on lectures he gave at the Graduate School of Hygiene and Public Health of Johns Hopkins University in 1958 and 1959.

Pinpointing some unresolved questions in casework for the aid to dependent children program, Brenz described the cycle of inherently difficult cases and heavy caseloads, the high turnover of caseworkers, and insufficient rapport between clients and caseworkers. Eligibility terms are often harsh and grants barely provide subsistence.

Broadened Approaches

Brenz pointed out that public agencies, unlike private services, cannot limit their intake, or dispose of cases as untreatable. Many cases covered by aid to dependent children had been abandoned by the highly skilled workers of private agencies. Seeking solutions, Philadelphia has limited caseloads for some workers and used authority in working with public assistance families. Referring to Family Services Units of England, which handles only "hopeless" cases, Brenz outlined a personal approach designed to guide the client. To win the client's confidence, the caseworker may tidy house or scrub the floors.

At this point, Brenz warned against the inadequately trained caseworker translating her own biases unconsciously into standards for

clients. "We already have almost the power of life and death over our clients in that we represent their bread and butter," she said. For effective help to fatherless families on public assistance, she recommended:

- Grants adequate for living rather than for bare subsistence, so that these families really be given "a chance to try."

- Broader information programs about aid to dependent children to help dissolve punitive attitudes into understanding and willingness to support adequate grants and a sufficient and adequately paid staff.

- Guidance from the Department of Health, Education, and Welfare on the desirable pattern and scope of services for public assistance agencies. One area would be the acceptable minimum grant and constituent items.

- Wider cooperation of other social agencies, such as child guidance clinics.

Partnership with other community resources, she concluded, will put the needs of fatherless families into sharper focus.

The papers by Miss Peterson and Miss Brenz appear in full in a pamphlet published by the Family Service Association of America, 215 Fourth Avenue, New York, N.Y.

Study of Medical Care for the Indigent

Means of assuring adequate medical care for an estimated 6 million persons on public relief rolls may be indicated in a study of 20,000 individual welfare records at the University of Michigan School of Public Health. Supported by the American Public Welfare Association, the project began in 1957.

According to Dr. Solomon J. Axelrod, the school's professor of public health economics and principal investigator of the project, "The problem of providing medical care for these people is immensely complex. Many of them were forced onto relief in the first place because they were sick."

During this initial phase of the project, the sample data have been collected from welfare departments in Connecticut, Illinois, Maryland, and Rhode Island. Research is now

focused on the amount and kind of medical care given recipients of old age assistance.

"More and more of the aged are depending on old age assistance for medical care, even while drawing social security payments," Axelrod reported, because these payments "in many cases do not provide enough money for medical attention."

Other objectives of the project are the clarification of certain administrative problems, such as the larger proportion of funds spent on prescribed drugs than on physicians' services in some of the medical care programs for recipients of old age assistance and the question of long-term hospitalization for the aged. Often the elderly have long hospitalizations simply because of the lack of another place to stay, Axelrod remarked.

marized to obtain a total cost for operating the department or organization. A summary of these appropriations provides an organizational budget classification.

Performance or program budget. Today much emphasis is placed on what is described as a performance, or program, budget, in contrast to budgets based solely either on objects of expenditure or organizational units. The performance, or program, budget as defined by the Hoover Commission is a "budget based on function, activities, and projects . . . which would focus attention on the general character and relative importance of the work to be done, or upon the service to be rendered, rather than on the things to be acquired, such as personal services, supplies, equipment, and so on. . . . The all-important thing in budgeting is the work or the service to be accomplished and what the work or service will cost." Table 2 is a sample of the summary program and financing schedule. This schedule is still supported by the object class distribution listed in table 1.

Cost-type budget. Cost-type budgets are based on data geared to accrual accounting. Accrual accounting, which is generally used in private businesses, bases its costs on actual consumption of goods and services rather than on obligations. Table 3 converts table 2 into a cost-type budget. This is done by merely accruing inventories of goods and services carried

over from year to year. In table 3, in the column headed 19-6, obligations of \$715,900 are adjusted to a cost of \$678,519 because \$37,381 worth of supplies and equipment purchased out of 19-6 monies were not used. In column 19-7, obligations of \$698,400 are converted to costs of \$711,300 resulting from greater use of supplies and equipment in 19-7 than were purchased in 19-7. (Public Law 863, enacted August 1, 1956, provides that Government appropriation requests shall be developed from cost-based budgets in such manner and at such time as may be determined by the President.)

Historical Background

In order to understand reasons for current budget processes, it is necessary to review the conditions and situation which led to budget reform in the United States.

From the establishment of the U.S. Government in 1776 to as late as 1921, "no provision existed . . . for preparation by an agency of a single, consolidated statement of prospective revenues and of the estimated expenditure needs of Government—so prepared as to reveal the relations between the two and to furnish an intelligent guide to Congress of the policies that should be adopted by it in respect to increase or decrease of taxation, the incurring or eliminating of debt and the voting of funds for the conduct of the U.S. Government" (3).

additional provision that when a budget is formally approved, certain controlling factors of it become law, and the law is the controlling instrument over financial operations of that governmental body.

The budget is a means of orderly financing which is necessitated by the huge financial programs of modern governments. "In democratic governments it permits the people, through their representatives, to retain control of public finance" (2).

The budget document is essentially an estimate of future governmental income, expenditures, and fiscal conditions. The document also customarily includes a report on the finances of the previous and present fiscal periods. For example, the U.S. budget for 1960 shows actual data for fiscal year 1958, estimated data for fiscal year 1959, and estimated income and expenditures for the budget year, 1960.

The budget process can be defined as the ac-

tivities in the preparation, legislation, execution, and control of the budget.

Types of Budgets

Object classification budget. Many years ago budgets were almost exclusively based on an object classification. This type of budget listed in varying detail the positions to be filled and the specific items of supplies and equipment to be purchased. Sometimes there would be one appropriation for personal services and another for the other object costs of a given organization. Table 1 is a sample of this type of summary budget schedule. In addition to the data shown, these budgets were supported by detailed lists of positions to be filled.

Organizational budget classification. Because of the large numbers of appropriations which can be involved in support of a given department or organization, the appropriations are placed together in the budget and sum-

ative prosperity and the fact that Federal taxes were almost entirely indirect and scarcely felt by the individual taxpayer.

The rapid development in the scope and amount of governmental expenditures, with an increasing burden of taxation on individuals, focused popular attention on the problem of obtaining more efficient administration of governmental units and led to the adoption of modern budget procedures by the Federal, State, and local governments.

Budget Reforms

In 1921 passage of the Budget and Accounting Act led to a reorganization of Federal financial operations.

The most important change brought about by this act was to place upon the President direct and complete responsibility for preparing and submitting to the legislature, at the beginning of its regular session, a budget which would represent his administration's work and financial programs and his recommendation for financing them. It also prohibited any other employee of the executive department from submitting any other budget recommendations unless requested to do so by a member of Congress. By implication, this also prohibited any executive department employee from submitting any general legislative recommendations which could lead to the need for new funds. The act also provided the President with staff to assist him in handling the financial management of the government. This organization is called the Bureau of the Budget. (Originally established in the Treasury Department, it was transferred to the Executive Office of the President in 1939.)

The 1921 act also authorized an audit staff, under control of and reporting to the legislature. This staff, called the General Accounting Office, reviews the execution of the administration's work and financial programs. Executive department officials, seeking clarification of legislative intent in connection with ambiguous legislative language, may obtain legal opinions from the General Accounting Office to avoid error or criticism.

Concurrently with the passage of the Budget and Accounting Act, both the House of Repre-

sentatives and the Senate amended their rules of procedure to require clearance of all appropriation requests through a single committee on appropriations in each House. In addition, they agreed that the committee on appropriations shall not have power to report bills containing general legislation and that a separate committee would handle all revenue bills.

Subsequent amendments to the Budget and Accounting Act of 1921 have tended to increase the authority of the Bureau of the Budget and the President over governmental fiscal operations.

This general pattern of reform adopted by the United States has been adopted also by many State and local governments.

The Budget Process

The Federal budget process is necessarily continuous. With regard to annual appropriations, the process requires constant review of the current year's program and review and cleanup of previous years' activities. Concurrently with these reviews, plans must be made for 1 or 2 years in the future. For example, agencies are operating under fiscal year 1960 funds, liquidating obligated balances of prior years, preparing 1961 estimates for processing through the Bureau of the Budget and the Congress, and developing plans for the 1962 preliminary estimates.

Omitting the overlapping in the various budgets, a typical budget calendar is outlined on p. 788 and the cycle for a single annual budget is reviewed below. If the preliminary estimates were excluded and the names of participating organizations and possibly the time intervals were changed, the calendar would have many similarities to State and local budgetary calendars and processes.

Preliminary Estimates

Each spring, the Bureau of the Budget makes a fresh review of the budget outlook for the Government as a whole. This review is used as a basis for determining policies to be recommended to the President for use by the agencies in the preparation of their formal budgets. To assist in this review each large agency develops a preliminary estimate, which is a broad pro-

Estimates were prepared by the various departments and submitted to the Treasurer of the United States. The Treasurer, in turn, passed them on to the Congress without review as to need, duplication of services, or available revenue. The President had little or no function in the budget process.

"In the House of Representatives, the estimates were reviewed by eight distinct committees, each acting independently of the others, and no one having overall responsibility for relating expenditures to available resources and prospective income" (3). Sometimes different committees reviewed separate portions of a department's estimates with the result that the de-

partment could shop the "easier" committee for appropriations.

The system for handling finance measures in the Senate repeated all the mistakes in the House and added a few more.

"In addition, conference committees, reconciling appropriations bills between the versions approved by the two legislative bodies, violated their own rules of procedures by changing items beyond the areas of disagreement" (3).

Similar chaos existed in most State, county, and municipal governments up to the early 1900's.

This system of fiscal anarchy was tolerated in the Federal Government because of its rel-

Calendar for 1960 Budget Estimates—Continued

February 1959

House subcommittee on appropriations holds hearings on estimates. Witnesses from divisions, bureaus, Service, and Department defend them.

March 1959

House Appropriations Committee reports out recommendations. House acts on recommendations.

April 1959

Senate subcommittee on appropriations holds hearings.

May 1959

Senate Appropriations Committee reports out bill. Senate passes bill.

June 1959

Conference committee from both Houses iron out differences, if any. President signs bill, enacting bill into law.

Apportionment

June 1959

Divisions request Budget Bureau apportionment of funds appropriated.

Allotment

June 1959

Divisions notify field stations of annual allocation and issue allotments of first quarter funds, in accordance with approved apportionments.

September 1959

Divisions issue second quarter allotments.

December 1959

Divisions issue third quarter allotments.

March 1960

Divisions issue fourth quarter allotments.

Reporting

Monthly, fiscal year 1960

(July 1959–June 1960)

Each echelon reviews monthly reports on obligations and expenditures. Compares with allotments and apportionments.

Cleanup of Funds Not Available for Obligation

July 1960–June 1962

Public Health Service closes out fiscal year 1960 accounts.

views the estimates of its subordinate levels. This review (a) checks compliance with policies, (b) eliminates duplication, (c) adjusts the various estimates for balance within that program level, and (d) recommends estimates to the next higher echelon. In this way, estimates are built like a pyramid for a division, a bureau, a department, and finally the U.S. Government.

Most Federal budget appropriation requests are submitted to the Bureau of the Budget and the Congress only for activities for which basic legislation exists. (Basic legislation is law authorizing the Government to do something new or extending existing authorization to continue something already being done.) This practice, based on precedent established by the President in 1921, serves two purposes; (a) it avoids placing pressure on the executive department to request appropriation of funds for activities, no matter how desirable, not yet approved by the Congress, and (b) it avoids

legislation subject to easy defeat by a "point of order." Basic legislative items appended to an appropriation bill in violation of existing congressional rules may be eliminated by any member of Congress, during the course of debate on the bill, simply by raising a "point of order."

The Bureau of the Budget consolidates the preliminary estimates of the large agencies and adds an informal estimate for the smaller ones to determine total governmental fiscal requirements for proposed agency programs. These requirements are compared with estimates of revenue to provide the budget outlook for the Government as a whole.

The Director of the Budget Bureau meets with the agency heads individually to discuss the agency's budget in relation to the overall fiscal outlook. In these meetings the agency head reviews his organization's operations and summarizes the need for his proposed programs.

Calendar for 1960 Budget Estimates, Bureau of Medical Services, Public Health Service

(Annual Appropriation)

Preliminary Budget Estimates

January 1958

Bureau issues call for 1960 preliminary estimates from divisions. Large divisions request data from field installations.

April 1958

Divisions summarize, review, adjust, and recommend their estimates to Bureau. Bureau summarizes and reviews estimates, and passes on approved Bureau estimates to Surgeon General.

May 1958

Surgeon General summarizes and reviews all Public Health Service estimates, and passes on approved Public Health Service estimates to the Secretary of the Department of Health, Education, and Welfare.

May 1958

Department compiles and reviews all constituent estimates and submits them to Bureau of the Budget.

June 1958

Budget Bureau summarizes all Government estimates, reviews programs, compares costs with estimates of income, and recommends budget policies to President. President approves governmental budget policies and level of operations.

July 1958

Department and Budget Bureau negotiate authorized budget allowance. Sum of all departmental estimates cannot exceed agreed-upon total. Department allocates budget authorization among constituents. Public Health Service, as a constituent, subdivides its allocation among its bureaus and divisions.

Formal Budget Estimate

September 1958

Department submits formal budget estimate to Bureau of the Budget.

November 1958

Budget Bureau "marks-up" formal budget submission and consolidates estimates in the Budget of the United States Government.

November 1958

Divisions prepare congressional budgets based on "marked-up" budget to be published in the Budget of the United States Government for fiscal year ending June 30, 1960.

Legislation

January 1959

President gives budget message to Congress.

gram document outlining the agency's current and future operating and financing programs.

In developing the call for preliminary budget estimates, each echelon of Government outlines its basic policies and assumptions within the framework allowed by higher echelons. For example, a department may list its basic policies and assumptions for the preparation of department estimates. Within this framework, bureaus and divisions may add criteria which do not conflict with the criteria of the higher echelons.

To justify budgetary estimates more fully, many Government agencies obtain participation in formulating the preliminary estimates at the lowest organizational level at which this is feasible.

The call for estimates requires each supervisory level to review existing programs and make decisions on whether or not program emphasis should be modified, based on changes arising from conditions, resources, or accomplishments.

Each supervisory level summarizes and re-

appropriation, a statutory authorization to a government agency to incur obligations (obligate) for not more than a stated sum of money, for specified purposes, often within a stated period of time. Several of the more important types are defined below.

annual appropriation, an authorization available for incurring obligations for 1 year only. Most common type in the Federal Government.

multiple-year appropriation, an authorization for incurring obligations for a definite period of time, but in excess of 1 year. Used for seasonal programs or for nonrecurring programs that do not fit into a fiscal year pattern.

no-year appropriation, an authorization available for obligation until the purpose of the appropriation has been accomplished. Used for such work as construction projects, certain research and development programs, and long-lead procurement programs.

appropriation limitations to accomplish specific objectives may be imposed by the legislature; for example, a limit on the amounts which can be spent for specific purposes or a requirement that a minimum amount be spent for a certain purpose. An appropriation on a lump-sum basis for several pro-

grams gives the agency some discretion in varying the use of the funds among programs, but an appropriation specifying the amounts for each program has the effect of imposing a separate limitation on each item very similar to separate appropriations.

apportionment, distribution of an appropriation into amounts available for specified time periods, activities, functions, projects, objects, or combinations of these. Amounts so apportioned limit obligations to be incurred. Generally, apportionments are used to limit obligations for specific time intervals, usually quarters, over the appropriation period in order to prevent organizations from running out of obligational authority before the end of the fiscal period and thereby incurring a deficiency.

allotment, an authorization by head of the agency or his designee to incur obligations within a specified amount pursuant to an appropriation and apportionment. It is a method of subdividing apportioned funds.

obligation results when goods and services are ordered. When they are received, the obligation becomes a legal liability to pay for their purchase.

encumbrance or commitment, the current reservation of funds for a specific future payment.

department may appeal differences on significant items to the President. Subsequently, determinations by the Director of the Budget Bureau and the President are communicated to the agency.

In December, approved budget estimates for all the agencies are brought together and made part of the President's budget document. This is delivered to the Congress together with the annual budget message during the first 15 days of the session beginning in January.

All budget estimates are administratively confidential until released by the President in his budget message to the Congress.

Other Estimates

Amended, supplemental, or deficiency estimates may be submitted to the Congress with the approval of the President (a) to finance programs resulting from enactment of new leg-

islation, after the regular budget has been submitted to the Congress or (b) to meet emergencies or conditions under existing legislation not anticipated when the original budget was prepared.

Legislation

Constitutionally, the House of Representatives originates all revenue-raising bills. The House has uniformly held that the section of the Constitution authorizing it to originate revenue bills (art. 1, sec. 3) was intended to cover appropriation bills as well. Although the Senate has at times questioned this claim, it has generally abided by it.

All appropriation requests are submitted to the House Committee on Appropriations (except that after passage of the appropriation bill by the House certain urgent items may be submitted directly to the Senate Committee

After carefully weighing overall budget objectives against the policies' effect on the programs and responsibilities of each of the larger agencies, the Director of the Budget Bureau recommends to the President the policies to be followed in the preparation of the formal budget. Proposed budget policies and their impact on agency programs are discussed by the President with members of his cabinet.

The President determines the policies to be followed by the agencies and the overall budget objectives of the Federal Government. The objectives may be, for example, a balanced budget, emphasis on national security, and increased international aid. On the basis of these policies and objectives, the President determines the level of governmental expenditures desired. If expenditures are planned to exceed revenues, the President proposes additional taxes or an increase in the Federal debt to finance the excess. If revenues are expected to exceed expenditures, the surplus may be applied to reduce the Government debt.

The President's determination on governmental expenditures is made available to the agencies in the form of a budget allowance, which sets the maximum amount that the agency may request in its formal budget for the fiscal year under consideration. The budget allowances are then allocated by the agency to its bureaus and divisions.

As stated previously, the President is responsible for submitting a budget for his work and financial programs. He is not required to recommend appropriations to the full extent of basic authorizations. He may recommend a lesser amount or no funds at all.

In the evolving budget formulation process, the preliminary estimate appears to be assuming more and more importance in determining the programs to be supported. All governmental budget estimates are highly competitive. They are alternate bids for use of a scarce item: the tax dollar. In the competition for use of this item, a budget proposal generally must be approved in the preliminary process if it is to be included in the formal estimate.

Formal Budget

The budget allowances by the Budget Bureau generally require reductions in program plans

proposed in preliminary estimates. When the reasons for the reductions are given or the items to be eliminated are identified, the agency will generally give serious consideration to the Budget Bureau's suggestions. To include items not favored by the Budget Bureau in the formal estimate is to risk having the item eliminated again in the Budget Bureau's review of this estimate and thus lose authorization which might have been allowed for another desirable purpose.

When the bases for the reductions are not identified, the person responsible for the appropriation programs will determine where cuts are to be made. Although the basic budget data for an appropriation may have been developed with full participation of field staffs, the pressure of time in the processing of the formal and congressional estimates may preclude their further participation.

The departments are generally informed of their budget allowances in July, and they are required to submit their formal budgets no later than September 30. These formal estimates must be prepared in accordance with the allowance limitation and the procedures set forth by the Budget Bureau (4). They list in detail how the requested funds will be spent.

In order to point up important requirements that cannot be accommodated within an appropriation allowance, a supplementary, or "B," budget is sometimes submitted with the formal estimate. The "B" budget is evaluated by the Budget Bureau with the formal estimate, and if the Bureau considers it important enough, it will include funds for the item in the appropriation request.

In October or November the Bureau of the Budget holds hearings on the formal estimates. These afford the Bureau another review of an agency's programs some 5 months after submission of the preliminary estimates. At this time the Bureau may make further adjustments in an agency's budget based on current conditions. Budget Bureau examiners question agency officials, and they may ask them for additional evidence to support their estimates or to revise them. The Director of the Budget Bureau and the agency head endeavor to reach substantial agreement, but the secretary of a

past activities in comparison with the budget and for forecasts of future workloads or fund needs. Each echelon performs its own evaluation on its level and scope of the program.

Periodic financial reports (generally monthly) on the status of allotments or suballotments are an important part of this evaluation. They are submitted from each accounting level to the program chief. Generally, only appropriation reports are submitted to the Budget Bureau, but the Bureau may request such data as it deems necessary (6).

In order to permit operating evaluations in relation to the budget, expenditure accounts should be kept on a functional (program) classification basis consistent with the budgetary classification, or they should be capable of being summarized on such a basis without analysis or adjustment.

The process of review is continuous until the period for which the appropriation is available for obligation expires. At that time unobligated balances are no longer available for use and they are withdrawn.

Sometimes the periodic evaluations show a need to shift funds, within one program activity, from one geographical area to another. This kind of shift is ordinarily within the authority of the program chief. However, an indication of a need for shifts between activities may present complications.

If funds have been appropriated on an individual-activity basis within a budget, no changes between activities are possible without legislative approval. When the appropriation is for a lump sum of money covering several activities, program chiefs may obtain minor adjustments among the activities from higher authority as designated by the head of the department without further clearance. Significant shifts of funds between activities will ordinarily be cleared, prior to the shift, with the Bureau of the Budget and even the chairmen of the congressional subcommittees which normally review the program's budget esti-

mates. This clearance is made to avoid, in subsequent budget hearings, any question as to the agency's good faith in submitting budget estimates.

Since an appropriation limits the funds to be used, some balance must be retained and lapsed to protect the appropriation from a deficiency. Unrecorded obligations must be charged against appropriations for the year in which obligations were incurred. This may occur at any time up to 2 years after the close of the budget year before obligated balances of funds are merged and lose their time-period identification.

Conclusion

The budget can be a source of frustration to a program person who sees a need for spending more money than is available. The needs are as many and as varied as the programs sponsored by governmental units. The pressures for greater expenditures, however, are offset by the pressures of the people for limiting or reducing taxation. In a democratic society, the balance of governmental wants and satisfactions are adjusted slowly as the people express their wishes through their elected representatives.

on Appropriations). A single subcommittee of the House group considers appropriation bills for one or more agencies. The subcommittee studies the material in the budget, consults with its staff employees, and holds hearings at which the agency head and other key officials are asked to appear. Members of the subcommittee may question them on any point relating to the proposed budget in order to assure themselves that any money appropriated will be spent for approved purposes.

In appearing before congressional committees, agency witnesses are required to defend the President's budget. This requirement is implied, as pointed out above, from the section in the Budget and Accounting Act of 1921 which directs the President to submit a budget of his work and financial programs and prohibits any other employee of the executive department from submitting any other recommendation unless requested to do so by a member of Congress.

Only when specifically requested by a member of Congress may the agency witness offer an opinion or estimate which would be critical of the budget document.

The subcommittee makes its recommendation to the full committee on appropriations. The full committee's recommendation is introduced into the House, accompanied by a printed report that summarizes the programs to be financed and the comments of the committee with respect to them. After debate, the House approves the bill and passes it on to the Senate.

Senate consideration follows substantially the same pattern, and ultimately the appropriation bills are passed by this body.

Differences between the House and Senate versions of appropriation bills are negotiated by "conferees" appointed by each House. Conferees are authorized only to act on differences. They may not consider items not in dispute, but within the range of differences, they have complete freedom to negotiate. Conference recommendations are subject to approval by each House.

When a bill is agreed upon by both Houses of Congress, it is submitted to the President. When he signs it, the appropriation bill acquires the status of a law.

Execution and Control

Enactment of an appropriation bill does not automatically make funds available for use. The funds must first be apportioned by the Budget Bureau. As explained in the glossary on p. 791, apportionment is a method of approving the use of appropriated money generally on a time-interval basis, usually quarterly, to avoid deficiency appropriations. The Budget Bureau also uses the apportionment process to review again the budget program, in light of current conditions, before it is put into operation.

The Budget Bureau has the authority to withhold funds and place them in reserve "to provide for contingencies, or to effect savings whenever savings are made possible by or through changes in requirements, greater efficiency of operations or other developments subsequent to the date on which such appropriation was made available" (5).

In the absence of any specific information to the contrary, funds apportioned and unused in one quarter are automatically available in the succeeding quarters within the budget period. In an annual appropriation, apportioned and unused funds cannot be carried over to another fiscal year without legislative approval.

After funds are apportioned, they are allotted by the head of the agency, or his designee, to the person responsible for the operating program. This individual may reallocate or suballot these funds to lower program levels.

Each allottee is liable to remain within the limits set by the allotter. Every violation, technical or otherwise, must be reported to the President through the Budget Bureau and to the Congress. These reports outline the circumstances of the violation and the action taken against the allottee, if it was due to his negligence. They also review the adequacy of the system of control to prevent recurrence of a deficiency.

In order to obtain maximum efficiency in the use of budgeted resources, provision must be made for continuous statistical and financial evaluation of programs. Data obtained should be used to inform management, at all levels, of changing patterns of program operations. They provide a basis for program evaluation of

Economic Costs of Disease and Injury

SELMA J. MUSHKIN, Ph.D., and FRANCIS d'A. COLLINGS, M.A.

WHAT is the cost of sickness and the price of health? What are the costs and prices of alternative health activities and how much should be spent for control of a disease as compared with other programs? What can we afford to do, and afford not to do, in meeting disease problems?

Such questions are raised repeatedly about the costs of specific diseases and about comparative amounts spent for prevention and treatment. These are issues which quantification of costs and prices cannot resolve alone; but, as Winslow emphasized, such quantification can provide a most valuable tool to assist in consideration of these issues (1).

The arithmetic of economic gains and losses brought about by health programs can be an important tool, especially in planning for economic development in parts of Asia, Africa, and South America. For these countries, the real price of health programs often includes not only expenditures for public health programs but also costs occasioned by pressures of population growth. These pressures have been intensified by a marked fall in death rates from the application of modern public health measures and techniques. It has been estimated, for example, that the introduction of modern medical technology into some of the nonindustrial nations has resulted in a decline in mortality and a net increase of 1 to 2 percent in population per year.

While cost-price equations have more urgent application in health programing in nonindustrial nations of the world, they also apply to

health programing in the United States. They supply a tool for appraising the adequacy of resources devoted to specific health problems and the comparative economic returns from public investment in different disease problems. They permit a summary type of comparison between the costs of a specific disease and the price of the health care associated with the disease. With this type of summary in view, the National Health Education Committee collects information on the major killing and crippling diseases in the United States (2).

Review of existing work on costs of specific diseases and health programs, however, suggests a need for clarifying cost concepts in current use, setting forth in a summary way the information now available to estimate costs, and assessing the additional information required. This paper attempts to meet this need by setting forth a tentative classification of costs based on their effects on the use, distribution, and quantity of economic resources, which may help clarify the concept of economic costs of disease. In the context of each of these cost components, the types of information available for measurement are discussed and the additional information required is summarized.

Economic costs, as we are viewing them here, arise out of the impact of disease and injury upon economic resources. The question we must ask is: What is the difference between what actually happens in the economy now and what might happen in the hypothetical situation where sickness from specific causes is eliminated? In other words: What is the impact of a disease upon the use, distribution, and availability of economic resources?

Economic costs may be more sharply de-

A new city health code was enacted in March 1959 by the New York City Board of Health. It will become effective October 1.

The code, the result of work in progress for 3½ years, is divided into five titles: general powers of the department of health; communicable disease control; maternal, infant, child, and school health; environmental sanitation; and records and vital statistics.

Deleted are obsolete provisions such as the requirement that barber-shops, hair dressing and beauty parlors provide cuspidors, and the responsibility of the department to mark the location of dead horses on city streets by placing lighted lamps at their heads at twilight.

Added responsibilities under the new code are control over radioactive materials and X-ray machines, chemical food additives, medical laboratories, and day care centers for children.

Dr. Leona Baumgartner, the city commissioner of health, commented: "The old code was bacteriologically oriented. We realize now more than we did 45 years ago that our environment is more than bacteria. The new one continues the safeguards and broadens the scope to protect us against other hazards."

One-half of the accidents which put farm residents in the hospital occur in farmyards with children the most frequent victims, it was found by the accident prevention program of the Saskatchewan Department of Public Health, Canada. This finding launched a "safe play areas for farm children" project. Farmers are being supplied with do-it-yourself blueprints of simple and safe play equipment which they can make during winter months.

modities complementary to health services, for example, eyeglasses and hearing aids, identify special costs connected with some conditions.

5. Number and income of providers of services whose specialty relates to a disease category, such as psychiatrists and ophthalmologists, are indicators of special costs.

6. Expenditures under public and private agency programs earmarked for services, research, or prevention in a special disease category provide a source of costs.

7. Allocation of "overhead" costs, such as costs of training health personnel and construction of facilities, to a disease category can be based on some index of relative importance like number and use of personnel and facilities.

There are several possible methods of combining these approaches. Expenditures can be classified in terms of who pays the bills, either initially or ultimately. Much of the information now available on aggregate health expenditures in the United States is classified in this way: by expenditures of Federal, State, and local official agencies, insurance carriers, employers, and private persons (5, 7). Another classification is by the category of services purchased, for example, dental or hospital (8, 9). A third classification is by age group of patient. Recently, a World Health Organization study suggested still another type of classification based on a rough index of the physical status of the patient, that is, whether the patient is in a hospital, is ambulatory, or is at home on his back (10). In each of these classifications, preventive services may be distinguished from curative services, and current outlays from capital outlays for plant and physical facilities.

Sources of data for estimating the resources consumed by a specific disease vary by the nature of the disease, the identification of medical specialties and special hospitals with the disease problem, and the extent of identifiable public and private support for the agency program. Some of the source data represent national compilations of statistics on facets of expenditures, but for the most part the materials must be drawn from special regional or community studies. References to such special studies are compiled by the clearinghouse on morbidity projects of the Public Health Service (11) and by the Health Information Foundation (12). Detailing each source of data for estimates on expenditures for specific disease categories is

outside the scope of this paper. The general types of source data, however, are as follows:

Public hospital expenditures. Data on mental hospitals are compiled annually by the National Institute of Mental Health, Public Health Service (13); expenditures on tuberculosis hospitals and tuberculosis control are compiled by the Bureau of State Services, Public Health Service (14). In some communities, information has been tabulated on public hospital use by diagnosis, for example, morbidity in New York City's municipal hospitals (15). Similar material on Federal hospital use by diagnosis is brought together by the Veterans Administration, the Public Health Service, and the Defense Department and is being collected as a byproduct of the administration of the medical care program for dependents of the uniformed services.

Other public expenditures. Data are available on research and related training expenditures for specific disease categories for which separate appropriations are made by the Congress. These amounts are published as part of the U.S. budget and also in the reports of the National Institutes of Health (16).

Household surveys of health service costs per illness case. A number of special household surveys have been made on the nature of illness in population groups, including medical services received and cost of such services. The North Carolina Agricultural Experiment Station, for example, has made such a study from samples of population in Stokes and Montgomery Counties, N.C. (17). The Research Council for Economic Security has studied the volume of prolonged nonoccupational illness among 400,000 employees in private nonagricultural employment, and the types and cost of treatment (18); a survey in Lyon County, Kans., included data on amount and types of different health services as well as costs of hospitalization and cause of hospital care (19); and the Kansas City regional health and hospital survey also included information on both health services and conditions reported (20).

Surveys of patients. A number of different types of sample surveys have been made of persons in hospitals or other institutions and of physicians' patient loads which include, along with diagnostic information, data on use

fined into three types: The first is actual use of economic resources (manpower and materials) for prevention, diagnosis, treatment, and rehabilitation. This represents the direct price of health programs; it is measured by actual expenditures, both public and private, for health services and their complement of commodities and facilities. In the absence of disease, these expenditures would not be necessary. The second type consists of transfers (of resources or of income) which arise out of mitigating the burdens of sickness. Costs in this category do not, in the first instance, affect the total resources used up by sickness in the economy as a whole, but they do affect the distribution of resources among individuals or families. Many of these transfers are designed to mitigate the impact on family income of losses due to death or disability. The third type, less clearly defined but perhaps more pervasive in effect than either of the other two, is loss of resources occasioned by sickness—human resources lost or impaired as a result of death, disability, and debility caused by sickness.

For convenience, we will call these three categories of cost resource-use, resource-transfer, and resource-loss. Other classifications have been used. Dr. Raschi Fein, in a recent work for the Joint Commission on Mental Illness and Health, used direct and indirect cost to refer to resource-use and resource-loss respectively. He combined the transfer category with direct costs (3).

Resource Use

Each of the major diseases and disabilities requires the use of manpower and material for prevention, treatment, and rehabilitation. If it were not for disease and injury, these resources of men and material could be used to produce other want-satisfying goods and services. The actual use of these resources in the health industry thus constitutes the type of cost of sickness that we have termed resource-use.

Available estimates suggest that the part of the Nation's manpower and of goods and services produced that is devoted to health care has increased in recent years. In 1929, the Committee on the Costs of Medical Care estimated

health and medical expenditures at \$3.9 billion (4), or 3.8 percent of the gross national product; an estimate by the Social Security Administration for 1957 showed that the health share of the Nation's output had risen to 4.7 percent (5).

The resources directly devoted to the research, prevention, diagnosis, treatment, and rehabilitation in a specific program or disease category are represented by the outlays of public and private health agencies, employers, and individuals and their families. They include expenditures for (a) health services provided by physicians, hospitals, dentists, nurses, and other health personnel; (b) complementary commodities such as drugs, prosthetic appliances, and medical supplies; (c) public health programs, including, for some disease categories, environmental health services; (d) medical research; (e) a part of costs of training health personnel; and (f) a part of capital expenditures for construction of health plant and facilities used in the provision of health services and the production of complementary health goods.

While progress has been made in the development of estimates for global health expenditures which encompass most of these categories of outlays, figures in current use for specific diseases fall far short of even a complete count of expenditures for hospital and physician services, both public and private (2,3,6).

Estimates of expenditures by disease category may be approached and combined from available data in several ways. The following summary of methods consists partly of alternative approaches and partly of methods for approximating additive segments.

1. Data on average cost per case of a disease times number of cases give a rough approximation of total cost of a disease.

2. If the average cost per case is not known, average duration of hospital care, times number of cases, times cost per unit of service, plus average drug use times costs of other health services yields a similar approximation.

3. Expenditures (both current and capital) of hospitals and nursing homes specially designed for a specific disease can indicate the costs, as can the allocation of expenditures of general hospitals (or nursing homes) based on hospital use by diagnosis.

4. Expenditures for specific disease-connected com-

nesses for which data are sought, such as cerebral palsy cases. The Health Information Foundation in its 1952-53 survey attempted to obtain information from the surveyed families on both expenditures and health conditions but the illness data were not tabulated (35). A review of the information obtained by the Bureau of Labor Statistics in its 1950 survey of urban families on the illness for which the major part of the family's medical care expenditures were incurred indicated that the information reported was too sparse to permit analysis by disease category (36).

Another step in obtaining materials for estimates of expenditures by specific disease category would be to gather more information as part of the National Health Survey. A tabulation of information on physician visits and on practical and professional nurse services by nature of condition would make a beginning toward approaching expenditures through volume of services. Other health service items and commodities might be incorporated on the questionnaire for special analysis. Information on number of prescriptions, X-ray services, ambulance services, laboratory tests, oxygen, transfusions, and on physical and occupational therapy services and public health services might be obtained. It would probably be desirable to develop a series of questions on health services used for several major disease categories on a supplement to the general questionnaire for surveyed families.

Other approaches might be followed in the collection of information, such as a sampling of hospital and physician records to define the classes and volumes of services used in the diagnosis and treatment of the major diseases, and the independent collection of price data for the defined classes of health services and commodities used. Collation of public expenditure data for specified disease categories would also facilitate the approximation of aggregate expenditures for a disease. The National Institute of Mental Health has worked toward the collection of costs of mental illness not only by assisting in improved financial reporting from State hospitals but also by bringing together other data on public expenditures for mental patients, but these data combining

Federal and State mental hospital expenditures are not published.

Resource Transfer

Disease and injury occasion not only a direct use of economic resources for the provision of health services and supporting goods but also transfers of income between the sick and the well. These transfers are costs to the givers, benefits to the receivers; but because they entail a reallocation of resources away from uses which, in the absence of sickness, would be preferred, transfers must be considered in assessing the economic impact of disease.

The size and importance of these transfers in the American economy have increased rapidly in the last two decades. They take two principal forms. One consists of payments made directly to the sick and disabled (or their survivors) and financed from taxes or contributions levied; social security protection under public and private auspices is the principal example. The other is the hidden redistribution of the tax burden that comes about through statutory tax provisions designed to assist families and voluntary agencies in meeting problems arising out of sickness. On both these counts, disease takes resources away from those who are well, and who would otherwise have alternative uses for them, and gives them to those who are sick and to survivors.

Cash Payments

A wide range of cash payments are made to individuals to mitigate the effects of loss of income due to death and disability. It is difficult to distinguish transfer payments attributable to sickness alone. For example, a part of old-age assistance and of old-age insurance benefits are paid because the aged person became disabled and was forced to retire. Under Federal programs, payments are provided to disabled veterans, to survivors and the disabled under the old-age, survivors, and disability insurance (OASDI) program, under the Civil Service system, and under the railroad retirement program. Compensation benefits for work connected with injuries are paid to Federal employees and sickness benefits to railroad

of the different classes of health services, or cost of care or treatment. One example is the Dane County, Wis., survey of services and cost of treatment of the aging and long-term patient (21). A nationwide study of all patients discharged in a week in 1956 by hospital use and diagnostic category as well as of physician services received has been made by the Bureau of Medical Economic Research of the American Medical Association (22). A nationwide study is reported to have been made of drug therapies and morbidity reported by physicians based on case records kept on patients seen in private practice during a 2-day period.

Prepayment plan and insurance carrier data. Some compilations have been made of the experience under prepayment plans such as Health Insurance Plan of Greater New York and Kaiser-Permanente indicating volumes of selected health services for different conditions or hours of professional work time involved for different procedures (23-26). Insurance claims data which have been published for special purposes also provide useful materials (27). Fairly detailed data on costs by diagnosis are becoming available in administration of the Medicare program and provide an important source of cost information for the types of conditions to which the Medicare beneficiary group are subject (28).

Census and trade data. For some types of health commodities, such as hearing aids, eyeglasses, and drugs, data are available from the retail, wholesale, and manufacturing censuses conducted by the U.S. Census Bureau and from trade journals such as *American Druggist* and *Drug Topics* (29-31).

Professional income, fees, and hospital rates. The publication *Medical Economics* has put out information from a sample of physicians on gross and net physician income by specialty (32). Fee allowances for specific procedures are set up by Blue Shield plans, Medicare, Veterans Administration, and in the course of administration of other health programs. Hospital charges and costs are available from the publications of the American Hospital Association, regional hospital councils (33), and from public medical care programs. However, these hospital data are not generally classified by disease category.

National Health Survey. Perhaps the most important single source of data by nature of condition or diagnostic category is the National Health Survey (34). From the household surveys, information is being obtained on the condition reported at the time of the interview. In the medical examination survey, information is being obtained on selected conditions for which standard diagnostic procedures have been developed. In both types of surveys, data are being collected on items of medical service use, including hospitalization, physician visits, dental visits, nursing care, and use of specified special aids (hearing aids, artificial limbs, braces, and wheelchairs). Information from the household survey on numbers of days of hospital care and average length of hospital stay have been published for specified hospitalized conditions including malignant neoplasms, heart diseases, arthritis, hernia, fractures and dislocations, and infective and parasitic diseases. Dental visits have been published by type of services received. Other types of services have not been related thus far to the nature of the condition reported.

The various estimates that have been compiled of resources devoted to health services and related commodities on account of specific diseases point up the inadequacies of existing information on which such estimates are based. Additional collection of expenditure data cross-classified by nature of illness is needed.

The problems of collecting information of this type are many. Household surveys are limited by the types of conditions that families are likely to report, and by the undercount of expenditures for terminal cases. Many household surveys omit institutional populations. In addition, with the increase in voluntary health insurance coverage, expenditures for services are paid by the insurance plans and families often have no record of these costs. Other more technical problems include the use of health services and drugs for multiple conditions, the difficulties of obtaining accurate reporting on relatively small expenditure items, and memory biases in reports from households in which detailed expenditure records are not kept.

Small sample studies, moreover, yield an inadequate number of cases on many of the ill-

nesses for which data are sought, such as cerebral palsy cases. The Health Information Foundation in its 1952-53 survey attempted to obtain information from the surveyed families on both expenditures and health conditions but the illness data were not tabulated (35). A review of the information obtained by the Bureau of Labor Statistics in its 1950 survey of urban families on the illness for which the major part of the family's medical care expenditures were incurred indicated that the information reported was too sparse to permit analysis by disease category (36).

Another step in obtaining materials for estimates of expenditures by specific disease category would be to gather more information as part of the National Health Survey. A tabulation of information on physician visits and on practical and professional nurse services by nature of condition would make a beginning toward approaching expenditures through volume of services. Other health service items and commodities might be incorporated on the questionnaire for special analysis. Information on number of prescriptions, X-ray services, ambulance services, laboratory tests, oxygen, transfusions, and on physical and occupational therapy services and public health services might be obtained. It would probably be desirable to develop a series of questions on health services used for several major disease categories on a supplement to the general questionnaire for surveyed families.

Other approaches might be followed in the collection of information, such as a sampling of hospital and physician records to define the classes and volumes of services used in the diagnosis and treatment of the major diseases, and the independent collection of price data for the defined classes of health services and commodities used. Collation of public expenditure data for specified disease categories would also facilitate the approximation of aggregate expenditures for a disease. The National Institute of Mental Health has worked toward the collection of costs of mental illness not only by assisting in improved financial reporting from State hospitals but also by bringing together other data on public expenditures for mental patients, but these data combining

Federal and State mental hospital expenditures are not published.

Resource Transfer

Disease and injury occasion not only a direct use of economic resources for the provision of health services and supporting goods but also transfers of income between the sick and the well. These transfers are costs to the givers, benefits to the receivers; but because they entail a reallocation of resources away from uses which, in the absence of sickness, would be preferred, transfers must be considered in assessing the economic impact of disease.

The size and importance of these transfers in the American economy have increased rapidly in the last two decades. They take two principal forms. One consists of payments made directly to the sick and disabled (or their survivors) and financed from taxes or contributions levied; social security protection under public and private auspices is the principal example. The other is the hidden redistribution of the tax burden that comes about through statutory tax provisions designed to assist families and voluntary agencies in meeting problems arising out of sickness. On both these counts, disease takes resources away from those who are well, and who would otherwise have alternative uses for them, and gives them to those who are sick and to survivors.

Cash Payments

A wide range of cash payments are made to individuals to mitigate the effects of loss of income due to death and disability. It is difficult to distinguish transfer payments attributable to sickness alone. For example, a part of old-age assistance and of old-age insurance benefits are paid because the aged person became disabled and was forced to retire. Under Federal programs, payments are provided to disabled veterans, to survivors and the disabled under the old-age, survivors, and disability insurance (OASDI) program, under the Civil Service system, and under the railroad retirement program. Compensation benefits for work connected with injuries are paid to Federal employees and sickness benefits to railroad

workers. In cooperation with the States, the Federal Government finances payments to the needy blind, disabled, and aged. Under State and local laws sizable cash payments are made to families whose income has been impaired by sickness. These cash payments include workmen's compensation benefits, cash sickness benefits (in four States), benefits under State and local retirement systems, and a part of the general assistance caseload as well.

Figures on these public outlays are available, and give some idea of the magnitude of resource-transfer under public auspices that occurs in our economy as a result of sickness. Disability payments under social insurance and related programs alone total more than \$3.5 billion at the present time (37). Aid to the needy blind and disabled under the assistance program accounts for an additional \$340 million per annum (38).

Private health, sickness, and disability plans have reached major proportions, but data in this area are piecemeal and often incomplete. In 1957, employer contributions to private pension and welfare plans totaled \$7 billion (9). Alfred M. Skolnik, of the Social Security Administration, has estimated premiums paid under group cash sickness insurance plans alone at \$134.5 million. A survey of 3,100 firms employing 6.8 million persons made by the National Industrial Conference Board found that 85 percent of hourly workers and 75 percent of salaried workers were covered under group accident and sickness insurance (39); the benefits for slightly under half of these employees were paid for entirely by the employers, and in almost all the remainder the employers contributed substantially.

Current practice in national income accounting does not define employer contributions to disability, cash sickness, and life insurance plans as transfer of income. They are regarded as supplements to wages and salaries, thus as part of the current return for productive services given. These contributions, however, are essentially pooled and go to finance payments to survivors and to those who are sick or disabled. The benefit payments accordingly represent from our point of view not an addition to national output but a shift in the shares of the national output from all workers cov-

ered to those whose income is impaired by death and disease. However, if sickness were miraculously eliminated it may be assumed that these employer payments would go instead directly into wages and salary compensation for the services.

Data on total benefits for each of the various types of protection are piecemeal and incomplete. For specific disease categories, they are even less adequate. Under the OASDI program, data are available on the number of beneficiaries by disability group and primary diagnosis, although amounts paid are not tabulated in this way (40). Benefits paid to disabled veterans, by broad disease categories, are included in the Annual Report of the Administrator of Veterans Affairs (41), but more detailed figures are not published. Benefits paid under State workmen's compensation programs are not recorded on a national basis, but some States publish data by diagnostic category. Some studies of State temporary disability insurance programs provide information on benefits paid by cause of disability (42).

Hidden Subsidies

The tax structure is increasingly being used to foster redistribution of income in the interests of specific public program ends. This amounts to a form of hidden subsidy. Under National, State, and local statutes there are a wide variety of exclusions, exemptions, deductions, and allowances made for reducing the costs of operating health facilities, for stimulating private giving, for reducing the burden of taxation on families incurring sickness and disability. For every deduction, or equivalent means of reducing the tax on those who are sick, there must be a corresponding increase in some other tax source to maintain a given level of revenue. Tax relief for some groups, for example those who are sick, means larger tax burdens for others. The losses in revenue from those who contribute to health agencies, who take deductions allowed for medical expenses, or who deduct income received as sick pay must be made up in the form of higher tax rates or additional tax levies. This shift in tax burden represents a shift in income after taxes and in the distribution of funds available for consumption among families.

Estimates of the magnitude of resources transferred in this indirect way are naturally lacking in precision. Some illustrative magnitudes may be suggested. Deductions from income on account of medical expense amounted to \$3.5 billion in 1956, the latest year for which data are available (43). Sick leave pay and cash sickness benefits deducted from income amounted to \$1.4 billion (43).

A large part of these costs appear again either as resource-use or resource-loss. The hidden transfers are not generally additive to these other types of cost because they do not represent a change in the total cost to the community as a whole; they represent rather a shift in command over income within the community. Similarly, cash transfer payments in large part represent payments made to individuals and families to partially compensate them for a loss in earnings represented more fully in the estimates of loss in labor product due to deaths and disabilities. Cash transfers included in the resource-loss estimates are not an additional cost item; where they are added there is a double counting (3). However, in the absence of estimates of resource-loss, cash transfer payments as a partial measure of income loss attributable to a disease may be added to resource-use.

Resource Loss

The type of sickness cost we have categorized as resource-use relates to the way in which existing economic resources are diverted to the sector of the economy that produces health services. Without sickness and injury, these health services would be unnecessary and the resources would be free for other productive uses. Resource-transfer represents shifts in command over resources between persons or groups, which may be direct costs to one sector of the economy but are of benefit to another. However, sickness and injury also affect the quantity of resources available in the first place. Disease and impairments cause a loss of economic resources, a loss that would cease if disease and injury were to be eliminated. This is also part of the total economic cost of sickness.

The resource lost as a result of sickness is human labor. In order to value the loss in dollars, it is necessary to estimate the output

foregone. The question is, if there were no sickness how much would those persons who are now sick have produced?

The effects of sickness upon the amount of human labor available for productive purposes can be summarized under three heads: deaths (loss of workers), disability (loss of working time); and debility (loss of productive capacity while at work).

Essentially, there are two stages in calculating the output foregone: (a) estimating the loss in productive work time, and (b) assigning a money value to the output that this lost work time represents. The result is then a dollar figure which represents the value of the loss in output attributable to deaths, disability, and debility. In other words, it is a rough estimate of the increase in output that would occur if the loss of resources due to sickness were eliminated.

In view of the conceptual difficulty of the idea of resource-loss, we will explain the problems involved in arriving at an estimate at somewhat greater length than we have done for resource-use and resource-transfer.

Conceptual Problems

An estimate of work-loss due to a disease involves the assumption that, if it were not for the disease, those persons in the productive age groups stricken by the disease would have been employed. In fact, where there is unemployment or substantial underemployment, improved health may result in more unemployment rather than more output. One obvious reason for using the simplifying assumption of full employment is that unless we do so we cannot arrive at any definite concept of what the resource-loss is. Apart from this, however, the fact that production losses resulting from poor health cannot be realized in an unemployment situation should be attributed to unemployment, not to ill health. Unemployment has its own costs which in effect may cancel out reductions in the costs of sickness, but for analytical purposes it is valuable to distinguish between the two. We, therefore, measure the costs of disease in the assumed absence of costs of unemployment, recognizing, however, that unemployment itself may have an impact on the incidence of illness (44).

There is another assumption implicit in the view that loss in production due to death, disability, and debility can be attributed to a particular disease. This is that the persons who die from or are disabled by the disease would otherwise be in good health. Here again, it is possible that persons saved from one disease may promptly die of another, and their production thus be lost in any case. It seems reasonable enough to disregard this possibility for clearly defined diseases that strike primarily at persons of working age; but it is less reasonable for cases where the disease, or treatment required to overcome it, weakens the patient by making him more prone to other ailments, and for cases when the disease strikes mainly at persons who are constitutionally weak in any case, as with the diseases of old age. In these cases, the loss in production can less clearly be identified with the effects of one disease. The result of disregarding the presence of multiple diseases is an overestimate of the cost of any single disease. At some later stage in refinement of the concept of disease cost, a methodology must be developed to deal with this problem.

Moreover, the assumption that side effects of other diseases may be disregarded in order to measure the direct effects of the disease in question means that the indirect costs of each disease, taken individually, cannot be added together to make a meaningful total for all diseases. Conceptually, such a summation could be made only if all alternatives to every disease were eliminated, in which case there would be nothing to sum. This problem illustrates the difficulty in applying the concept of resource-loss, as we are describing it here, to sickness as a whole.

The time scale of any estimate of resource-loss due to sickness involves further problems. Conceptually, it is possible to view the loss in production as (a) the loss in a given time period (for example, 1 year), (b) the loss over a productive work life.

The first of these seems most relevant to the present discussion because it is most nearly comparable to the types of estimates of resource-use and resource-transfer described earlier. It should be recognized, however, that death and permanent disability this year have a continu-

ing cost in terms of productive resources lost in the years that follow. Cost studies by Weisbrod (cancer, poliomyelitis, and tuberculosis), Malzburg (mental illness), Reynolds (road accidents) and Laitin (cancer) relate their estimates to the second of these concepts, the loss over a productive work life (45-48); the Fein study on the cost of mental illness developed 1-year estimates as well (3). The emphasis upon the lifetime estimate is perhaps due to the far-reaching influence of Dublin and Lotka's "Money Value of a Man," which presented an actuarial approach to this problem; but the authors of this work recognized that their method might not be applicable to the economy as a whole; it was intended originally to value a life for indemnity purposes only (49).

The 1-year estimate is conceptually much simpler, involves fewer assumptions, and in addition yields the most conservative estimate of resource-loss; for these reasons, we feel it to be the most appropriate measure in this context. The difference in estimates derived by these alternative approaches will not be so great as might appear at first, because (a) the appropriate disability figure in the case of a single-period estimate is that of disease prevalence, whereas in the case of a lifetime estimate it must be disease incidence, and (b) a rapidly diminishing value is attributed to future output in the process of placing a present value on these future earnings. Different interest rates assumed will affect the rapidity of the decrease as illustrated by the Weisbrod study which used alternatively interest rates of 4 and 10 percent—these being based respectively on the cost of long-term Government borrowing and the rate of return on corporate taxes (45). Conceptually the two types of estimates—for a single year and over a lifespan—must be regarded, however, as distinctly different.

There has been suggested earlier a threefold classification of resource-loss: losses from death, disability, and debility. In practice, these categories need closer definition, and it may be necessary to subdivide them further to make them correspond to available data.

Death is unambiguous in meaning, but cause of death is sometimes not. In estimates of resource-loss caused by a particular disease, deaths from multiple causes may need to be treated

differently from those caused by the disease in question alone. Disability caused by sickness may be partial or total, and it may be short term or long term. Cases of long-term disability, especially when total, may be found primarily in institutions, and thus it may be convenient to subclassify again into institutional and noninstitutional populations and use data available on institutional cases to measure a part of the disability caseload. The division between disability and debility, furthermore, will not be clearcut in many cases.

Loss of Working Time

The loss in resources through death, disability, and debility must, for the first stage of the estimate, be stated in terms of units of productive work time lost. The second stage to be dealt with later is to assign a value to these units. In the case of death and long-term disability, these units of work time are lost because of subtractions from the productive work force. With short-term disability, the loss will take the form of periods of lost time from the job and these may be converted into equivalent units of full-time work lost. Debility, defined as reduced productive efficiency per man, too may be converted into full-time equivalents. For convenience, the following discussion will refer to man-years as the units of productive work time.

How the equivalent of the full-time work force is defined operatively is of central importance to the estimate. For purposes of a single-year estimate, for example, a decision must be made on the age limits within which persons who contract disease will be considered as productive workers. In the United States, the age of entry into the work force is usually considered as 14 years. This starting age is largely a historical carryover in definition which has been perpetuated for comparative purposes in spite of the trend toward later entry into the work force. The retirement age varies widely among different groups and in different areas; the average age of retirement for the United States is estimated at present at 68 years of age for men (50).

The consequence of this limitation of work-force participation, for a single-period esti-

mate, is to count the resource-loss from death, disability, and debility of the young and retired aged as zero. This is consistent with the definition, since persons outside the work force are not considered to contribute anything to production in the year in question. For the extended time-scale analysis, however, infant and childhood deaths represent a future loss to society and must be allowed for, although the time interval between death and anticipated entry into the work force may be such that the present value of the future loss of working time is small.

The importance of the retirement-age assumption will vary with different social and economic settings. In some economies, the urgency of production for survival leaves little room for retirement prior to death or total disability; with higher productivity and industrial advances, cessation of work activity becomes feasible before extreme old age is reached. In an industrial community, therefore, it seems reasonable to exclude retired persons who cease to contribute to production, but in others retirement may be disregarded.

Whatever age limitations are set upon the productive work force, further qualification is necessary because not all persons of productive age are actually engaged in production. At full employment, only a certain proportion of the members of each age group will be productively employed, and the loss in man-years attributable to these persons alone should be counted toward the estimate of resource-loss. Here again, this implies that the death or disability of a person not in the active work force occasions no loss of productive resources.

Special problems arise in the case of women working in the home. Such women are not normally included in standard definitions of the work force, and their product, unlike that of paid domestic workers, is not included in the national economic accounts. Thus defined, their death or disability is not an economic cost. However, this is clearly highly anomalous; it implies that the national product is increased if every wife does housework for pay for the family next door, and lowered if every man marries his cook. The only alternative is to impute some value to the services of housewives in the home, thus imputing an indirect cost to their

death or disability. Although proposals have been advanced for broadening the concept of production used for national product purposes to include such nonmarket services, no generally agreed way to do so at present exists (51). To simplify the estimate and to follow an approach consistent with national product accounting it seems desirable at this stage of analysis to omit the valuation of housewife services.

A related problem concerns the method of counting deaths and disabilities among unpaid family workers. In the United States and several other countries, unpaid family work is included in the national product accounts, in effect requiring a prorating of income among the working members of the family enterprise. In this case, there is a basis for allocating a value to the services of such a worker. The importance of this problem obviously varies in different social settings, but in countries where a large proportion of production is carried on on farms and in other family enterprises it would be clearly advisable to count deaths and disabilities among those who work within the family unit without money wages.

In estimates over a lifespan, work life tables developed by the Bureau of Labor Statistics may be applied which identify the remaining years of work life at each age group. Estimates of work life years have been developed for 1940 and 1950 for both men and women; and historical changes in the pattern of work life expectancies have been estimated for 1900 and projected to the year 2000 (52-54).

Further problems arise in connection with part-time workers. The loss of productive work time for a given impact of disease among these persons will be less than that among full-time workers, and this loss will have to be converted to a full-time equivalent for purposes of the estimate. The effect will be to consider the loss of, say, two part-time workers as being equivalent to that of one full-time worker; the exact ratio might be determined with reference to average hours of work or other available criteria.

The most practical solution to these definitional problems may be to use existing concepts of "work force" and "labor force" (converted to full-time equivalents) to distinguish the cases of the disease that result in actual loss of pro-

ductive work time. In the United States, the basis for classifying persons in or out of the "labor force" is their activity during a specified week. Employed members of the labor force comprise those at work for pay or profit during the survey week, those who worked without pay for more than 15 hours on farms or in family businesses, and those who would have been in these two categories in the work force but for vacation, temporary illness, bad weather, or industrial disputes. Unemployed members of the labor force comprise all those without work who were actively seeking work during the survey week. Data will often be available only within this framework, and this method has the further advantage that it makes the estimate of resource-loss comparable in scope with existing national product estimates. The effect, however, is to exclude almost all the nonmarket costs of death, disability, and debility from our estimate of resource-loss, and this should be clearly recognized as a serious source of understatement of the total.

Our measure of resource-loss is posited on the assumption of full employment. However, it may be felt desirable to make an allowance for frictional unemployment, that is, the essential unemployment that exists even at full-employment levels as when persons change jobs or are temporarily laid off. In the United States, this is usually considered to run at about 3 percent of the labor force at any time; thus 3 percent fewer deaths and disabilities than the total of those from the labor force actually affect production at any time. It is also desirable to allow for absenteeism over-employment, which is normal absenteeism of workers from jobs because of vacations, bad weather, and temporary sickness. These adjustments may be applied to the final estimate of productive work time lost due to the disease as a straight percentage reduction, or in terms of a full-time equivalent number of man-years.

It is apparent even from this brief discussion of the problems of defining lost work time due to disease that many of the factors involved are dynamic. The single-period type of estimate, which sets out to quantify the gain in work time in a given year that would result if a specific disease were eliminated, avoids the problems of estimating future trends in work-force partici-

pation. For the lifespan type of estimate, these problems could only be solved by making a large number of assumptions about the future course of such trends, and the uncertainty and complexity of the estimate would be greatly increased.

Loss of Output

The previous stage in the computation has resulted in an estimate of the productive man-years lost because of deaths, disability, and debility from sickness. This, in itself, may prove a useful piece of political arithmetic, but in most cases it will be desirable to translate this into dollar cost by assigning a value to the man-years foregone in terms of lost production.

In the available studies on losses from illness, two essentially divergent approaches have been used in assigning a value to each unit of labor work time. The first is to value each unit by an amount equivalent to total product per worker; the other is to use earnings as a measure of labor product per worker.

The first of these assumes, as Fein (3) has indicated, ". . . that all of the national product (income), and therefore any gains in national product, are attributable to labor rather than to some combination of joint factors of production, land, labor, capital, etc. Although it may, indeed, be true that if there were no labor there would be no product, it is equally true that if there were no capital there would be very little product."

The total-product-per-worker approach was used by Reynolds in his study of the cost of road accidents in Great Britain (47) and also in the National Planning Association study on the costs of tuberculosis in the United States (55).

The second alternative—to use earnings as a measure of the output attributable to labor—seems to us to be more appropriate for purposes of estimating resource-loss. Earnings, in this case, must be distinguished from income, which includes returns on property or capital; earnings consist only of wages and salaries (or equivalents for the self-employed). These wages and salaries are paid in direct return for productive services, and, according to economic theory, they correspond to the individual's contribution to production. The estimate of re-

source-loss put in these terms thus measures the loss of production attributable to labor which this earnings-loss represents.

A choice between these two alternatives arises also in estimates of the costs of unemployment, which are perhaps more familiar than those of the costs of disease. Here, however, gross product per worker seems the more appropriate concept, because it is fair to assume in these circumstances that some capital will be unemployed along with labor. This brings to light another assumption implicit in our concept of resource-loss from a disease: this is that the ratio of investment of capital to labor used remains approximately constant. If this were not so (as, for example, if the investment or capital stock were assumed to be constant and unchanging), the labor released by eliminating the disease might have to work with less capital per capita, and diminishing marginal returns to labor would ensue. A related implicit assumption is that the capital stock is infinitely divisible, so that there is no question of the product of each man being tied to the availability of a machine or implement.

The earnings figure used may be an average for all employed workers. This assumes that the average earnings pattern among those who contract the disease is the same as that of the working population at large. For greater accuracy, it would be preferable to use a series of averages applied to sex-age groups, occupational categories, or other subdivisions and to take account of the findings of studies relating earning levels and disease incidence.

The use of average earnings per full-time employed worker is in fact only an approximation of marginal earnings, which are needed to actually measure the additional labor product that would become available as a result of eliminating the disease. Under the assumptions of full employment of labor and constant labor-capital ratio that we have made, average and marginal earnings will be the same. In practice, however, if elimination of the disease were to throw a relatively large number of workers onto the labor market, it might be found that these assumptions would need to be relaxed for purposes of realistic prediction.

A word must be added about an argument

appearing sometimes in the literature (49) that a man's contribution to production should be considered net, exclusive of the essential consumption required to maintain him as a producer, rather than gross as we have taken it here. Quite apart from the virtually insoluble difficulty of defining "essential" consumption, the frame of reference of our problem is to determine the loss in total output caused by disease and thus by definition the gross approach is indicated. The fact that saving a life adds a consumer as well as a producer to the economic process is immaterial to an estimate of change in total output. Calculation of the resulting change in consumption levels per capita is basically a problem of resource-use rather than losses in production.

Average earnings multiplied by the number of man-years lost as a result of the disease yields the dollar estimate of resource-loss caused by a disease. We are now in a position to define the result more closely. It is, essentially, an estimate of the money value of the labor product lost as a result of death, disability, and debility due to a disease.

Gaps in Statistical Data

The foregoing summary of concepts and definitions in the measurement of output-loss due to a disease suggests the wide range of assumptions and approximations which must sometimes take the place of factual information in estimating the dollar amounts.

Statistics on employment patterns are applied to data on deaths by cause, age, and sex without taking account of the specific employment history of those who die. The assumption of average work-force participation is made necessary by the absence of specific information on employment status of the deceased. In fact, there will be differences in the importance to productivity of each death: elimination of a key worker in a basic industry, for example, might affect the ultimate output of hundreds of others.

Estimates of average full-time earnings are applied to deaths in the productive age groups without taking into account the differential death rates in different industries and occupations, which may pay different wages. The absence of recent data on deaths by occupa-

tional groups and by earnings classes necessitate the use of average figures.

Improvement of the estimates now in current use of the resource-loss due to deaths not only requires agreement on concepts and definitions for measurement, but also additional data on mortality by cause of death, relation of the deceased to the work force in a period preceding death, and occupation and earnings in a period prior to death.

Data on work-loss days for those attached to the work force have become available through the U.S. National Health Survey of the Public Health Service. These data, however, are published only for the following groups of conditions: infectious and parasitic, circulatory, respiratory, digestive, genitourinary, arthritic and rheumatic, injury and impairment due to injuries, other impairments, and all other conditions. Until such data become available for more specific disease categories, information on disease prevalence and on duration of illness will be combined with average work-force participation for age and sex groups to approximate the work-loss days. Moreover, data are needed on usual earnings rates received by persons reporting work loss due to a condition. The existence of multiple conditions yields an inflated count of work loss attributable to each condition and an overcount of the sum of days for more than one condition.

The impact of diseases which cause debility, or loss of working efficiency, is no simple matter to define. In its broadest dimension, a measure of loss of output due to disease debility requires formulation of a standard of output in the absence of the disease, from which shortcomings may be measured. Additional work is required on the concept of measurement, as well as on the collection of data permitting a count of lost product per unit of work time. In highly industrialized countries, machines have taken over much of the physical work of man, and maximum demands are seldom made upon the physical energy of the average worker in the mechanized industries. What, however, are the appropriate counts of maximum output in terms of human capacity in service and nonmechanized employment and of deviations from these maximums? In other economic settings, the energy capacity of a man at work may be of

great importance. In subsistence agriculture, reduction in debility from malaria, trachoma, or dysentery can be as important a factor in increasing productivity as a change in tools or technology.

Debility, where relevant, thus represents the least well defined of the three categories through which we examine the resource-loss from disease. However, its influence is so pervasive that some basis for estimating its impact on the economy is badly needed.

Conclusions

To summarize, the economic costs of disease and injury are of three types: (a) costs which use a share of the Nation's resources of manpower and materials to supply health services and their commodity components; (b) costs represented by the transfer of income and resources from the well to the sick in public and private efforts to mitigate the burdens of illness; (c) costs reflected in a reduced national production of all goods and services. These three types of costs are termed resource-use, resource-transfer, and resource-loss.

The price of control of a disease is the health resources used up in the treatment and control of a disease. In economies characterized by severely limited resources and low food supplies, there must be added the minimum essential consumption of people whose lives are saved by the successful disease control action.

The economic cost of a disease for price-cost comparisons is the loss in labor product, or the amount by which the national output in a year is reduced by death, disability, and debility.

The omissions and limitations of this type of economic arithmetic are many. The scheme fails to take into account the pervasive force for social and economic change released by improvement in mortality rates and changes in expectations of survival. Changes in life expectancy and in health status radically alter attitudes toward work and enterprise. Disease and early death are deeply implanted in the mores of many people of the world. The fears, superstitions, rigid social patterns, and resistance to change are in part cultural adjustments to high disease and death rates. While they are not to be changed overnight, one cause of

them will be removed when illness is limited and death rates sharply reduced.

Changes in expectation of life, moreover, alter individual attitudes toward sacrifice of some part of today's consumption for tomorrow's. The time perspective of planning and investment for economic development is deeply affected by health levels. A prospect of longer life disposes the individual to support long-run development projects because he sees for himself a better chance of reaping some of their benefits. Changes in life expectancy, especially of infants and children, offer some promise of adjustment, over a period of time, in size of family, fertility rates, and age structure of the population.

The accounting of economic gains and losses as described also omits what is perhaps the simplest and most direct economic effect of all. Health is itself an element in the standard of living. Concentration on health as an investment in economic resources—an intermediate product of value in that it helps to increase national output—must not obscure its parallel importance as a final product for human welfare.

Objection on ethical grounds has sometimes been raised to conversion of human lives to money terms, to the disregarding of human suffering and to the counting of saved lives of children and other nonproducers as a price rather than gain. The value of human life and relief of suffering obviously cannot be disregarded in health programing. Disease prevention and control measures which yield zero or even negative economic returns can be fully justified in terms of human values. The fact that the economic arithmetic of a disease is only one of a number of tools for evaluation of health programs does not in itself argue against development of cost estimates of disease.

Voluntary and public agencies concerned with specific diseases have developed or used such estimates to further programs of medical research and disease control. They have financed studies of these costs to give them a tool to describe the size of the problem in public discussion. Review of these studies indicates clearly the need for development of a conceptual framework for such estimates, for a clearer formulation of their assumptions and limita-

tions, and for indication of the areas in which relevant data still need to be collected.

ADVANCES IN PATHOLOGY

CONFERENCE REPORT

THE TRANSPLANT of human leprosy into animals, a new technique to detect cancer cells, a reevaluation of Buerger's disease, and an explanation of some causes of sudden death were announced at the annual meetings of the International Academy of Pathology and the American Association of Pathologists and Bacteriologists held April 20-25, 1959, in Boston, Mass.

Transplant of Human Leprosy

Experiments that appear to have achieved the long-sought goal of transplanting human leprosy into animals were reported by Dr. Chapman H. Binford, Public Health Service officer on duty with the Armed Forces Institute of Pathology, Washington, D.C.

In the experiments bacilli from skin specimens of leprosy patients were inoculated into 2 sets of 50 golden hamsters each, Dr. Binford said. Infections paralleling those of human leprosy in tissue pattern, number of bacteria within cells, and presence of bacteria within nerves appeared in the hamsters in the 18 months following inoculation.

Bacilli from these animals were then injected into a second group of hamsters, and in 5 months an infection that resembled leprosy again appeared. Bacilli from that group have been transferred to a third set of hamsters with apparently successful results.

The golden hamsters were inoculated in their ears and testes. The temperatures of these sites are lower than those of other regions of the body, and the micro-organism *Mycobacterium leprae* in man is known to prefer low-temperature regions.

One group of hamsters in each experiment was given injections of heat-killed bacilli as a control measure. None developed infections. During the 3-year investigation, 35 different inoculation experiments were tried in more than 1,500 small animals. Inoculation was unsuccessful in guinea pigs, albino hamsters, white rats, white mice, hairless mice, and monkeys.

The research was a joint effort by the Laboratory Branch, Communicable Disease Center, Public Health Service, at Chamblee, Ga., the Armed Forces Institute of Pathology, and the Leprosy Registry, American Registry of Pathology, of Washington, D.C.

Dr. Binford emphasized that the results of the experiments must be viewed with caution and confirmed by repetition. He hopes that other researchers will try to reproduce his results.

During the 85 years since Dr. Gerhard Hansen discovered the leprosy bacillus, claims of successful culture of the bacteria in laboratories and production of the disease in animals have been made and later disproved. Verification of results is difficult because there is no laboratory method for positively identifying the bacillus.

Inability to grow *M. leprae* on artificial media or to infect laboratory animals has hindered research on leprosy. If stable, regularly reproducible lesions due to the leprosy bacillus are acceptably established in the hamster or other animals, many objective studies of leprosy can be undertaken in research laboratories. Among these would be search for more effective treatment, experiments in transmission, exploration of immunological processes, and renewed investigations in bacteriology.

Cancer Cell Detection

By employing a fluorescent orange dye, pathologists at Walter Reed Army Hospital have halved the time required to detect cancer cells in smears taken in cytology examinations, stated Capt. Leroy H. Dart, pathology resident, and M. Sgt. Thomas R. Turner, cyto-technologist. They said that 5,491 microscopic preparations stained with the new dye, acridine orange, were examined twice as rapidly and just as accurately as with the Papanicolaou technique.

The technique they reported represents a modification of the acridine orange method introduced by Ludwig von Bertalanffy.

The dye causes nucleic acids present in the cells to give off a green and red fluorescence. Cancerous cells, which contain increased amounts of nucleic acids, show an extremely bright fluorescence under the microscope.

Captain Dart pointed out that the method is used only as a screening examination. When the possible presence of cancer is indicated, final diagnosis is made by microscopic examination of a biopsy specimen. The laboratory service of Walter Reed Army Hospital has adopted the fluorescent dye technique for routine examination of smears.

Buerger's Disease

Buerger's disease may not be a disease entity at all in the opinion of a group of medical investigators associated with Beth Israel Hospital and Harvard Medical School.

The researchers were Dr. Stanford Wessler, associate in medical research at the hospital

and assistant professor of medicine at Harvard; Dr. Si-Chun Ming, senior fellow in pathology at the hospital and clinical associate in pathology at Harvard; Dr. Victor Gurewich, former resident in medicine at the hospital, and Dr. David G. Freiman, pathologist-in-chief and director of laboratories of the hospital and clinical professor of pathology at Harvard.

They suggested that what was once diagnosed as Buerger's disease and resulted in blockage of the arteries in the extremities of the body is due to the formation of blood clots in the arteries and veins or to atherosclerosis. They compared 123 new patients with a diagnosis of Buerger's disease with 1,365 new patients with other forms of arterial disease admitted to Beth Israel Hospital from 1929 through 1956.

The number of diagnoses of Buerger's disease steadily declined, and none was made after 1950. "This suggests increasing reluctance on the part of physicians to make the diagnosis on clinical grounds alone," the researchers stated.

Historically Buerger's disease stems from a pathological description in 1908 by a New York physician, Dr. Leo Buerger. Impressed by the occurrence of gangrene in a small number of young men, he described certain characteristic clinical and pathological features which, he believed, distinguished the vascular disease in these patients from that found in the majority of persons disabled by peripheral arterial obstructions.

During the next 50 years various aspects of this disease were described in several hundreds of articles from all parts of the world, the investigators noted.

Thromboangiitis obliterans has been described as a specific, idiopathic, recurrent, segmental, inflammatory, obliterative vascular disease involving the medium-sized arteries and veins of the extremities and only rarely the visceral vessels.

The researchers concluded that the term Buerger's disease had best be avoided until more convincing evidence of its existence is presented.

Conduction Tissue

Damage to the vital tissue that conducts the electrical impulse which stimulates the muscle

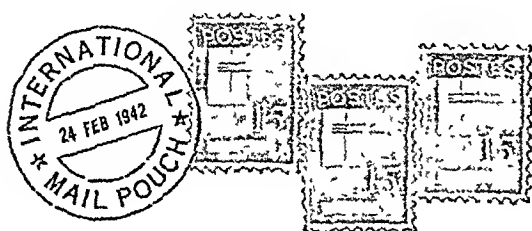

of the two lower chambers of the heart to contract may offer an explanation of some causes of sudden death, according to Dr. George Lumb, Dr. R. S. Shacklett, and Dr. Luther B. Otken, Jr., staff members of the University of Tennessee medical units.

Pathologists are not agreed on whether this vital tissue is composed of nerve or muscle cells, but its importance in the maintenance of life is unquestioned.

The researchers studied the hearts of 260 persons to investigate the diseases which can affect the conduction tissue and produce death

or incapacity of the patient. In a number of instances, the patient died suddenly without significant autopsy findings other than damage to the conduction tissue to explain the suddenness of death.

Pathological lesions found included hardening of the coronary arteries so that there was an inadequate supply of blood to this tissue, inflammation or abscess, hemorrhage or degenerative lesions. The physicians believe that these lesions are perhaps of sufficient magnitude to explain the sudden death of some patients.

The Interns and the Epidemic

When news of 35 deaths and more than 300 people ill in the Dembia Plain came to the Public Health College and Training Center at Gondar, Ethiopia, the college's resources and its first group of interns were mobilized. The symptoms—headache, cough, bloody sputum, muscle pain, and upper respiratory infection—and the investigations of health officers indicated that the outbreak was influenza.

Within 24 hours senior students and graduates were organized into 6 teams, with an intern and 2 senior health officer students on each team. Three teams were assigned to the east side of the Dembia Plain, three to the west side.

The teams traveled from village to village. At each they went first to the chief to explain their mission and to find out how many people had died recently, how many were sick, how long they had been sick, and how many lived in the village. They asked the chief to choose a place where they could see ambulatory patients and they visited the seriously ill. As they saw patients, one man diagnosed, one administered treatment, and one kept records.

The people welcomed the teams because they remembered the malaria epidemic of 7 years ago and feared this sickness was the same disease. But fear and over eagerness sometimes hampered the teams.

Villagers who were well wanted medicine to keep from getting sick. Others wanted only injected medicine. Sometimes faith in medicine was so great that a man adopted the symptoms of the preceding patient. One man asked, "Why do you inject me in the buttock when it's my head that hurts?"

The interns patiently explained that cleanliness and isolation, not medicine, prevented this disease; that medicine was not good for those who were not sick; that different diseases require different medicines; and that an injection is not a cure-all. Often the chiefs as well as the people thought that everyone should be treated.

In the villages, the teams were closely watched. They were asked why they washed their faces in the morning and why they boiled milk, and they were accused of taking the medicine themselves to keep from being sick.

But people wanted them to stay, and often when it was time for a team to depart, there were no mules they could use to continue their journey. Only a stern reminder that the local governors had ordered the villagers to supply them would produce the mules.

The interns also learned to be wary of reports of sickness. Messengers exaggerated the number of the sick to get a team to come to a village. After walking 20 kilometers to find only 1 or 2 patients instead of the 20 or 40 reported, the students learned to make sure a report was verified by a chief.

When the interns had done as much as they could, the teams were recalled to Gondar. They had traveled 1,071 kilometers, visited 57 villages, and treated 2,732 patients.

—ARTHUR C. CURTIS, M.D., former chief, Health and Sanitation Division, U.S. Operations Mission, Ethiopia.

Remunerative homework was found feasible for chronically ill, homebound patients during 2½ years of experience with a group generally considered too incapacitated for vocational activities.

Jobs for the Homebound

MARGARET CLARKE, M.A.

JOBS FOR THE HOMEBOUND is a 5-year demonstration project in vocational rehabilitation operated by the home care department of Montefiore Hospital in New York City. The project is a direct outgrowth of the department's 11 years of experience in providing comprehensive medical care at home to chronically ill, medically indigent patients.

The home care department provides treatment for 85 to 95 patients in the Bronx and upper Manhattan. The patients' illnesses are of such severity that they are unable to attend outpatient clinics and can be maintained at home only with close medical supervision. Care is provided by a medical-social team composed of physicians, social workers, nurses, recreation and art therapists, and physical therapists.

Basic to the philosophy of the home care department is the belief that an indispensable component in medical treatment of the patient is helping him cope with the overwhelming emotional, social, and economic needs which arise with long-term illness. One of the most prevalent of these is the patient's need for meaningful activities appropriate to his physi-

cal condition. Without such activity the patient becomes apathetic and withdrawn, and he may suffer both medically and psychologically.

From the inception of home care, services included a program of diversional activities, and this provided satisfactory occupation for the majority of patients. However, some patients seemed unable to derive satisfaction from leisure-time activities, and from them came a small but very steady stream of requests for "real work." Unfortunately, the community had no facilities for the vocational rehabilitation of homebound patients who were as sick as those found in home care. A survey of rehabilitation facilities for homebound patients in other parts of the country showed that the type of patient seen in home care was consistently excluded from vocational rehabilitation services.

It was decided that the home care patients' persistent requests for work could not be ignored and that investigation of the possibility of their engaging in economically productive activity was warranted. The jobs for the homebound project was initiated on March 1, 1956. The investigation was supported, in part, by a demonstration special project grant from the Office of Vocational Rehabilitation, Department of Health, Education, and Welfare. The New York Chapter of the Arthritis and Rheumatism

Miss Clarke is co-director, with George M. Warner, M.D., home care executive, of the jobs for the homebound project, department of home care, Montefiore Hospital, New York City.

Foundation, the New York Heart Association, and the Nathan Hofheimer Foundation also provided grants for the project.

Objectives

The objectives of jobs for the homebound are:

- To demonstrate the possibilities in vocational rehabilitation for homebound, handicapped individuals with low productive capacities, exploring the potential of such persons for vocational rehabilitation and studying the individual and social effects of vocational rehabilitation on such persons.

- To develop methods for and to determine the cost of providing vocational rehabilitation services to this type of patient.

- Through the information thus obtained, to encourage and facilitate the provision of vocational rehabilitation services to homebound persons presently not considered eligible for these services.

Methods and Organization

Jobs for the homebound functions as an integral part of the home care department, adding vocational rehabilitation to the treatment program of patients for whom this service is indicated. The project began in response to persistent requests from some patients, estimated originally at 30 percent of the total number receiving home care. The idea of working does not occur to many home care patients; generally they are seriously ill persons whose medical conditions are irreversible. Each home care patient who expresses a desire to work and for whom the staff believes work would be beneficial is admitted to the project.

Following admission, the patients are carefully evaluated. Medical evaluations are based on a patient's medical history, results of current physical examination, diagnosis, and an analysis of physical capacities. The psychological and social evaluations include the results of the thematic apperception test and sentence completion test covering attitudes toward illness, a guided interview of work history with emphasis on the meaning of work to the patient, a social data questionnaire, a housing evaluation, and an analysis of patient-family relationships. The

scores and observations on intelligence, interest, skill, and aptitude tests and the education, work experience, and interests revealed in the vocational counseling record are considered in the vocational evaluation of the patient. The project staff then attempts to develop appropriate work plans for the patient.

Patients who in the course of the evaluations, or later, proved to lack ability or incentive to work are carried as inactive participants on the project. This procedure is followed so that the characteristics of the inactive participants can be compared with those of patients who accepted work, and the proportion of the potential candidates for work who subsequently proved unsuitable for work can be ascertained.

Detailed records of work activities are maintained. The patients' reactions to work are continuously observed by home care and project staff members. Medical, psychological, and social effects of work on the patient are formally evaluated yearly.

The co-directors of jobs for the homebound are the home care executive, who is a physician, and the home care supervisor of recreation and art therapy. The professional staff is composed of a vocational rehabilitation specialist and a design specialist. A clinical psychologist, a sociologist, an internist, and a statistician are consultants to the project. The nonprofessional staff consists of a secretary and an assistant workshop foreman who handles stock, pickup, and delivery.

An advisory committee of community leaders in business, industry, and philanthropy who are members of the Montefiore Hospital Board of Directors provides overall guidance for the project and specific assistance in matters pertaining to business and industry.

Characteristics of Patients

Of the 194 patients admitted to home care during a 2½-year period from March 1956 to September 1958, 73 were considered for the project, 34, or 17.5 percent, were admitted, and 39, or 20.1 percent, of those suggested were not admitted (table 1).

Patients were discharged from the project when discharged from home care. Of the 34 patients admitted, 10 were hospitalized during participation and were readmitted to the proj-

Table 1. Reasons by frequency for not admitting 39 home care patients to the project, October 1956–September 1958

Reasons ¹	Number of patients	Percent	Reasons ¹	Number of patients	Percent

¹ Average number of reasons for not admitting patients: 1.5.

ect when readmitted to home care, and 12 were permanently discharged. Seven died, four improved sufficiently to attend outpatient clinics, and one was discharged because he could afford to pay for private medical care.

Of those admitted, 19, or 55.9 percent, were women and 15, or 44.1 percent, were men. (Fifty-seven percent of the patients admitted to home care during the 2½-year period were women.) The median age of the patients was 51.5 years. More than half, 19, were married, 8 were widowed, 1 was divorced, and 6 were single.

Heart disease was by far the most prevalent diagnostic category among patients. Fifteen, or 44.1 percent, of the patients had heart disorders; nine of these had rheumatic heart disease. The others according to diagnostic

categories included pulmonary diseases, four; arthritis, four; diseases of the circulatory system, three; and metabolic diseases, three. The remaining categories with one patient in each were allergies, diseases of the muscular skeletal system, diseases of the central nervous system, cancer, and neurosis.

Three-fourths of the patients had from one to six complicating conditions in addition to the primary diagnosis. Although a few patients were able to leave their homes for short periods daily, the majority were totally home-bound. Eighteen were ambulatory in their homes, 10 ambulated with difficulty, 4 were wheelchair-bound, and 2 were bed-bound; 27 had relatively good use of their hands and, 7 had moderately or severely limited use.

The patient's physician did not recommend

rigid restrictions on activity for the majority of patients with heart disease or for those in the other diagnostic categories. The patient was allowed to set his own limitations on the number of hours he could work and the movements he could make. This flexible approach was possible because the physician visited the patient frequently and was aware of the patient's work and of any impact it had on his medical condition. Also, the vocational worker, in close contact with the physician, could demonstrate any work being considered for a patient

and ascertain the physician's approval or disapproval.

The psychologist found that the patients' emotional attitudes were strongly influenced by their illnesses, and their attitudes toward illness were quite solidly fixed since they had been ill for months or years before admission to the project. The most prevalent emotional response to illness was depression. The most frequent bases for depression were absence of hope for cure, the feeling of being a drain on the family, and inability to continue activities,

such as work and homemaking, which were lifelong criteria of value and acceptability.

The sociologist's data showed that the majority of project participants were from the lower or working classes. Their educational backgrounds were limited, the average number of years of schooling being 8.9. Most had done semiskilled or unskilled work prior to illness, a few were former white collar workers, and none had followed professions. Their median annual earnings prior to illness were \$2,375.

More than one-third of the patients were

born outside the United States, 11 of these in Eastern Europe. Fourteen were Jewish, 6 Italian, 3 Negro, and the others were scattered throughout a number of ethnic and religious groups.

The composition of the group mirrored the ethnic and religious characteristics of the community served by Montefiore Hospital. In this area are predominantly Jewish neighborhoods, predominantly Italian neighborhoods, a few scattered pockets of Irish, and one large traditionally Jewish area increasingly populated

by Negroes and Puerto Ricans. In comparison with the United States population, there was a disproportionately high number of foreign born among the participants.

Work Activities

The most important and dramatic outcome of the project to date is the finding that there is available work which can be performed by patients generally considered to be too incapacitated to work. In a 1-year period 17 such patients put in 3,306 man-hours of productive work and earned from \$1.20 to \$32.88 per week.

There were two types of work for patients in the project: performance of simple industrial processes on jobs subcontracted from local industries; and individualized work activities for patients who were unsuited to industrial homework because of physical disability or because they had special talents and interests. Industrial homework was handled by the vocational rehabilitation specialist and individualized work plans by the design specialist.

Twenty-two patients engaged in work activity extensively, and 11 rejected work on all or the majority of occasions when it was offered. One patient had not yet been offered work because of recentness of admission.

All 22 patients who engaged in work activity worked on at least one industrial homework job. Work plans were also developed for 16 of them by the design specialist. Frequently the work plans originally developed for individual patients subsequently proved applicable to project patients generally.

Industrial Homework

Twenty industrial homework contracts were obtained in the 2½ years. Most of the work consisted of simple, nonskilled operations. Typical jobs included packaging of Christmas tags, assembly of key chains, and sorting and packaging of garment bags and hospital dressings (table 2).

More industrial homework was found than had been expected since a very small and limited "work force" could be offered to prospective employers. While it was not always possible to maintain a steady flow of suitable work

A patient with rheumatoid arthritis works in bed. She staples a display card, homework obtained through an industrial contract.

for all patients, there was always enough work for at least half the patients.

Industrial homework contracts were more readily obtainable from sheltered workshops in the community and from Montefiore Hospital than from industry. All except 4 of the 20 contracts obtained came indirectly from industry through a sheltered workshop or from Montefiore Hospital.

The majority of the contracts were of relatively short duration and involved small amounts of money. The median length of the contracts was 5.5 weeks; the median income per contract was \$23.10. More than half the contracts carried time and production quotas.

No equipment or materials other than those supplied by the manufacturer were necessary for the majority of the contracts. It was found impracticable to obtain or devise special equipment to compensate for a patient's disability; the expenditure of time and money which would

have been necessary were not justified for the short, low-paying contracts.

The ability and skill required of the workers were modest. Only two contracts required work with a high degree of finger dexterity and nearly half required only moderate finger and manual dexterity. Not all jobs were appropriate for all patients. The median number of patients for whom a contract was suitable was 5.5.

The production records of 17 patients who performed industrial homework for all or part of a 1-year period were analyzed. They worked a median of 10.25 hours per week or approximately 2 hours per day, and the number of hours was markedly influenced by the type of work performed. For example, one contract, inserting lacing through a display card, was so nontaxing that patients who customarily worked 2 to 3 hours a day worked at it for 6 to 8 hours.

In accordance with regulations of the U.S. Department of Labor, patients were paid at piece rates comparable to those paid nonhandicapped workers performing similar jobs. Patients who failed to earn an average of 40 cents an hour while working at piece rate were subsidized up to this amount, the subminimum rate approved for the project by the Department of Labor. The median earnings per patient were \$4.64 per week, and the median subsidy per patient was \$1.02 per week or 8 cents per hour. Approximately half of the patients consistently required fairly high subsidy; the other half, only small amounts of subsidy and only on occasional jobs.

Although all the patients were seriously ill, the range of capacity for economic productivity among them was considerable. At the top level was Mrs. A. T., 52, with rheumatic heart disease. During a typical 1-month period, she worked at several different industrial jobs for a total of 53 hours, earned \$27, and required no subsidy. On the lowest level was Mr. S. R., 41, with multiple sclerosis. In 1 month he worked a total of 20 hours, earned \$8, of which \$5.60 was subsidy.

The work performed for a sheltered workshop demonstrated the advantages in the sharing of contracts by workshops and homebound programs. The increase in the size of the "labor force" and the diversified skills made

available when workshop and homebound clients joined forces enabled the combined group to fulfill larger and more complex contracts than either could do alone.

The contracts with Montefiore Hospital for machine sewing of surgical supplies and packaging of cotton and gauze dressings demonstrated a work plan widely applicable for the disabled. This type of work is required by hospitals throughout the country and should, therefore, be available to sheltered workshops and homebound programs nationwide.

Individual Work Plans

Special work plans were developed by the design specialist for patients who found industrial processes difficult because of impairment of manual dexterity and for those who had special talents and skills and preferred more challenging activity than industrial homework.

In developing work plans for severely disabled patients, the design specialist geared her efforts to the problems presented by two women with rheumatoid arthritis. The movement of fingers, wrists, and arms was so drastically limited for these women that they represented the minimum manual ability in the group. It was assumed that any work plan that proved physically possible for them would be widely applicable among others who found industrial processes difficult.

The first work plan developed for the arthritis patients was based on the vocational background of the women concerned. Both had been sewing machine operators prior to illness and were anxious to resume this type of work. They were found able to handle straight machine sewing, their knowledge of the process being so firmly ingrained that they were able to adapt the process to their manual limitations.

The design specialist found that Montefiore Hospital manufactured for its own use glove covers, syringe covers, binders, and other surgical supplies which required simple machine sewing. The patients were tested on manufacture of these items and proved able to produce them satisfactorily. The project then contracted with the hospital to supply a portion of its requirements for surgical supplies. The job was transferred to the industrial homework

A patient with bronchial asthma binds medical journals. Formerly a skilled carpenter, he works at bookbinding approximately 4 hours a day.

category when it proved appropriate for five women in addition to the arthritis patients.

The second work plan initiated for severely disabled patients was the development of salable articles so designed that their production required only movements which these patients were able to make. Again the arthritis patients were the guinea pigs.

The first step in devising a product was to have the arthritis patients experiment with the process to make sure that they could carry out each of the required movements. A sample of the product was then made and submitted to the buyers of representative department stores and gift shops in New York City. Products were modified or discarded on the basis of the buyers' opinions. Products with which the design specialist experimented included block-printed and silk-screened napkins, place mats, greeting cards, hand-stenciled glasses and bottles, and ceramic tile ashtrays.

By September 1958 six patients were producing for sale machine-sewn tablecloths and ceramic ashtrays. These articles were being marketed through Free Will, a distribution agency sponsored by the New York State Division of Vocational Rehabilitation. Numerous other products were still in the experimental stage.

The design specialist developed four specialized work plans for patients who preferred more challenging work than the industrial jobs available on the project. One such patient was Mr. C. K., a former carpenter, with severe pulmonary emphysema. He had been enormously proud of his ability to design and construct fine furniture and was bored with and somewhat contemptuous of the nonskilled industrial homework. The design specialist helped this patient develop an original method of bookbinding at home. A sizable amount of work was obtained for him in the binding of professional journals for physicians in the hospital.

Another patient, a young man who had had diabetes for most of his life, was trained in jewelry making. For three women who were highly skilled in needlework a contract for sewing of a millinery decoration was obtained. Three women who did exceptionally fine knitting were helped to market their work through a specialty shop.

Impact of Work on Patients

By September 1958, 13 patients had completed a year or more of participation in the jobs for the homebound project. Eight accepted work on the majority of occasions when it was offered, and five consistently refused work.

The data on the impact of work on the eight patients who accepted work should be interpreted most cautiously. The material was obtained from both formal evaluation procedures and the informal observations which physicians, social workers, and others made in the course of routine contacts with the patients.

The strongest impact of work appeared to be psychological. Some degree of improvement was observed in all eight patients who worked for a year or more. The most frequently reported psychological effects were reduction of depression and increased feelings of adequacy.

Improvement was seen in the attitude of each of the eight patients toward his illness rather than in measurable clinical improvement. Changes included less preoccupation with limitations and relinquishment of unrealistic plans for the future. In only one instance did work appear to bear some relationship to a symptomatic change in the patient.

Work was reported to have had an impact on patient-family relationships of five patients who worked for a year or more; no impact in this area was reported from the other three. Though for all five, some improvement in family-patient relationships was reported, in two, family relationships were also disrupted in some respect when the patient worked. For example, one patient's mother resented her son's earning money because it threatened her need to keep him dependent upon her.

Responses to work activities appeared to be conditioned by the relationship to home care of six patients; no such influence was noted for the other two. These six were observed to enjoy the attention of the staff and to seek their approval. In at least one instance a significant element in the patient's motivation for work seemed to be the desire to comply with what the patient believed to be the staff's wishes.

Twenty-two, or 11.3 percent of the patients admitted to home care, accepted work on all or the majority of occasions when it was offered. The fact that 11 percent of a group of severely incapacitated patients proved capable of economically productive activity is significant as an indication of the untapped human resources available among severely disabled homebound persons in the country as a whole.

Certain differences were observed in the characteristics of the patients participating in the project and the home care group as a whole. Project participants were younger; their median age was 51.5 years; for home care, it was 60.1 years. There was an indication that project participants were slightly less ill than home care patients generally; the average number of admissions to the hospital for project patients was 1.1, for home care patients, 1.6.

The 11 patients rejecting work differed from the project group as a whole in several respects. In this group there were more women (72 per-

cent) than in the project group as a whole (55.9 percent), and the median age was older (54.5 years) than the 51.5 median age of the total project group. Also, the median number of years of education was lower (7.3) than for all patients (8.9). There appeared to be no significant differences in the diagnostic categories of the patients who did not accept work and the total project group.

Two reasons were most frequently cited by patients for not working; they did not like the type of work offered, finding it dull, uninteresting, or beneath them, and they felt too ill to work. On the other hand, the staff opinion concerning the majority of these patients was that their refusal to work was on an emotional basis. For example, some patients were too preoccupied with illness to concentrate on work; others had not accepted the limitations of their illnesses sufficiently to be satisfied with the sedentary work of which they were capable.

Costs and Applicability

Experimentation with more than 25 different work plans indicated possibilities for numerous types of work programs of varying costs for the kind of patient found in home care. Program costs will depend on the number of rehabilitation services such as vocational counseling and testing offered and the degree to which the program attempted to fit each patient into an individually suitable job.

Examples of homework programs of varying costs which can be incorporated in medical home care programs and can serve 20 patients follow.

- Minimal cost program confined to one steady contract such as the jobs for the homebound contract with Montefiore Hospital for the packaging of hospital dressings.

Staff (a half-time program supervisor-instructor who would supervise the program and instruct patients in work processes, a full-time pickup and delivery man, a half-time secretary)-----	\$8,100
Travel to patients' homes-----	280
Office supplies-----	95
Occupational licenses-----	25
Overhead (15 percent of direct costs)-----	1,500
Total -----	\$10,000

• Medium cost program providing diversified industrial contracts sought from local firms.

Staff (a full-time vocational rehabilitation specialist who would supervise the program, solicit industrial contracts, and instruct patients in work processes; a full-time pickup and delivery man; a half-time secretary)-----	\$11,390
Travel to patients' homes-----	360
Travel for solicitation of work-----	300
Office supplies-----	150
Occupational licenses-----	25
Work equipment-----	525
Overhead (15 percent of direct costs)-----	2,250
Total -----	\$15,000

• Relatively expensive program incorporating all service features of jobs for the homebound project including product development and diversified industrial homework contracts.

Staff (a full-time vocational rehabilitation specialist who would supervise the program and be responsible for all industrial homework and for vocational testing and counseling, a design specialist hired as a consultant, a full-time pickup and delivery man, a half-time secretary)-----	\$13,804
Office supplies-----	175
Travel to patients' homes-----	396
Travel for solicitation of work and marketing of products-----	300
Occupational licenses-----	25
Work equipment for patients-----	600
Overhead (15 percent of direct costs)-----	2,700
Total -----	\$18,000

Summary

Jobs for the homebound is a 5-year project concerned with investigating the vocational potential of homebound, chronically ill patients who are generally considered to be too incapacitated for vocational rehabilitation services. The project has been in operation for 2½ years as an integral part of the home care department.

It was found that there was available work which could be performed by seriously ill, homebound patients. In 1 year the project patients put in 3,306 man-hours of productive work and earned from \$1.20 to \$32.88 per week. The patients who worked constituted 11 percent of the patients admitted to home care. This figure is highly significant when it is considered that among the chronically ill, homebound persons throughout the Nation a similar portion also has a potential for productivity.

All patients who worked for a year or longer were reported to have experienced some degree of psychological improvement, primarily reduction of depression. All patients also experienced some degree of improvement in their attitudes toward illness, although it was frequently difficult to tell whether the improvement observed was due to work alone or to the combination of home care services and work.

Experimentation with many different types of work plans indicated that homework programs for the kind of patient found on home care could be operated at reasonable costs, ranging from \$10,000 to \$18,000 per year for 20 home care patients.

Arnold Appointed Assistant Surgeon General

Dr. Richard C. Arnold, chief of the heart disease control program of the Public Health Service for the past 3 years, has been appointed Assistant Surgeon General for Personnel and Training. He succeeds Dr. Otis L. Anderson, who retired on June 30, 1959, after 30 years' service in the commissioned corps.

A career officer of the Service's commissioned corps, Dr. Arnold previously served 6 years as chief of the Technical Services Branch

of the National Heart Institute, after having directed syphilis research at the Venereal Disease Research Laboratory in Staten Island, N.Y., for 13 years. His initial posts with the Service, on completion of his professional studies at the University of Louisville in 1930, were in hospitals in New Orleans and San Francisco in venereal disease work. Dr. Arnold's grade is equivalent to that of brigadier general.

Trends in Occupational Health Programs in State and Local Units

VICTORIA M. TRASKO, A.B., and CHARLES D. YAFFE, M.S.

THE YEAR 1959 has been outstanding in the development of occupational health programs in State and local governments. Both the number of units and personnel reached a new high, exceeding for the first time the 1950 peak. Presently, 484 professional personnel staff 76 occupational health units located in 40 States, including Hawaii, the District of Columbia, and Puerto Rico, and in 33 local health departments. Three of the State programs (New York, Massachusetts, and Illinois) are in departments of labor, and the rest are in health departments. The growth pattern, however, has not been uniform. Nor has the personnel rise been commensurate with the increased responsibilities of State and local occupational health agencies. Frequently, additional staff has been largely absorbed by the newer industrial health problems associated with air pollution and radiation.

Personnel

Growth trends are illustrated by a series of charts based on directories of governmental industrial hygiene personnel issued annually since 1942 by the Occupational Health Branch. Figure 1 shows that the growth in the number

of personnel in local units has been slow but steady. In 1942 they accounted for 10 percent of total staffs, and in 1959, for 20 percent. Total State and local staffs fluctuated from a low of 247 members in 1942 to a high of 425 in 1950, then dropped to a low of 360 in 1957, and rose sharply to the present new high of 484 persons.

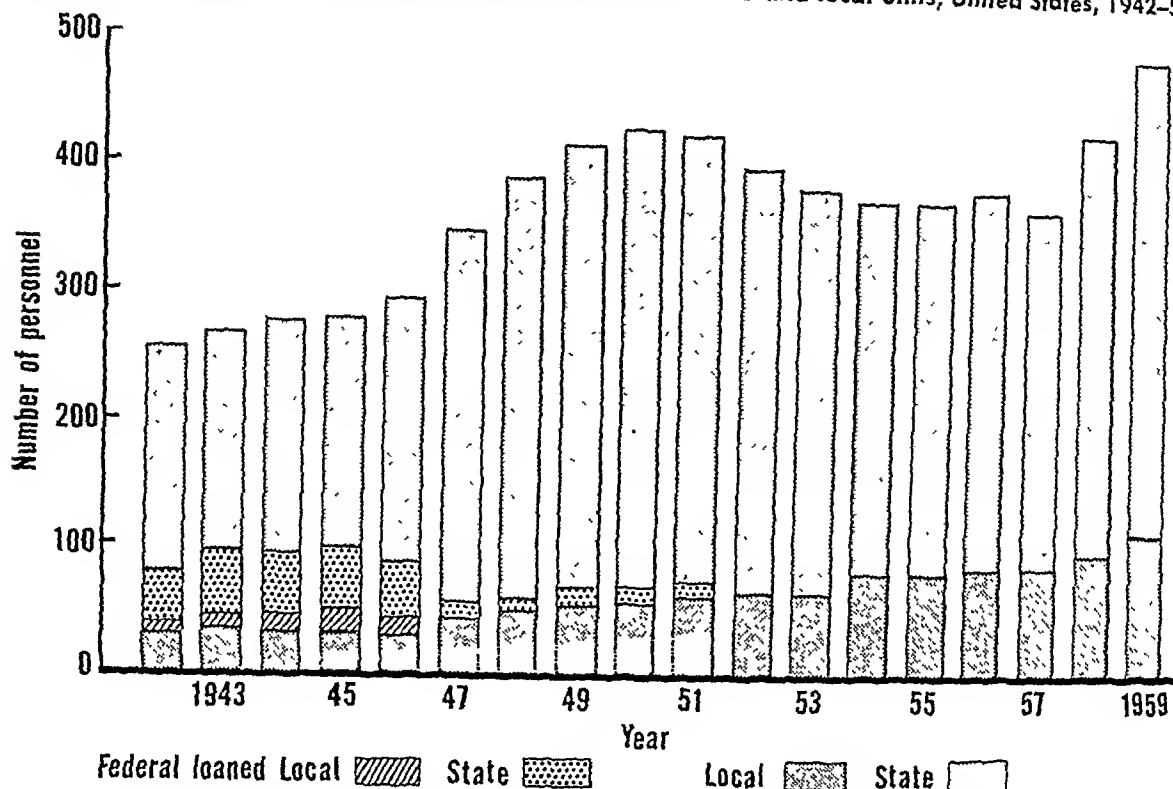

State programs developed most rapidly immediately following the passage of the Social Security Act in 1935, when funds were made available for expansion of public health programs, including industrial hygiene. National defense activities and World War II accelerated the establishment of additional units so that by 1942 there were programs in 36 States and 7 local health departments with a total of 247 professional personnel, including 44 on loan from the Federal Government.

The impetus that led to the 1950 peak in personnel was the designation of Federal grant-in-aid funds for industrial hygiene. Spread over the 3-year period 1947 to 1950, these funds also helped to offset the withdrawal in 1946 of Federal personnel on loan by providing monies for recruitment of trained industrial hygiene personnel being released from military service.

The subsequent discontinuance of earmarked funds and the general decrease in State appropriations resulted in a retrogression in occupational health activity, reflected not only in the loss of personnel but also in the discontinuance of some programs. Part of this decline was also due to the low salary scales then prevailing in government agencies and part to the absorp-

Miss Trasko is program adviser, and Mr. Yaffe, sanitary engineer director, Occupational Health Branch, Bureau of State Services, Public Health Service, Cincinnati, Ohio. The article is based on a paper presented at the Industrial Health Conference in Chicago on April 27, 1959.

Figure 1. Number of occupational health personnel in State and local units, United States, 1942-59

tion of personnel by industry, the armed services, and other agencies that were beginning to employ industrial hygienists at a rapid rate.

All programs were not affected to the same degree. In some instances, their financial situation was stabilized through the appropriation of State air pollution funds for factfinding studies in which the industrial hygiene units cooperated extensively. Otherwise, the setback would have been more serious. It took 8 years to reach the peak in staffs achieved in 1950, a level which was exceeded only this year.

Viewing the long-term growth in staffs, we find that the number of persons in State and local units, exclusive of Federal personnel on loan, has more than doubled since 1942. The growth has been erratic, but the sharp increase from 1957 to 1959 appears indicative of a new upward trend. However, forecasting future growth on the basis of the past is not simple. The fractionation of industrial hygiene programs into specialties, including radiation and air pollution, or the combining of these specialties under one administrative head can readily cause fluctuations in numbers of personnel both

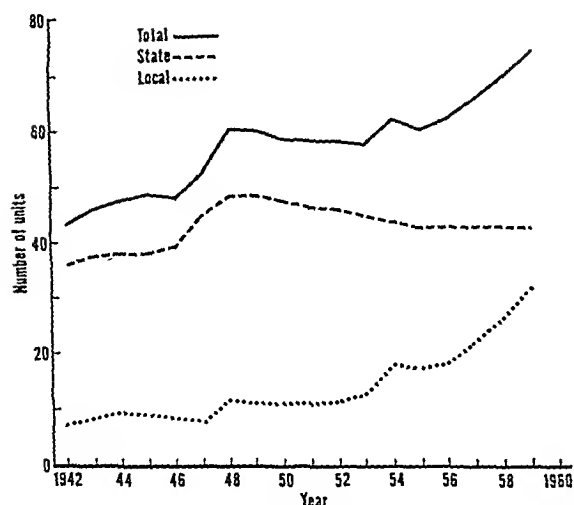

at an individual State as well as the national level.

However, a closer look at the nature of the increase from 1957 to 1959 discloses that 22 State and 18 local units, of which 12 are new, have increased their staffs from 1 to 17 persons, or an aggregate of 137 persons. Six State programs account for one-half of the total staff increases during the period.

In contrast, only seven State and three local programs showed a net decline in personnel. The maximum loss in any unit was 2 persons, and the total loss was 13. Twenty-six units now functioning showed no change.

Today's comeback in personnel is actually greater than the gross numbers show. The present counts are based strictly on information received for annual directories of occupational health personnel in government, and are not all inclusive. For example, they exclude industrial hygienists employed by industrial commissions in at least four States. Likewise, certain local health departments providing limited occupational health services may have escaped attention.

Figure 2. Number of occupational health units, United States, 1942-59

Units

Figure 2 depicts trends in the number of units functioning since 1942. The high point in the number of State units occurred from 1948 to 1950, when all but two States provided occupational health services on at least a limited basis.

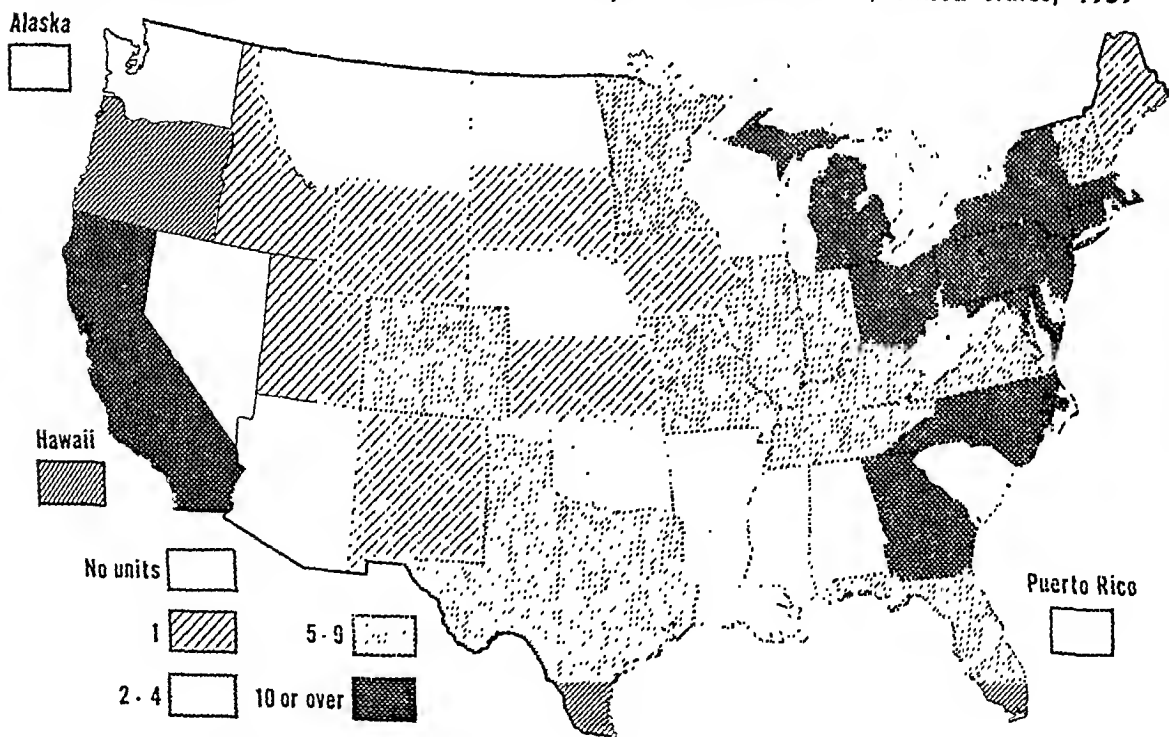

As a result of loss of funds and postwar reduction in industrial activity, a number of States discontinued programs. Today 10 States including Alaska still do not have occupational health programs in either health or labor departments.

On the other hand, local units have shown a gradual upward trend, especially for the last 10 years. In contrast with 7 units in 4 States in 1942, today 33 units are found in 15 States. The effects of vigorous State efforts to encourage the establishment of local occupational health units are evident in California, which has about one-half of these 33 units. This trend for local health departments to assume responsibility in occupational health is highly promising. Local health departments occupy a strategic position in promoting community health in all its aspects.

Size of Units

Although the number of State units has remained stable during recent years, the number of staff members has been increasing since a low

Figure 3. Number of personnel in State occupational health units, United States, 1959

point in 1954. Significantly, at present only 21 percent of the units employ two to four persons, as compared with 48 percent 3 years ago, and units with five or more persons today represent 58 percent of the total as compared with 40 percent in 1947.

There has been no significant pattern for one-man units, although the total number has increased slightly during the past 3 years. The eight units currently in this category are in States which, generally, are not highly industrialized (fig. 3).

With the exception of California, State units with 10 or more persons are located in the eastern part of the country. Units with five to nine persons are scattered, whereas the units with smaller staffs are concentrated chiefly west of the Mississippi River.

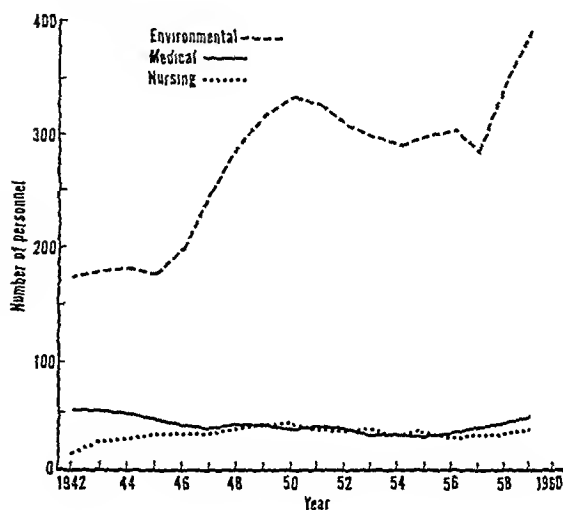

Professional Staffing Patterns

When State and local governments first engaged in occupational health, their primary objectives were improvement of the working environment and elimination of health hazards. Over the years their programs have continued to emphasize environmental studies, with such activities accounting for 70 to 90 percent of all direct services to industry. The need for balanced medical-environmental programs has long been recognized, but their development has been hampered by lack of appropriate personnel and, in some instances, lack of sufficient motivation.

Figure 4 shows clearly the great differential between environmental and medical and nursing personnel. Environmental personnel, consisting of engineers, industrial hygienists, and chemists, accounted for about 70 percent of total staffs during the war years, 1942-46. For the past 10 years, the percentage has hovered about 80.

The present low level of medical personnel in State and local units should not be compared with that during the war period, when about one-half of the physicians were on assignment from the Public Health Service. These units have consistently experienced great difficulty in recruiting and keeping medical personnel. Some gain in industrial nursing consultants was made during the war years. Since then,

Figure 4. Number of environmental, medical, and nursing personnel in State and local occupational health units, United States, 1942-59

their number has remained comparatively the same.

Trends in Program Content

To obtain information on program content, a limited survey was conducted among directors of 12 State and 2 local occupational health units. These units, widely scattered geographically, employ from 5 to more than 50 professional personnel, with an average of 11. While they do not necessarily represent an accurate sample of the entire country, their replies are significant.

In discussing changes of program emphasis, 5 of the 14 directors mentioned increased attention to radiation problems, 2 to air pollution, 1 to silicosis studies and research, and 1 to labeling activities. In five units, the change is toward extending direct services to more establishments as well as to more diverse types of industries. Three directors are actively promoting the establishment of occupational health services in local health departments, and one is expanding appreciably its informational and educational activities.

In considering activities requiring more emphasis, seven directors agreed on the need for more comprehensive or improved coverage of industrial establishments. Four directors men-

tioned the necessity for better educational and informational services to industry, and two expressed a need for closer and better working relationships with industry, the medical profession, and other groups on employee health services. The need for more and better trained personnel in local health departments was also mentioned. Only two directors expressed a need for more emphasis on radiation and one, on air pollution, possibly because most of the other units were already involved. Two directors believed their programs are adequately balanced for the present.

The directors' estimates of total staff time spent on different components of their programs showed a remarkable agreement. For example, 12 of the 14 directors estimated that at least 50 percent of total professional staff time is spent on field investigations and services. The range for the 14 units is 33 to 92 percent, with a median of 67 percent.

About 15 percent of the total staff time is devoted to laboratory services and developmental research, 15 percent to teaching and health education activities, and about 2 percent to civil defense. Individual estimates for civil defense range from 1 to 7 percent. Six of the directors reported that employee health services for State employees required from 1 to 25 percent of staff time, giving a median value of 4 percent.

Eleven of the fourteen directors reported at least 70 percent of staff time spent in the field is devoted to investigation of occupational hazards. The range was 33 to 95 percent, with a median of 81 percent. This indicates that most of these units still concentrate their efforts in the traditional areas of industrial hygiene.

Wide variations were found in the percentage of self-initiated and requested field visits. One unit reported that 100 percent of its field work results from requests; another that requests account for only 6 percent of its field services. For all 14 units the median value for self-initiated field visits is 62.5 percent.

In the directors' opinions, dusts and ionizing radiation constitute the leading problem areas of occupational health, with solvents and gases next in order. Also mentioned were implant health services and noise. The problem areas

receiving most attention are ranked in the following table.

Problem area	Rank			Total
	1st	2d	3d	
Dusts-----	4	2	3	9
Ionizing radiation-----	5	1	2	8
Solvents-----	2	3	1	6
Gases-----	1	2	3	6
Implant health services---	0	2	2	4
Noise-----	0	1	1	2

Two of the directors of State units would not attempt to separate the promotion of implant health services from investigations of occupational hazards. They stated that all personnel regularly attempt to promote improved health services whenever they visit industry for any purpose. The others show a range from 1 to 20 percent, with 8 percent being typical, for total field time spent on this activity.

The occupational aspects of radiation have continued to increase in recent years. While they have added to the total burden of the occupational health unit, no attempt has been made to segregate them as separate items in terms of staff time, since they are considered part of the broad program to control hazards associated with the working environment.

Because of the training and experience of staff members, many occupational health units have also been given overall responsibilities for radiation problems, community as well as occupational. Among the units reporting in this limited survey, an average of about 4 percent of field time is being spent on nonoccupational radiation problems. However, wide variations in this figure may be expected, depending on the extent of activity and size of the unit.

For example, 17 occupational health units maintain fallout stations and monitor air and precipitation for radioactive fallout as participants in the Public Health Service radiation surveillance network program. Many of their personnel have gone on temporary active duty with the Public Health Service to monitor fallout in connection with weapons testing in Nevada. Likewise, many of these personnel are working in radiation instrument phases of civil defense courses and in monitoring instruction. In one State 18 man-days were spent 1 year in instruction alone.

In the larger units these additional duties usually do not represent a heavy burden. How-

ever, smaller units are likely to find these activities taking a much greater proportion of their time, and at the expense of routine work. Many units have helped to draft regulations for the control of radiation sources. Preparing these regulations may require as many man-days for South Dakota with its one-man State unit as for Michigan with a staff of more than 20. Similarly, the time requirements for operating a fallout monitoring station are the same, regardless of staff size. As more and more regulations on radiation are passed, the responsibility and workload of these units will be increased, especially in the registration of users of radioactive materials or operators of X-ray equipment.

The reporting units indicated that air pollution work in general accounts for about 5 percent of field time, although one State estimates 25 percent of its time on this activity. Here, too, however, it is difficult to obtain a representative figure. Because of the extensive experience of occupational health agencies with industrial emissions, these units have frequently been given responsibility for community air pollution. The line between the occupational and community aspects of air pollution sometimes blurs, making it difficult to separate the time spent on each. Because so much air pollution activity is interrelated with industrial hygiene, many occupational health units consider it as part of their routine investigations rather than a separate item.

At present responsibility for air pollution control rests primarily with occupational health units, as reflected by the 1958 Directory of Governmental Air Pollution Agencies (1). Of the 41 State agencies listed, 30 are in occupational health units and 11 are in other units of departments of health. In New York, the State Division of Industrial Hygiene, Department of Labor, shares the responsibility with the New York State Department of Health, and does the sampling of industrial effluents.

Occupational health units also participate in the Public Health Service's national air sampling network. There are 115 air sampling stations throughout the country, including 19 operated by State and local occupational health units.

Air pollution control is primarily a local

problem, with regulatory authority frequently vested in local boards of air pollution control or in smoke abatement agencies, and technical assistance is often provided by local occupational health units. If control authorities are not set up, the burden of handling air pollution problems usually falls on the occupational health unit.

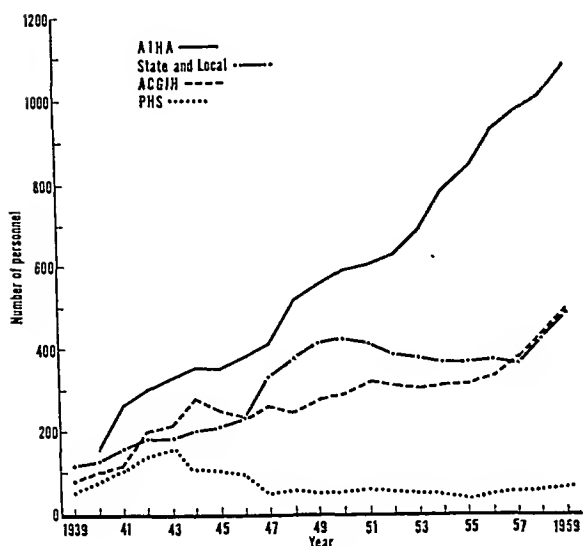

Other Trends

Some State units are stepping up their efforts to encourage the participation of local health departments in occupational health. The growth in number of local units has been mentioned. In addition, there appears to be somewhat greater use of local health department personnel in field activities such as in followup work and in routinely accompanying State personnel on plant visits. The extent to which the States enlist such services varies considerably. This variation may be due partly to the differences in the degree of development of local health services and partly to the lack of conviction in some States of the desirability of utilizing local personnel with limited training in industrial hygiene.

Interest in additional training for personnel is being stimulated by availability of more training facilities and Federal grants and fellowships. Our limited survey showed that 22 persons employed in the 14 units have received a year or more of graduate training during the past 5 years. Some 200 courses of at least 2 weeks' duration have been attended by staff members of these units. Approximately half of these courses have dealt with ionizing radiation. About two-thirds of the remainder have been in industrial hygiene, and the rest were air pollution courses. Likewise, the extent to which State and local personnel participate in training courses for other groups, such as local health department personnel, and in teaching industrial hygiene in schools and universities has also been steadily increasing.

Over the years a handicap to the development of State and local units has been personnel losses and turnover. Since 1942, by actual count of names in the annual directories of government industrial hygiene personnel, 1,470 different persons have been employed at one time or

Figure 5. Occupational health personnel in professional organizations, State and local units, and the Public Health Service, United States, 1939-59

NOTE: AIHA=members of American Industrial Hygiene Association. ACGIH=members of American Conference of Governmental Industrial Hygienists. PHS=professional staff of the Occupational Health Branch, Public Health Service, including personnel on loan to State and local units.

another by State and local units and the Occupational Health Branch of the Public Health Service. Subtraction of the number of persons on current staffs reveals that more than 900, many with excellent training and experience, have left official occupational health agencies for one reason or another during the past 18 years. However, many have remained in the industrial hygiene field, employed by industry, universities, the armed services, and other groups.

In the absence of data on employment of industrial hygienists outside government, the annual membership of the American Conference of Governmental Industrial Hygienists and the American Industrial Hygiene Association and personnel in the State and local units, starting with 1939, have been plotted in figure 5.

The rapidity of growth of the American Industrial Hygiene Association indicates the extent to which industry is employing industrial hygienists. Although a number of association members are in government, the curve provides

a rough idea of the number of industrial hygiene personnel associated with nongovernment work.

If personnel requirements expressed by directors of State and local units interviewed in this survey are typical of present national needs, full-time occupational health staffs in State and local units should number at least 1,000. However, even this figure, more than double the present number, is a ratio of only 1 person for every 65,000 workers in the labor force.

Finally, there is definite evidence of increased financial support for some State and local programs from their own departments. This support was variously attributed. Eleven of the fourteen directors interviewed consider their engineering studies and services to industry their best selling points. Some mentioned specifically the quality and objectiveness of their studies; others, the high professional caliber of work performance which has caused industry to accept government services. Radiation and air pollution activities were mentioned as being popular and helpful in getting appropriations. One director credited his program's financial stimulus to a Statewide conference on occupational health sponsored by the Governor's Council; another to special training courses held for industrial personnel.

Other selling points specified were dissemination of information on industrial health through periodic bulletins and short pamphlets and working with professional organizations and medical groups to bring about a better understanding of industrial health and the contribution of government programs.

One director credits the effective support his program receives to excellent administration by his health commissioner, cooperation with other branches and agencies, and willingness to accept broader responsibilities. This point, the importance of being willing to accept broader responsibilities, cannot be overemphasized in a field with as infinite opportunities for service as occupational health.

Conclusion

Recent growth trends in State and local occupational health units hold promise that the occupational health picture may be improving.

However, these changes mark only a beginning, since occupational health activities in general have long been grossly underdeveloped. Today's record staffs fall at least 50 percent short of the number needed to do a halfway adequate job. It is particularly encouraging to note the increase in local units, and it is hoped that this

tendency and the strengthening of all official agency staffs will continue.

Encephalomyelitis in Horses

An early classic clinical description of what appears to have been western encephalomyelitis in horses has been found by Dr. Roy F. Feemster in a footnote to the section on poliomyelitis in the 1909 annual report of the Massachusetts State Board of Health. The footnote consisted of a letter from a practicing veterinarian in Minnesota describing a paralytic disease in horses, and formed a part of a discussion on sickness in animals and poliomyelitis in man. At that time, investigators were looking for evidence of a relationship between paralytic disease in animals and in man. The veterinarian may have been led to write the letter because of a high incidence of poliomyelitis in both Minnesota and Massachusetts in 1909. It is recognized now that the veterinarian probably was describing cases of western equine encephalomyelitis.

The first clinical description of encephalomyelitis in horses may have been made as early as 1831 following an outbreak of paralytic disease in Massachusetts. Dr. Alfred Large described a similar disease on Long Island in 1867.

The entire footnote, including the letter from Dr. C. S. Shore, Lake City, Minn., follows:

"The following letter, which reached the board through the State Board of Health of Minnesota, is of possible interest in this connection:

"In my veterinary practice during the past 5 or 6 years, I have found a disease appearing among

1- and 2-year-old colts that shows a line of symptoms corresponding very closely to anterior poliomyelitis of children. I have had from 5 to 10 cases a year during this time, the cases always occurring during the summer months, and the majority of them during the month of August. The affected colts are usually found in the pasture, unable to stand. The owner sometimes will notice an unsteady gait for 24 hours before entire loss of motion occurs. At first, these colts have a rise of temperature, ranging from 103° to 104° F.; pulse and respiration accelerated; animal sweats profusely; appetite remains fairly good, but there is some trouble noticed in swallowing, especially water; slight derangement of the bowels, tending toward constipation; more or less tympanitis present; retention of urine, for a few hours at least; head drawn back so the end of the nose tends to assume a position somewhat on a line with the neck. The death loss is less than 10 percent, but in those that do recover, the market value is depreciated to a very great extent because of the faulty gait the animal assumes after an attack of this disease, due to atrophy and contraction of certain muscles or certain groups of muscles. It seems that the flexor muscles of the limbs especially are more often affected than the extensor, and in almost all the cases some of these deformities are likely to remain permanent. The flexors of the limbs are liable to contract and cause volar flexion of the fetlock. The elevators of the head are also likely to become affected so as to cause the head to have a poky appearance; that is, it is carried out from the body.

"After one of these attacks the colt will remain down from 1 to 3 weeks, and will then continue to improve for a period of 1 year, but seldom, if ever, makes a complete recovery."

Dr. Feemster is director of the division of communicable diseases, Massachusetts Department of Public Health—CARL C. DAUER, M.D., medical adviser, National Office of Vital Statistics.

*By Arthur S. Flemming, Secretary of Health,
Education, and Welfare, June 30, 1959*

Wax Used for Milk and Food Containers

I AM INFORMED that both the Food and Drug Administration and the Public Health Service are receiving many inquiries about possible cancer-producing agents in wax used for milk cartons and other food containers.

I think we should try to clarify the situation with respect to these waxes.

During the latter part of 1956, Dr. W. C. Hueper, of the Public Health Service, arranged with the Milk Industry Foundation to collect waxes used by dairies for the impregnation of milk containers. Several months later the foundation assembled about 40 waxes for further chemical and biological analysis and sent them to the National Cancer Institute. In June 1957, 24 of these waxes were sent for study to Dr. Philippe Shubik, division of chemistry, Chicago Medical School. Dr. Hueper provided Dr. Shubik with suggestions for the work and data on the economic, chemical, and biological aspects of dairy waxes. A representative sample of each of these waxes was retained by the National Cancer Institute's Environmental Cancer Section of which Dr. Hueper is chief.

In the fall of 1957, Dr. Hueper received a report from Dr. Shubik on results of preliminary tests of the 24 waxes. The studies were performed by Dr. William Lijinsky, an associate of Dr. Shubik's. It was demonstrated in these studies that one of the waxes contained a known carcinogen (cancer-producing agent), 1,2,5,6-dibenzanthracene. Three additional waxes were suspected but no carcinogen could be identified. It should be noted that while this compound has produced cancer in laboratory animals, 1,2,5,6-dibenzanthracene has not been shown to produce cancer in man.

A report of the results of this investigation was communicated to Ernest Kellogg, secretary of the Milk Industry Foundation. As a result, Mr. Kellogg asked the American Petroleum Institute for assistance in investigating the problem.

Dairy industry representatives also met with Public Health Service milk and food personnel to map out a program to assure that the waxes used were free from impurities. In November 1957, the American Petroleum Institute made available \$100,000 a year for 5 years to support additional studies by Dr. Shubik (Dr. Shubik has indicated that the results will be published as the studies are completed).

Accordingly, Dr. Shubik was supplied an additional sample of 26 representative waxes by the petroleum industry. By the time these new samples were received, Dr. Shubik had improved his analytical techniques to the point where he could identify as little as 1 part of 1,2,5,6-dibenzanthracene in one-half billion parts of wax. In the earlier experiments, sensitivity was 1 part of 1,2,5,6-dibenzanthracene in 1 million parts of wax. With the high sensitivity of the new techniques, no dibenzanthracene has been found in any of the 26 samples.

Meanwhile, in 1958, samples of the 24 waxes sent to Dr. Shubik by Dr. Hueper in 1957 also were sent to Dr. Paul Kotin, associate professor of pathology at the University of Southern California. The major results of this study, made by Falk, Kotin, and Miller, were published in the April 25, 1959, issue of a British scientific journal, *Nature*, pp. 1184-85.

The Kotin investigations confirmed the Shubik findings that one wax contained between

0.5 and 1.0 micrograms per gram of 1,2,5,6-dibenzanthracene. The Kotin investigations demonstrated, in addition, that 1,2,5,6-dibenzanthracene added to dairy waxes for experimental purposes was extracted from thin layers of wax by milk.

The results of these studies have been reviewed by scientists of both the Public Health Service and the Food and Drug Administration. I am advised that the findings are not final, but no indications of a health hazard have been found. The Food and Drug Administration advises there is at present no basis for action concerning these waxes under the Food, Drug, and Cosmetic Act.

The scientists are also agreed that more information is needed. The Food and Drug Administration plans a study of these waxes in its own laboratories if its appropriation for 1960 as now approved by both House and Senate is finally enacted. The Public Health Service also plans to support further studies and to provide technical assistance to the industry in its control program.

It should be pointed out that the new food additives amendment to the Federal Food, Drug, and Cosmetic Act covers the safety of food container materials which incidentally contaminate food, just as it covers additives for direct addition to food.

Permits for Nuclear Waste Disposition

Pennsylvania's Sanitary Water Board has announced seven permits for the discharge of radioactive wastes into streams. Radioactivity of the discharged material is limited to minute levels, and all safeguards are taken to assure that these levels are trivial or insignificant to public health.

The first of these permits, issued November 1, 1957, was for wastes discharged by the Duquesne Light Co. of Pittsburgh into the Ohio River from Shippingport. (*Public Health Reports*, October 1958, pp. 895-901.) Others issued in 1958 were:

March 24. Research laboratory of Mellon Institute of Industrial Research in Penn Township, Westmoreland County, discharging into Bushy Run, tributary of the Monongahela River and two creeks.

March 26. (Amended August 21, 1958.) Research reactor facility of Curtiss-Wright Corporation of Woodridge, N.J., in Covington Township, Clearfield County, discharging into a tributary of Mosquito Creek, flowing into a branch of the Susquehanna River.

March 26. Metallurgical plant of L & S

Machine Co., Inc., of Latrobe, in Unity Township, Westmoreland County, discharging into Four Mile Run, tributary of Loyalhanna Creek.

March 26. Plant for research, development, and manufacture of nuclear reactor components of the Nuclear Materials and Equipment Corporation, of Apollo, in Apollo Borough, Armstrong County, discharging indirectly into the Kiskiminetas River.

April 26. Metallurgical plant processing naturally radioactive metals and producing fuel elements, of Westinghouse Electric Corporation of Pittsburgh, in Derry Township, Westmoreland County, discharging into the Conemaugh River.

May 26. Research reactor of Pennsylvania State University at State College, Centre County, discharging into Thompson Run, tributary of two creeks.

December 23. Testing reactor of Westinghouse Electric Corporation of Pittsburgh, in Sewickley and Hempfield Townships, Westmoreland County, discharging into a tributary of Sewickley Creek.

State and Local Government Expenditures for Health and Hospitals

MARJORIE GOOCH, Sc.D

FOR THE FIRST TIME since 1942, State-by-State data are available on the expenditures of State and local governments for the major functions of these governments (1). The Bureau of the Census obtained these data on the then 48 States and the District of Columbia as part of the 1957 Census of Governments. Although the Census Bureau annually publishes financial statistics for State governments and for cities of more than 25,000 inhabitants (2), similar data for local governments have been available only as estimated nationwide totals. Four functions—education, highways, public welfare, and health and hospitals—accounted for nearly three-fourths of the total State-local general expenditures in 1957. General expenditures represent the amounts spent for public programs but exclude State-owned and State-operated enterprises and trust fund operations.

Of the total general expenditures by State and local governments of \$40.4 billion, health and hospitals accounted for \$3.2 billion—\$2.6 billion for hospitals and \$0.6 billion for health. New York State spent the largest amount for health and hospitals combined (\$521.5 million) and South Dakota the smallest amount (\$5.6 million). Expenditures for hospitals ranged from \$446.0 million in New York State to \$4.1 million in Vermont. Expenditures for health varied from \$75.5 million in New York to somewhat less than \$1 million in Nevada.

Dr. Gooch is a public health research analyst in the Division of Public Health Methods, Public Health Service.

On a per capita basis, the average expenditure by State and local governments for health and hospitals combined was \$18.80; for hospitals, \$15.56, and for health, \$3.24. Aside from the District of Columbia, the State with the highest per capita expenditure for health and hospitals together (New York) spent \$32.30; the State with the lowest per capita expenditure for this purpose (South Dakota) spent about one-fourth this amount, or \$8.06. By far the larger part of these expenditures for health and hospitals went to hospitals; per capita outlays for hospitals (again omitting the District of Columbia) ranged from \$27.62 in New York to \$6.34 in South Dakota. Per capita expenditures for health varied from \$7.93 in Washington to \$1.34 in Iowa.

According to Census Bureau definitions (2), hospital expenditures are the expenditures of State and local governments for the support of hospital facilities (and institutions for the care and treatment of the handicapped) that are established or operated by these governmental units, for the provision of hospital care in private or other governmental hospitals, and for the support of other public or private hospitals. Included are expenditures for hospital facilities operated in conjunction with State colleges or universities as well as payments by the governmental units of hospital bills for the needy and for other classes of the public.

Health expenditures are the amounts spent by State and local governments for public health services and for vendor payments for medical supplies and services, excluding payments for hospital care. Public health services

include public health administration, research, nursing, immunization, clinics, and other general health activities (other than "hospital" activities). They include expenditures for such programs as health examinations and inspections, maternal and child health, school health activities of health departments (but not of school departments), control of cancer, tuberculosis, and mental illness, and other categorical and environmental health activities.

The expenditures reported here are financed from revenue and borrowing, including as revenue amounts received in the form of grants-in-aid from the Federal Government, patient fees, and rental revenues, as well as taxes.

Table 1 shows the per capita expenditures and the dollar amounts for health and hospital services for each State. The States are listed in the order of per capita personal income. Connecticut is at the top, with a per capita income of \$2,821, and Mississippi is at the bottom with a per capita income of \$958.

The median State had a per capita income of \$1,836. The median per capita expenditure for health and hospitals combined was \$16.04; for hospitals it was \$12.76, and for health, \$2.90. In general, States with high per capita incomes reported above-average State and local outlays for health and hospitals combined and for hospitals. The correlation between per capita income and per capita expenditure for health services is less marked.

Of the total \$3.2 billion spent for health and hospitals, \$1.7 billion represents the expenditures of State governments and \$1.5 billion the expenditures of local governments. The amounts expended by State governments varied from \$236 million in New York to slightly less than \$2 million in Nevada. Local government expenditures for this function ranged from a high of \$285 million in New York to a low of \$311,000 in Delaware (table 2).

Although for the United States as a whole, State governments and local governments were about equally responsible for health and hospital expenditures, in 30 States the expenditures of the State government exceeded those of the local governments. In eight States the expenditures of the State government accounted for 80 percent or more of the health and hospital

outlays. At the other extreme, in three States the expenditures of the State government accounted for less than 30 percent of the total health and hospital expenditures (table 3).

No geographic pattern is evident in the division of health and hospital program responsibilities between State governments and local governments. For example, in California local governments spent 63 cents of each dollar, but in Washington and Oregon, only 39 and 29 cents respectively. In New York about 55 cents of each dollar represents local expenditures, and in New Jersey the figure is 61 cents, but in Connecticut, it is only 15 cents. In Georgia local governments spent 66 percent of the total health and hospital expenditures; in Alabama, 56 percent; in Mississippi, 49 percent; in Arkansas, 40 percent; and in Louisiana, 19 percent (table 3).

A total of \$111 million of Federal aid went to State governments to finance these health and hospital expenditures. State governments granted \$253 million to local governmental units for these functions, and \$60 million of local funds was paid to State governments as reimbursement for services performed by the States for localities.

Federal grants to State governments for health and hospital programs ranged from \$8 million in Texas to \$366,000 in Delaware. State aid to local governments ranged from a high of \$73 million in New York to a low of \$16,000 in Maine and New Hampshire. Local governments in 35 States made payments to their respective State governments for health and hospitals ranging from almost \$12 million in New Jersey to \$1,000 in Texas (table 2).

For the United States as a whole (exclusive of the District of Columbia), Federal funds accounted for 3.5 percent of the total expenditures for health and hospitals. In New York Federal funds represented less than 1 percent, but in Alabama and Arkansas they represented 13.8 percent of the total. In 33 States, the proportion of Federal funds exceeded the average of 3.5 percent, and in 19 States it exceeded twice this average. In general, Federal funds accounted for a larger proportion of program outlays in the agricultural and low-income States than in the industrial, high-

income States (table 3), reflecting the grant allocation formulas used for the Hill-Burton hospital construction program and public health programs.

For most States, the proportion of State aid to local governments does not affect the division of program responsibilities between State and local governments. Over the Nation, State aid to local governments for health and hospitals amounted to \$253 million, or 17 percent of local outlays for this function. In California, where local expenditures are a relatively high proportion of the total, State aid to localities is relatively low (7.5 percent). In contrast, in Wisconsin, where localities also make a high proportion of the health and hospital expenditures, State aid finances 30 percent of these expenditures. In several States where local expenditures are comparatively low (for example, Pennsylvania, Louisiana, and Kansas), State aid finances 20 to 30 cents of each \$1 of local expenditures.

In only three States (Massachusetts, Minnesota, and Washington) does the proportion of State aid exceed twice the national average. In two States (Delaware and Vermont) there is no State aid to local governments, and in 13 other States less than 5 percent of the local expenditures were financed by State aid.

Although the expenditures for health and hospitals according to the final spending unit are about evenly divided between State and local governments, local funds account for less than half (42 percent) of the total financing. The local share of funds ranges from 4 percent in Delaware to 75 percent in Nevada. In only three States in addition to Nevada (Iowa, New Jersey, and Wyoming) is the local share as much as 60 percent of the total. In 34 States, local funds account for less than half the total health and hospital expenditures.

The four governmental functions of education, highways, public welfare, and health and hospitals accounted for 71 percent of the total \$40.4 billion State-local general expenditures. The remaining 29 percent covered all the other functions of the State and local governments, such as police and fire protection, tax enforcement, legislative and judicial expense, sanitation, conservation of natural resources, recreation, correction, housing and community redevelopment, employment security administration, and interest on the general debt.

Education accounted for the largest proportion of State and local expenditures in all but two States; highway expenditures generally ranked second. Expenditures for public welfare and for health and hospitals usually ranked third and fourth. The States varied widely in the proportion of expenditures devoted to each function. Exclusive of the District of Columbia, education expenditures ranged from 45 percent of general expenditures in Utah to 24 percent in Massachusetts; highways varied from 33 percent in Connecticut to 13 percent in New York; public welfare, from 19 percent in Oklahoma to slightly less than 4 percent in Virginia; and health and hospitals, from 11 percent in New York to 3 percent in South Dakota.

Table 4 shows for each State the percentage distribution of the expenditures for the four major functions of State and local governments.

Legal note . . . Health Inspections

Constitutionality of ordinance imposing forfeiture on person refusing entry to health inspector without warrant upheld five to four in first decision by U.S. Supreme Court upon question—State court decisions noted. *Frank v. State of Maryland*, 79 S. Ct. 804 (May 4, 1959).

On February 27, 1958, Sanitarian Gentry, an officer of the bureau of rodent control of the Baltimore City Health Department, acting on a complaint that there were rats in the basement of a neighboring house, went to appellant Frank's private dwelling to make an inspection of the premises. Relying on the authority of section 120 of article 12 of the Baltimore City Code, Gentry did not have a search warrant. That section provides:

"Whenever the Commissioner of Health shall have cause to suspect that a nuisance exists in any house, cellar or enclosure, he may demand entry therein in the daytime, and if the owner or occupier shall refuse or delay to open the same and admit a free examination, he shall forfeit and pay for every such refusal the sum of Twenty Dollars."

Receiving no response to a knock at Frank's door, Gentry inspected the area outside the house and found a pile of straw, trash, and debris, including rodent feces, which he estimated at approximately one-half ton. When approached by Frank to explain his presence, Gentry said that he had evidence of rodent infestation and demanded entry into the house to inspect the basement area. Frank refused to permit entry without a search warrant. The next day Frank was arrested, charged with and found guilty of violating the quoted section of the Baltimore Code, and fined \$20. He appealed to the Maryland Court of Appeals which denied certiorari. (The issue presumably was considered settled by *Givner v. State of Maryland* (see below) in which the State Court had previously upheld the constitutionality of the Baltimore ordinance.)

The case was appealed to the Supreme Court of the United States, the appellant Frank charging that the conviction for resisting an inspection of his house without a warrant had been obtained in violation of the "due process" requirement of the 14th amendment to the Federal Constitution in that it violated his right against unreasonable searches and seizures as guaranteed in the fourth amendment to the Constitution. By a five-to-four decision sustaining the conviction the Supreme Court held the ordinance in question did not violate the due process requirements.

After analysis of the historical background of the 4th and 14th amendments, Justice Frankfurter speaking for the majority concluded that:

"... two protections emerge from the broad constitutional proscription of official invasion. The first of these is the right to be secure from intrusion into personal privacy, the right to shut the door on officials of the State unless their entry is under proper authority of law. The second, and intimately related protection, is self-protection: The right to resist unauthorized entry which has as its design the securing of information to fortify the coercive power of the State against an individual, information which may be used to effect a further deprivation of life or liberty or property."

Evidence of criminal action is placed in this second category and, except for limited situations, seizure of such evidence may not be had without a judicially issued search warrant. Here, however, the Court emphasized, no evidence for criminal prosecution was sought to be seized. The attempted inspection was merely

to determine whether conditions proscribed by the Baltimore health code existed, and if they did the owner or occupier would, under the ordinance, have been directed to correct them—to do what he could have been ordered to do even without an inspection. The Court noted that “appellant’s resistance can only be based, not on admissible self-protection, but on a rarely voiced denial of any official justification for seeking to enter his home. The constitutional ‘liberty’ that is asserted is the absolute right to refuse consent for an inspection designed and pursued solely for the protection of the community’s health, even when the inspection is conducted with due regard for every convenience of time and place.”

Thus, in addition to touching only the periphery of the important interests safeguarded by the 14th amendment’s protection against official intrusion—the right to be secure against unauthorized entry to secure evidence for possible criminal action—the inspection here is hedged with safeguards. Under the Baltimore Code, reasonable grounds for suspicion of the existence of a nuisance must exist, the inspection must be made in the daytime, and though a fine may be imposed for failure to allow an inspector in, officials may not enter forcibly.

The Court traced a long history of Maryland laws empowering inspections without warrants, and pointed to the 1801 ordinance of the City of Baltimore in which such a power of inspection became an instrument in the enforcement of the Baltimore health laws. Many thousands of inspections were made under this and similar authority, the Court noted, and the decision quoted with favor from an earlier opinion by Justice Holmes to stress the significance of this long history.

“The Fourteenth Amendment, itself a historical production, did not destroy history for the States and substitute mechanical compartments of law all exactly alike. If a thing has been practiced for two hundred years by common consent, it will need a strong case for the Fourteenth Amendment to affect it. . . .”

The Court, however, disavowed any intention by its holding to “freeze” due process “within the confines of historical facts or discredited attitudes.” The necessity for the exercise of the challenged power to inspect without a war-

rant was, however, viewed as still supported by the situation. The Court declared:

“There is a total want of important modification in the circumstances or the structure of the society which calls for a disregard for so much history. On the contrary, the problems which give rise to these ordinances have multiplied manifold, as have the difficulties of enforcement. The need to maintain basic, minimal standards of housing, to prevent the spread of disease and of that pervasive breakdown in the fiber of a people which is produced by slums and the absence of the barest essentials of civilized living, has mounted to a major concern of American government . . . Time and experience have forcefully taught that the power to inspect dwelling places, either as a matter of systematic area-by-area search, or as here, to treat a specific problem, is of indispensable importance to the maintenance of community health; a power that would be greatly hobbled by the blanket requirement of the safeguards necessary for a search of evidence of criminal acts.”

With respect to the view that the legal protection of privacy requires a search warrant in order to comply with “due process,” the Court rejected a suggestion that the warrant appellant considered necessary from a constitutional point of view could be satisfied by a blanket authorization “for periodic inspections.” The Court concluded that:

“If a search warrant be constitutionally required, the requirement cannot be flexibly interpreted to dispense with the rigorous constitutional restrictions for its issue. A loose basis for granting a search warrant for the situation before us is to enter by the way of the back door to a recognition of the fact that by reason of its intrinsic elements, its historic sanctions, and its safeguards, the Maryland proceedings requesting permission to make a search without intruding when permission is denied does not offend the protection of the Fourteenth Amendment.”

Concurring Opinion of Justice Whittaker

Justice Whittaker, in a separate opinion, concurred in the opinion of the Court, holding that the inspection involved did not amount

to an unreasonable search within the 4th and 14th amendments. He emphasized his understanding that the Court's opinion adhered to the principle that the prohibition of the 4th amendment against unreasonable searches applied to the States through the due process clause of the 14th amendment.

The Dissenting View

Justice Douglas, speaking for the minority, read the fourth amendment differently and declared: "The Court misreads history when it relates the Fourth Amendment primarily to searches for evidence to be used in criminal prosecutions." The security of one's privacy against arbitrary intrusion by the police protected by the fourth amendment, the dissent argued, does not exclude invasions for purposes of inspecting sanitary conditions. This would certainly be true with respect to those States where the presence of unsanitary conditions gives rise to criminal prosecutions. Even under the Baltimore City Code in question, since in resisting an attempt to make an inspection without a warrant appellant was invoking a constitutional protection, the imposition of any fine, regardless of amount, the dissent stated, is unconstitutional.

The dissent viewed the protection of the fourth amendment against unreasonable searches and seizures as designed to protect not only criminals, but as a reflection of the common-law right of a man to privacy in his home, unrelated to crime or suspicion of crime. They pointed to historical applications of this right in a wider frame of reference than only criminal prosecutions, and argued, further, that the more restricted application of the fourth amendment by the Court's decision had no basis in reason (quoting from, *District of Columbia v. Little*, 178 F. 2d 13, 17, affirmed on other grounds, 339 U.S. 1—see below): "To say that a man suspected of crime has a right to protection against search of his home without a warrant, but that a man not suspected of crime has no such protection, is a fantastic absurdity."

The dissent pointed out that the appellant sought to keep the inspector out only until a warrant was obtained. None was sought. In the view of the dissenters, the case was a poor

one to dispense with a need for a warrant since evidence necessary to obtain one was abundant—the extreme decay and the pile of filth. The dissent went on to say that the test of "probable cause" required by the fourth amendment before a search warrant may be issued may take into account the nature of the search being sought, for example, "considerations of health and safety." This approach, the opinion declared, was not to sanction synthetic search warrants but to recognize that the showing of a probable cause in a health case might have quite different requirements than one required in a graver situation.

State Decisions Noted

Although those cases were not before it, the Supreme Court decision in *Frank* reflects support for recent holdings of the Maryland and Ohio Supreme Courts. In *Givner v. State*, 210 Md. 484, 124 A. 2d 764 (1956), the Maryland Supreme Court, in upholding the constitutionality of the same Baltimore provision under attack in the *Frank* case, held that reasonable searches are not barred by the Federal or Maryland constitutions. An inspection without a warrant for the purpose of protecting the public health and safety, that court held, does not fall within the constitutional proscription against searches for evidence of crime. Under the ordinance in question, the court noted, and as the U.S. Supreme Court reemphasized in *Frank*, that the owner of a dwelling is ordered merely to correct the violations. Prosecution can only then be undertaken for failure to do so. The Maryland court concluded that the case fell within one of the suggested intermediate, constitutional areas in which governing agencies may lawfully provide for general routine inspections at reasonable hours without search warrants.

The Ohio Supreme Court made a similar determination with respect to a Dayton ordinance requiring the owner of a dwelling to grant free access thereto at any reasonable hour to a housing inspector for the purpose of conducting a health inspection in *State v. Price*, 151 N.E. 2d 523 (1958). In holding the ordinance constitutional the court noted that, under the provisions of the ordinance, before an owner could be forced to open his premises a court order would

have to be obtained. Similarly, where contemplated, prosecution for the violation of a final order would have to be based on evidence obtained at a reinspection, or at least at some time subsequent to the original inspection if it had been made without a warrant. Thus, the question of the use of evidence obtained without a warrant was held not before the court, and the issue was merely whether the inspection authorized by the ordinance constituted an unreasonable search.

In *District of Columbia v. Little*, 178 F. 2d 13 (D.C. Cir., 1949), the Circuit Court of Appeals in a two-to-one decision reversed a conviction under a District of Columbia law imposing a fine for a houseowner's "interference" with a health inspection and held that the fourth amendment prohibits such a search without a warrant. On appeal to the Supreme Court of the United States, the *Little* decision was

affirmed, 339 U.S. 1 (1950), but on nonconstitutional grounds, the Court determining that defendant's action in refusing entry did not constitute an "interference" within the meaning of the applicable District of Columbia Act.

NOTE: On June 8, 1959, 79 S. Ct. 978, by a vote of four to four (one Justice abstaining) the Supreme Court of the United States noted probable jurisdiction in *State ex rel Eaton v. Price* (discussed under "State decisions" above). As pointed out in the memorandum by Justice Clark (who objected to this action), this case is apparently "on all fours" with the *Frank* case "except that the penalty provision in Maryland's Act is \$20, while that of Ohio's law is a maximum of \$200, or a jail sentence not exceeding 30 days." The case will probably be set for argument in the 1959-1960 term of the Court.

—SIDNEY EDELMAN, assistant chief, Public Health Division, Office of General Counsel, Department of Health, Education, and Welfare.

Correction

In the paper, "Poliomyelitis in the United States, 1957," *Public Health Reports*, vol. 74, June 1959, p. 536, table 1 should be replaced by the following:

Milk Sanitation Honor Roll for 1957-59

Fifty communities have been added to the Public Health Service milk sanitation "honor roll," and 64 communities on the previous list have been dropped. This revision covers the period from July 1, 1957, to June 30, 1959, and includes a total of 289 cities and 97 counties.

Communities on the honor roll have complied substantially with the various items of sanitation contained in the milk ordinance recommended by the U.S. Public Health Service (PHS Publication No. 229: "Milk Ordinance and Code—1953 Recommendations of the Public Health Service"). The State milk sanitation authorities concerned report this compliance to the Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk sold is pasteurized, and for those in which both raw milk and pasteurized milk are sold.

The recommended milk ordinance, on which the milk sanitation ratings are based, is now in effect through voluntary adoption in 490 counties and 1,424 municipalities. The ordinance also serves as the basis for the regulations of 35 States and Hawaii. In 15 States and Hawaii it is in effect statewide.

The ratings do not represent a complete measure of safety, but they do indicate how closely a community's milk supply conforms with the standards for grade A milk as stated in the recommended ordinance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk sold in a community which also permits the sale of raw milk.

Although semiannual publication

This compilation is from the Milk and Food Program, Division of Engineering Services of the Bureau of State Services, Public Health Service. The previous listing was published in Public Health Reports, March 1959, pp. 277-280. The rating method was described in Public Health Reports 53: 1386 (1938); reprint No. 1970.

of the list is intended to encourage communities operating under the recommended ordinance to attain and maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they are more than 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion on this list.

The rules for inclusion of a community on the honor roll are:

1. All ratings must be determined by the State milk sanitation authority in accordance with the Public Health Service rating method, which is based upon the grade A pasteurized milk and the grade A raw milk requirements of the Public Health Service recommended milk ordinance. (A departure from the method described consists of computing the pasteurized milk rating by weighting the pasteurization plant rating twice that of the raw milk intended for pasteurization.)

2. No community will be included on the list unless both its pasteurized milk and its retail raw milk ratings are 90 percent or more. Communities in which only raw milk is sold will be included if the retail raw milk rating is 90 percent or more.

3. The rating used will be the latest submitted to the Public Health Service, but no rating will be used which is more than 2 years old. (In order to promote continuous rigid enforcement rather than occasional "cleanup campaigns," it is suggested that, when the rating of a community on the list falls below 90 percent, no resurvey be made for at least 6 months. This will result in the removal of the community from the subsequent semiannual list.)

4. No community will be included on the list whose milk supply is not under an established program of official routine inspection and laboratory control provided by itself, the county, a milk-control district, or the State. (In the absence of such an official program, there can be no assurance that only milk from sources rating 90 percent or more will be used continuously.)

5. The Public Health Service will make occasional check surveys of cities for which ratings of 90 percent or more have been reported by the State. (If the check rating is less than 90 percent, but not less than 85, the city will be removed from the 90-percent list after 6 months unless a resurvey submitted by the State during this probationary period shows a rating of 90 percent or more. If the check rating is less than 85 percent, the city will be removed from the list immediately. If the check rating is 90 percent or more, the city will be retained on the list for 2 years from the date of the check survey, unless a subsequent rating during this period warrants its removal.)

Communities awarded milk sanitation ratings of 90 percent or more, July 1957-June 1959

Milk Sanitation Honor Roll for 1957-59

Fifty communities have been added to the Public Health Service milk sanitation "honor roll," and 64 communities on the previous list have been dropped. This revision covers the period from July 1, 1957, to June 30, 1959, and includes a total of 289 cities and 97 counties.

Communities on the honor roll have complied substantially with the various items of sanitation contained in the milk ordinance recommended by the U.S. Public Health Service (PHS Publication No. 229: "Milk Ordinance and Code—1953 Recommendations of the Public Health Service"). The State milk sanitation authorities concerned report this compliance to the Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk sold is pasteurized, and for those in which both raw milk and pasteurized milk are sold.

The recommended milk ordinance, on which the milk sanitation ratings are based, is now in effect through voluntary adoption in 490 counties and 1,424 municipalities. The ordinance also serves as the basis for the regulations of 35 States and Hawaii. In 15 States and Hawaii it is in effect statewide.

The ratings do not represent a complete measure of safety, but they do indicate how closely a community's milk supply conforms with the standards for grade A milk as stated in the recommended ordinance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk sold in a community which also permits the sale of raw milk.

Although semiannual publication

This compilation is from the Milk and Food Program, Division of Engineering Services of the Bureau of State Services, Public Health Service. The previous listing was published in Public Health Reports, March 1959, pp. 277-280. The rating method was described in Public Health Reports 53: 1386 (1938); reprint No. 1970.

of the list is intended to encourage communities operating under the recommended ordinance to attain and maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they are more than 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion on this list.

The rules for inclusion of a community on the honor roll are:

1. All ratings must be determined by the State milk sanitation authority in accordance with the Public Health Service rating method, which is based upon the grade A pasteurized milk and the grade A raw milk requirements of the Public Health Service recommended milk ordinance. (A departure from the method described consists of computing the pasteurized milk rating by weighting the pasteurization plant rating twice that of the raw milk intended for pasteurization.)

2. No community will be included on the list unless both its pasteurized milk and its retail raw milk ratings are 90 percent or more. Communities in which only raw milk is sold will be included if the retail raw milk rating is 90 percent or more.

3. The rating used will be the latest submitted to the Public Health Service, but no rating will be used which is more than 2 years old. (In order to promote continuous rigid enforcement rather than occasional "cleanup campaigns," it is suggested that, when the rating of a community on the list falls below 90 percent, no resurvey be made for at least 6 months. This will result in the removal of the community from the subsequent semiannual list.)

4. No community will be included on the list whose milk supply is not under an established program of official routine inspection and laboratory control provided by itself, the county, a milk-control district, or the State. (In the absence of such an official program, there can be no assurance that only milk from sources rating 90 percent or more will be used continuously.)

5. The Public Health Service will make occasional check surveys of cities for which ratings of 90 percent or more have been reported by the State. (If the check rating is less than 90 percent, but not less than 85, the city will be removed from the 90-percent list after 6 months unless a resurvey submitted by the State during this probationary period shows a rating of 90 percent or more. If the check rating is less than 85 percent, the city will be removed from the list immediately. If the check rating is 90 percent or more, the city will be retained on the list for 2 years from the date of the check survey, unless a subsequent rating during this period warrants its removal.)

Communities awarded milk sanitation ratings of 90 percent or more, July 1957-June 1959—Con.

NOTE: In these communities the pasteurized market milk shows a 90 percent or more compliance with the grade A pasteurized milk requirements, and the raw market milk shows a 90 percent or more compliance with the grade A raw

milk requirements, of the milk ordinance recommended by the United States Public Health Service.

Notice particularly the percentage of the milk pasteurized in the various communities listed. This percentage is an important factor to

consider in estimating the safety of a city's milk supply. All milk should be pasteurized, whether commercially or at home, before it is consumed.

A Philadelphia center gives the city's senior citizens professional aid in coping with the mental hazards of aging.

A Mental Health Program for the Later Years

JACOB TUCKMAN, Ph.D., and ALICE T. DASHIELL

TODAY'S increased proportion of older people in the population has intensified our interest in more complete understanding of the adult. Society recognizes and accepts the facts of the physical changes with age, but has not recognized fully its economic implications and its social and psychological consequences.

Lessened opportunities for gainful employment, the need to live on a reduced income, the decreased size of the household owing to the dispersion of the family now grown up, widowhood, death of contemporaries, gradual or sudden loss of health, the time and energy costs of traveling or carrying on a hobby, all these and many more problems demand adjustment. Some adults can make such adjustments with great flexibility, but many others do not.

Statistics pertaining to admissions to State hospitals and the age distribution of their resident-patient population indicate the difficulty experienced by some older people in making a

satisfactory adjustment to their day-to-day problems. For the year 1955 in the United States, 26 percent of all first admissions to State hospitals were people 65 years of age and over, and 28 percent of the resident-patient population were in this age group (1).

Community Services

Most older people have the potential for meeting many of their special needs and problems but they may require help at some crucial point. Unfortunately, community services, especially to the nonindigent aged, have not kept pace with the need. Mathiasen has pointed out that in the distribution of funds by community chests and united funds in 255 cities, the amount allocated to care of the aged is at the bottom of the list (2).

Most services for noninstitutionalized older people have taken the form of "golden age clubs" where opportunities for recreation and social contacts are given. Less frequently, activity centers include facilities for arts and crafts, adult education, and cultural interests, in addition to opportunities for recreation and socialization. While golden age clubs and activity centers for older people have been useful as focal points in promoting the welfare of older persons, they have certain shortcomings. They focus only on some needs of the person rather than his total needs. Frequently leaders are untrained in dealing with the pressing prob-

Dr. Tuckman is chief of the section on psychological services, education, and standards, division of mental health, public health services, Philadelphia Department of Public Health, and consultant for Philadelphia's Adult Health and Recreation Center. Miss Dashiell, an associate in the division of mental health, is director of the center. This paper was presented at the American Orthopsychiatric Association's 36th annual meeting at San Francisco, Calif., last spring.

EXPERIMENTAL LYMPHOCYTIC CHORIOMENINGITIS OF MONKEYS AND MICE PRODUCED BY A VIRUS ENCOUNTERED IN STUDIES OF THE 1933 ST. LOUIS ENCEPHALITIS EPIDEMIC

By CHARLES ARMSTRONG, *Surgeon, United States Public Health Service*, with Pathology by R. D. LILLIE, *Surgeon, United States Public Health Service*

In the transmission from monkey to monkey of infectious materials derived from a fatal case of the 1933 St. Louis epidemic of encephalitis, a virus has been encountered apparently quite distinct from the strains previously isolated in monkeys by Muckenfuss, Armstrong, and McCordock, and subsequently in white mice by Webster and Fite. This virus, which differs from any virus with which the author is familiar, will be designated in this paper, from the pathological picture produced by intracerebral inoculation of monkeys and mice, as the virus of experimental lymphocytic choriomeningitis.

ORIGIN OF THE VIRUS

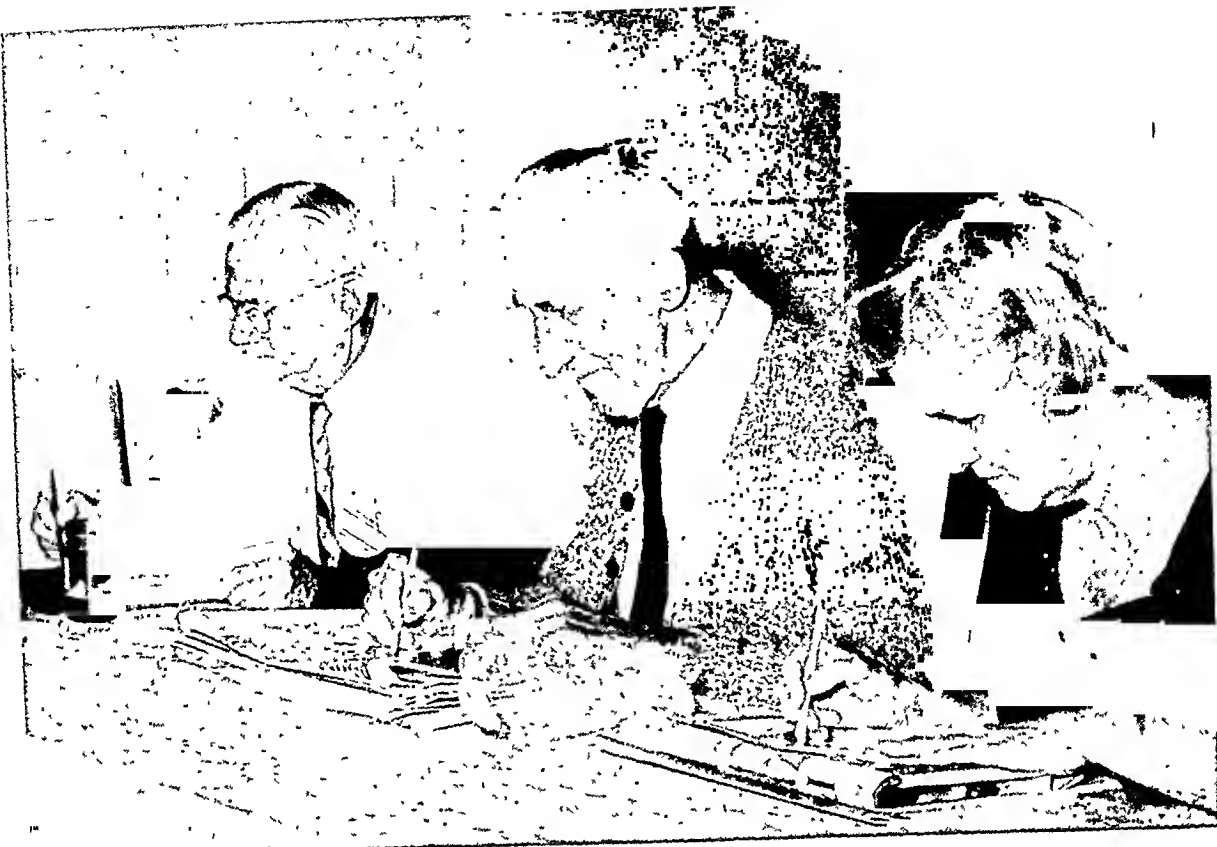

The virus was encountered during monkey-to-monkey transfer of infection from a patient C.G., who died during the 1933 St. Louis epidemic of what was apparently encephalitis of the type prevailing there, as judged by the symptoms and central nervous system pathology.

HISTORY OF CASE

Case C.G., colored housewife, 42 years of age, resident of St. Louis County, had been in poor health for the preceding 12 years; suffered with chronic constipation and had had an abdominal operation; was said to suffer from diabetes. She had been in usual health during 3 weeks prior to present illness, which began on August 13, 1933, with general malaise—"just sick all over."

AUGUST 31, 1934, pp. 1019-1027

Dr. Charles Armstrong describes for the first time a neurotrophic virus, quite distinct from the 1933 strains of St. Louis encephalitis, but encountered during experimental transmission of those strains. Dr. R. D. Lillie describes the pathology produced by the virus in monkeys and mice.

Handicraft activities in Philadelphia's mental health program for the later years

It is the policy of the center to accept into membership only ambulatory persons able to care for their own physical needs who are sufficiently well oriented mentally to make constructive use of the program. Although publicity has indicated that the program is available to persons 60 years of age and older to prevent confusion about the purpose of the center, admission is open to any adult who can benefit from the program. A number of people in their fifties with problems of aging have been accepted. There are no eligibility requirements with respect to sex, race, ethnic affiliation, or residence within the city. Applicants may be referred from any source or may be self-referred. No charge is made for any service.

Before admission to the center, the applicant goes through an intake process which is limited usually to one interview but may include medical or psychiatric consultation. At the interview, the applicant discusses his problems as he sees them and his views on the center as a

possible source of help. The social worker explains to the applicant the various phases of the center's program and together they select the pertinent services. Many applicants request immediate medical consultation and referral for treatment. Other applicants have expressed unhappiness, anxieties, nervousness, or symptoms which they describe as "break-down." For these men and women, psychiatric consultation is offered and accepted readily. In other cases the important problem is finding full- or part-time employment. Usually, the applicant requests an opportunity to participate in the recreational and social activities.

The only requests for service that have been rejected are from agencies seeking psychiatric diagnostic services for clients who would not be able to participate in the center's program. In such cases, it has been explained that the center operates as a unit, combining recreation with medical, psychiatric, psychological, and case-work services, none of which functions sepa-

lems confronting the older person. And standards of operation are often below normal in terms of physical facilities, program, and staff.

The Philadelphia Plan

To give full recognition to the importance of the whole person in meeting the needs of older people, the Philadelphia Department of Public Health, through its division of mental health, established the Adult Health and Recreation Center as a demonstrational mental health facility designed to serve the following purposes:

1. Provide evaluation, counseling, and supportive services to help older adults understand their own aging as a natural process, to develop satisfying and continuing interests, to promote constructive individual and group relationships, to promote physical and emotional well-being, and to help them understand and adjust to the economic, physiological, and psychological problems associated with aging.

2. Provide training for individuals who plan to work with older people or who are presently engaged in such work.

3. Conduct research and make the center available to educational institutions as a research center to develop a better understanding of the aging process and of the problems and treatment of "normal" older people.

The center, officially opened in the middle of November 1958, is well located. According to the 1950 census of population, more than 6,000 persons 65 years of age and older live within a mile of the center. The median income for a family of five within this area is \$3,100 a year.

While the center offers the range of activities usually available in golden age clubs or other centers for older people, it possesses an unprecedented factor of clinical orientation within the various related professional disciplines of psychiatry, psychology, social work, public health nursing, and general medicine. The center is designed for "normal" older people and is not a treatment center for the physically or mentally ill. The center is open from 8:45 a.m. to 5:15 p.m. Monday through Friday although at present the group program is conducted from 9:30 a.m. to 12:30 p.m. daily. Afternoon activities will be scheduled when funds become available.

A series of afternoon meetings open to the public has been started. The first dealt with the medical problems of men and women past middle age and accident prevention in the later years. Future meetings will be devoted not only to health but also to income maintenance, housing, use of leisure time, mental health, and other aspects of aging. With the help of a consultant in nutrition, consideration is being given to a lunch program.

Because of the experimental nature of the center, emphasis is placed on an intensive service to a limited number of people rather than an attempt to meet the needs of older people on a mass basis. On any one day, the number of people to be served may be limited to about 50, but the decision regarding the optimum size of the group will be made after more experience with the program. However, total enrollment may be as high as 200 to 250 since all participants would not use the center's facilities every day.

The center is operated under the joint sponsorship of Philadelphia's Department of Public Health and Department of Recreation and the Pennsylvania Department of Public Welfare. A group of professional and lay leaders serve as an advisory committee.

Staffing and Policies

A State grant of \$15,000 for the current fiscal year makes it possible to hire a social worker as director of the center, a secretary on a full-time basis, three recreation leaders, and an occupational therapist 15 hours a week, and to meet certain overhead expenses. With the exception of the occupational therapist, the personnel mentioned have been hired. The department of public health has contributed to the program the services of a physician, two psychiatrists, two psychologists, a psychiatric caseworker, and a mental health consultant in public health nursing. With the exception of the general medical practitioner who is at the center 9 hours a week, each of these staff members devotes 3 hours a week to the program. Certain supplies and equipment are also provided by the health department. The department of recreation has made space available for housing the program in its most modern plant, built at a cost of \$1½ million.

gists, the public health nurse, and caseworkers are recorded in detail and filed in the case folder. Separate weekly individual records are kept by the recreation leaders, giving data on attendance, participation in activities, and some statement about the adjustment of the individual in the group. Most of these records are written in longhand and entries are kept brief or checked under appropriate captions.

Two referral resources are of special interest. The first is the Comprehensive Medicine Clinic, the general medical clinic of Temple University Medical Center. This clinic is staffed by senior medical students, with internists, psychiatrists, and social workers as consulting supervisors and teachers. For the most part, the internists and psychiatrists work as teams and the skills in social work are added wherever indicated. This permits measurements of biological, psychiatric, and sociological parameters in patients as indicated and the application of appropriate and multidisciplined therapies. The Comprehensive Medicine Clinic not only correlates the work of a number of biologically oriented subspecialists but also attempts to understand the patient in his social, psychological, and physiological milieus. The clinic has agreed to accept all individuals referred by the center for inpatient or outpatient care. Fees are on a sliding scale based on the ability of the person to pay. In return, the center has agreed to accept referrals from the clinic of those patients which the clinic's staff feels will benefit from the center program.

The second resource is the Pennsylvania State Employment Service, bureau of employment security, which has agreed to accept referrals of individuals seeking full- or part-time employment. These persons are seen by the older worker specialists in the employment service on an appointment basis for counseling and job placement.

Analyses of Participants

In just under 4 months of operation, 135 applications have been received. Of this number 85 are active participating members, 30 are pending, awaiting intake interviews scheduled but not yet completed, 15 did not keep their ap-

pointment for an intake interview, and 5 were not accepted because they required other services not available in the center or because they were too sick to participate in the program.

In the active membership of 85, 39 are men and 46 women. Included are nine married couples. Only three in the active membership are nonwhite. The members range in age from 52 to 86, with the median at 67.7 years. The distribution by religious affiliation shows 40 Protestants, 24 Catholics, and 21 Jews. Forty-one are married, 31 are widowed, 8 are single and 5 are separated. Most have completed 6, 7, or 8 years of schooling; only four have a high school education and one has had some college training. One is illiterate.

Employment histories show that most have had *stable employment in skilled or semiskilled occupations* while a few were self-employed. Analysis of living arrangements reveals that 42 own their own homes, 20 rent apartments or houses, 16 are living with relatives, and 7 live in roominghouses. Income of the participants is generally limited to OASI benefits but in some cases this is supplemented by small pensions; only five receive public assistance.

Participants reside in all parts of Philadelphia, the majority from outside the immediate area, but recently men and women living in the neighborhood have begun to show an interest in the center's services. Predominantly participants were self-referred as a result of newspaper publicity or were referred by friends. Up to the present time relatively few have been referred by voluntary health and welfare agencies.

Of the 85 active members, 28 have availed themselves of medical consultations, 8 of psychiatric consultation, and 11 of employment counseling. Of the last group, five were referred to the Pennsylvania State Employment Service for job placement for full- or part-time employment. Thirteen have been referred to medical facilities: 10 to the Temple University Comprehensive Medicine Clinic, 1 to another hospital, and 2 to chest X-ray units.

Daily attendance in the group program has been spotty. On some days as many as 30 people attend; on others, just a handful. A variety of factors, some within the center's control and

rately, even though the applicant may begin by using one service in order to find the solution to his particular problem.

When an applicant wishes to avail himself of all the services offered by the center, the caseworker assists him in analyzing his problems and selecting the most urgent aspect or the one for which he is most ready to accept help.

An example illustrates this process. A 65-year-old widow, childless and living alone in her own small home, received only \$57 a month in old-age and survivors insurance benefits and was unwilling to apply for supplemental public assistance because of the attendant State requirement of placing a lien on her property. A history of diabetes and a gangrenous condition of both legs made her usual employment as a laundry worker impractical. Her small income was insufficient to cover the cost of medical care, medication, and adequate diet.

In desperation and nearly at the point of coma, she called the center saying that she had heard of its new hospital services. After the center's functions were explained to her, an appointment for an interview was made. She was aided in keeping it and in returning again for medical consultation. Throughout these contacts, although she insisted she really wanted help in finding employment, she was actually asking for help on the basis of what she thought would be acceptable. Finally she accepted medical advice and referral to a hospital for treatment as a first step. The diabetic condition was so acute that immediate hospitalization was arranged.

From the hospital, the woman, with unmistakable relief in her voice, telephoned the center to express appreciation of its services and was assured that after discharge the center would help her to satisfy her needs for social contacts and part-time employment.

Integration of Skills

The importance of integrating the several professional skills in this new program cannot be too greatly emphasized. Periodic staff meetings, case conferences, and sharing of records to which each of the professional disciplines contributes are helping to define the role of each of the disciplines in the program.

It is evident already that a caseworker is essential to the intake process by enabling the applicant to obtain maximum value from the available services in relationship to his physical and psychological status. The psychiatrist evaluates the applicant's capacity to use the program, and advises the center's staff in helping the individual adjust to the group program. The psychologist may participate in diagnosis and evaluation, through the use of psychological procedures, and in vocational exploration with applicants seeking employment. The general medical practitioner helps these older persons to understand their medical problems, recommends treatment where indicated, and advises the staff on appropriate center activities for individuals with health problems. The public health nurse consultant is helpful in giving advice on self-care required to carry out medical recommendations. The physician and psychiatrists will supervise the occupational therapist when such a person is hired.

The representatives of each discipline act as consultants to the director, contributing to a better understanding of the individual and his needs and, where indicated, making recommendations for referral to appropriate resources in the community. In referrals to medical facilities, existing doctor-patient relationships are not disturbed. As the program develops, it is planned that all the professional disciplines will be utilized in both group discussion and group psychotherapy. The director is responsible for administration and coordination of the program.

The system devised for recordkeeping provides essential information about the older person but at the same time keeps paperwork to a minimum. A registration form, a 5-inch by 8-inch card, is used to record significant information about the individual, including age, sex, race, religion, ethnic background, economic status, employment and health history, and the reason he gives for requesting admission to the program. Simple notes about important factors in his situation and his response to the initial casework interview are written by the worker on the reverse side of the card. For individuals who avail themselves of other services, a case folder is set up. Interviews by psychiatrists, physicians, psycholo-

Stingray Injuries

FINDLAY E. RUSSELL, M.D.

INJURIES inflicted by stingrays are common in several areas of the coastal waters of North America (1-4). Approximately 750 people a year along our coasts are stung by these elasmobranchs. The largest number of stings are reported from southern California, the Gulf of California, the Gulf of Mexico, and the south Atlantic coast (5).

Of 1,097 stingray injuries reported over a 5-year period in the United States (5, 6), 232 were seen by a physician at some time during the course of the recovery of the victim. Sixty-two patients were hospitalized; the majority of these required surgical closure of their wounds or treatment for secondary infection, or both. At least 10 of the 62 victims were hospitalized for treatment for overexuberant first aid care. Only eight patients were hospitalized for the treatment of the systemic effects produced by the venom. There were two fatalities.

Considerable care should be exercised when wading in shallow waters known to be inhabited by stingrays. Stingray injuries usually occur when the unwary victim treads upon the fish while wading in the ocean surf or mud flats of a bay, slough, or river. The fish often buries itself in the sandy or muddy bottom and may remain motionless until stepped upon. The pressure of the foot on the dorsum of the fish provokes him to thrust his tail upward and forward, driving his sting into the foot or leg of the victim. As the sting enters the flesh,

the integumentary sheath surrounding the spine is ruptured and the venom escapes into the victim's tissues. In withdrawing the spine, the integumentary sheath may be torn free and remain in the wound.

Unlike the injuries inflicted by many venomous animals, wounds produced by the stingray may be large and severely lacerated, requiring extensive debridement and surgical closure. A sting no wider than 5 mm. may produce a wound 3.5 cm. long (6), and larger stings may produce wounds 7 inches long (7). Occasionally, the sting itself may be broken off in the wound.

The sting, or caudal spine, is a bilaterally serrated dentinal structure located on the dorsal surface of the animal's tail. The sharp serrations are curved cephalically and as such are responsible for the lacerating effects as the sting is withdrawn from the victim's flesh. The location, size, and number of stings vary with the species, habitat, and age of the fish. The round stingray, now designated as *Urolophus halleri*, which is implicated in the majority of injuries along the southern California coast, has one or more stings of 1.6 to 5.9 cm. long (8). The giant stingray of Australia, *Bathytoshia*, may possess a caudal spine of 42.0 cm. long (9).

The greatest portion of venom is contained within the two ventrolateral grooves of the sting. In the untraumatized state, the sting is incased in an integumentary sheath. The anatomic relationships of the sheath and sting have been described elsewhere (10-12).

Chemical and Zootoxicological Properties

The toxic fractions of the venom are soluble proteins of average molecular weight. They

Dr. Russell is director of the laboratory of neurological research of the College of Medical Evangelists and Los Angeles County Hospital. Basic data in the report were obtained from studies supported by the Office of Naval Research, Dazian Foundation for Medical Research, and the Public Health Service.

others not, appear to account for this. These factors include long travel distance to the center, carfare expense, inclement weather, seasonal illness, morning schedule, location of the center in an area where people are disinclined to use public services, shortage of equipment and supplies, lack of a lunch program, and certain limitations of the building which, though modern and spacious, needs furnishings to give greater warmth and comfort. However, there is every indication that daily attendance will increase as these problems are resolved.

Planned Research

Implicit in this pilot project is the hypothesis that meeting some of an individual's basic needs will result in improved physical and mental health, or at least the prevention of deterioration. Experience and observation already evidence some improvement in the adjustment of those participating in the program, but these subjective judgments need to be supported by more objective evidence.

A study is being planned to test the effectiveness of the program in facilitating the individual's adjustment; this will be undertaken as soon as the program stabilizes. The basic research design will consider three factors: (a) an appraisal of the individual's background, needs, capacities, attitudes, skills, and physical and mental status before entering the program;

(b) an analysis of his participation in the program, stressing the manner in which he performs and relates to others and the reactions of staff and other participants to him; and (c) an analysis and evaluation of the changes that have taken place in his behavior, health, and adjustment after a period of time in the program, such as 6 months or 1 year. Such a study may indicate whether the improvement in the older person comes from the use of former adjustive behavior patterns or by the development of new ones.

It is important to determine whether the improvement is real or superficial and to what extent it is due to relief from loneliness, to an active and regular regimen, or to other factors. It is also important to know what factors motivate individuals to take part in one activity rather than another, what needs are being met by a particular activity or by the program as a whole, how effective the program is in meeting needs, and how the program can be improved.

PHS Grants for Public Health Schools

The Nation's 11 schools of public health were awarded training grants totaling \$450,000 in the last half of fiscal year 1959 to help overcome a national deficit in trained health personnel. A \$1 million grant fund for the same purpose has been awarded for fiscal year 1960. Legislation authorizing such aid by the Public Health Service was passed in 1958, but no funds were available until a supplemental appropriation was voted in May 1959.

The funds will help the schools extend and improve specialty training in public health for physicians, nurses, engineers, and other personnel employed in Federal, State, and local public health agencies in the United States and in foreign health agencies.

An Early Case History

An early stingray victim was Captain John Smith. Walter Russell, "Gentleman, doctor of physicke," who accompanied Smith as he explored Chesapeake Bay in June 1608, described the encounter in chapter 5, "The Accidents that hapned in the Discovery of the Bay of Chisapeack" of *The Third Booke of The Proceedings and Accidents of the English Colony in Virginia*.

. . . Having finished this discovery (though our victuall was neere spent) he intended to see his imprisonment-acquaintances upon the river of *Rapahanock*, by many called *Toppahanock*, but our bote by reason of the ebbe, chancing to grownd upon a many shoules lying in the entrances, we spyed many fishes lurking in the reedes: our Captaine sporting himselfe by nayling them to the grownd with his sword, set us all a fishing in that manner: thus we tooke more in owne houre then we could eate in a day.

But it chanced our Captaine taking a fish from his sword (not knowing her condition) being much of the fashion of a Thornback. but a long tayle like a ryding rodde, whereon the middest is a most poysoned sting, of two or three inches long, bearded like a saw on each side, which she strucke into the wrest of his arme neere an inch and a halfe: no bloud nor wound was seene, but a little blew spot, but the torment was instantly so extreme, that in foure houres had so swollen his hand, arme and shoulder, we all with much sorrow concluded his funerall, and prepared his grave in an Island by, as himselfe directed: yet it pleased God by a precious oyle Doctor Russell at the first applyed to it when he sounded it with probe, (ere night) his tormenting paine was so well asswaged that he eate of the fish to his supper, which gave no lesse joy and content to us then ease to himselfe. For which we called the island *Stingray Isle* after the name of the fish. . . .

ized cramps, inguinal or axillary pain, and respiratory distress are less frequently reported. Arrhythmias, paresthesias, and convulsions may occur. True paralysis is extremely rare, if it occurs at all. The "paralyses" seen by the author following severe stings were contractures, probably initiated as flexion reflexes stimulated by the intense pain. These contractures were relieved with meperidine hydrochloride.

Treatment

The standard procedure for treatment of stingray injuries is well established (5). As the chief complaint is immediate, intense, localized pain, the treatment will be most successful if the victim initiates it. Injuries to an extremity should be irrigated with the salt water at hand, since much of the venom can be washed from the wound by this step. An attempt should be made to remove the integumentary sheath if it can be seen in the wound. If a properly qualified person is available, he

may apply a constriction band directly above the wound site. The extremity should then be submerged in hot water at as high a temperature as the patient can tolerate without injury for 30 to 90 minutes. The addition of sodium chloride or magnesium sulfate to the hot water is optional.

In many areas of the United States the life-guard services provide the first aid care just described, and the victim usually arrives at the hospital emergency room or physician's office in little acute pain and with few, if any, other complaints. The wound should then be further examined for evidence of the integumentary sheath, debrided, sutured if necessary, and the appropriate antitetanus agents administered. While infections of these wounds are rare in properly treated cases, some physicians routinely give antibiotics. Elevation of the injured extremity is advised.

Irrigation is contraindicated if the sting has entered the abdominal or thoracic cavity, and the patient should be hospitalized. In such cases, the patient should be explored surgically

are extremely labile and rapidly inactivated by heating. Ten amino acids have been identified in the venom. The total nitrogen, carbohydrate, and protein for 100 mg. of the venom has been calculated as 3.1 mg., 3.3 mg., and 24.9 mg. respectively. The intravenous LD_{50} of the lyophilized venom is estimated at 28.0 mg./kg. of body weight (13).

In addition to the local effects (12), the venom produces changes in the cardiovascular, respiratory, nervous, and urinary systems (5, 14, 15). Low concentrations of the toxin give rise to simple, transient peripheral vasodilatation or vasoconstriction. The most consistent change in the electrocardiographic pattern of cats when small amounts of the venom are injected is bradycardia with an increase in the PR interval, giving a first degree atrioventricular block with but slight change in the blood pressure. Reversal of the small dose effect occurs within 30 seconds following the end of the injection (14, 15).

Larger amounts produce constriction of the arteries and veins as well as the arterioles, and second or third degree atrioventricular block. The second degree block is usually followed by sinus arrest. In addition to the PR interval change, ST, T wave changes indicative of ischemia and, in some animals, true muscle injury are seen (15, 16). Concomitant with these changes is a fall in systemic arterial pressure. It is apparent that the venom affects the normal pacemaker of the heart. Most of the cardiovascular changes revert to normal within 24 hours (5).

Lethal amounts of the venom cause marked vasoconstriction and cardiac standstill of varying durations. All degrees of atrioventricular block as well as defects in intraventricular conduction occur, and if death is not immediate, the rhythm of the normal pacemaker is replaced by one elaborated outside the sino-atrial node. The blood pressure falls rapidly, and the animal dies in complete cardiovascular collapse (5, 14, 15). Concomitant with these changes are alterations in the respiratory and central nervous systems (5, 13). The venom has no effect on neuromuscular conduction (17). Postmortem examination of animals which have survived for 4 days following a lethal dose of

the venom show few gross changes. However pulmonary edema, engorgement of the liver sinusoids, and vascular congestion with tubular epithelial necrosis in the loop of Henle are seen (13).

Diagnosis

Persons stung by stingrays report having received a sharp, painful stab, usually in the foot or leg, while swimming or wading in an area where these animals are present. The pain is usually described as intense or excruciating; it increases in severity during the first 90 minutes following the stinging if treatment is not instituted. The pain is out of proportion to that which might be produced by a nonvenomous fish or by stepping upon a broken bottle or bivalve. "Stingings" by broken bottles are a common occurrence along certain of our coasts, according to the lifeguard services.

Examination reveals either a puncture or a lacerating wound, usually the latter, jagged, bleeding freely, and often contaminated with parts of the stingray's integumentary sheath. The edges of the wound may be discolored, though the discoloration is not usually marked immediately following the injury. However, within 2 hours the discoloration may extend several centimeters from the wound. Subsequent necrosis of this area is not uncommon in untreated cases.

Edema is a constant finding following stingings by these animals. The edema is not as severe as one sees following a rattlesnake bite, but it may persist for several weeks in the untreated case. Syncope, weakness, nausea, nervousness, and sweating are common complaints. Vomiting, diarrhea, tremors, general

films

The Innocent Party

16-mm. film, color, sound, 17 minutes, 1959.

Audience: Students, parents, educators, civic groups, health workers, and the general public.

This film, depicting the problems of teenagers with venereal diseases, documents simply, forthrightly, and in good taste the nature, recognition, cure, and control of syphilis.

Suitable for mixed audiences, it was shown before release to groups of parents, teachers, educators, Catholic and Protestant clergy, public health officials, and teenagers.

The film was produced by the Kansas State Board of Health in cooperation with the Public Health Service. It may be borrowed from the film library of the Communicable

Disease Center, Atlanta, Ga., by high schools, colleges, youth organizations, and civic groups, as well as health departments, and will be offered for sale by an independent contractor.

Information concerning loan or purchase may be obtained from Dr. William J. Brown, Chief, Venereal Disease Branch, Communicable Disease Center, Public Health Service, 50 Seventh Street NE., Atlanta 23, Ga.

George Washington's River

16-mm. film, color, sound, original music, 28 minutes, cleared for television, 1959.

Audience: Sanitarians, persons interested in conserving natural resources, and the general public.

From a depiction of George Washington's time when he built his home at Mount Vernon "on the finest river in the world," this new water pollution film takes the audience to

present-day scenes of the polluted Potomac. The ugliness of the pollution emanating from the metropolitan area is contrasted with the fresh, clear headwaters of the Potomac. Scenes include national shrines, cherry blossom time at the Tidal Basin, and a long-forgotten bathing beach in Washington.

The film shows how cities and industries can manage their wastes and restore the streams for fishing, boating, swimming, and domestic and industrial requirements.

Film libraries or agencies considering the purchase of a print can obtain a preview copy from the Division of Water Pollution Control, Public Health Service, Washington 25, D.C. Distribution for public showings will be made from film service libraries only.

Prints can be purchased, at \$95.42 each postpaid, from the Motion Picture Service, Office of Information, U.S. Department of Agriculture, Washington 25, D.C.

for the presence of the ray's integumentary sheath (5). Exploration is indicated if the sting has pierced the peritoneum or pleura. Such exploration may require considerable time, since the sheath may be torn into several small pieces. The venom is rapidly absorbed in the peritoneal cavity, and should the offending ray be a large one, the prognosis is poor in the presence of an unremoved sheath. It is also possible for the toxin to be expressed from the venom apparatus without the sheath being left in the wound.

In severe stings, which provoke systemic symptoms, the victim should also be hospitalized. The primary shock often seen immediately following these injuries usually responds to simple supportive measures. If secondary shock develops as a result of the direct effects of the venom, the physician must direct his efforts toward maintaining cardiovascular and respiratory tone. Oxygen should always be given. Meperidine hydrochloride has been found to be effective in controlling the pain (5, 6). Experiments with mice have shown that the drug does not alter the LD₅₀ of the venom (5).

Summary

Injuries inflicted by stingrays are common in several areas of the coastal waters of North America. Approximately 750 people a year along our coasts are stung by these elasmobranchs. About 20 percent of those injured are seen by a physician some time during the course of their recovery; 6 percent are hospitalized.

In the untraumatized state, the sting is encased in an integumentary sheath. The greatest portion of the venom is contained within the ventrolateral grooves of the sting.

The toxic fractions of the venom are soluble proteins of average molecular weight which are extremely labile and rapidly inactivated by heating. While the venom produces changes in the respiratory and central nervous systems, its principal action is on the cardiovascular system.

The chief complaint following a sting by one of these animals is severe pain. Syncope, weakness, nausea, nervousness, and sweating

are common complaints. Vomiting, diarrhea, tremors, generalized cramps, inguinal or axillary pain, and respiratory distress are less frequently reported. Arrhythmias, parasthesias, and convulsions may occur.

Treatment is aimed toward alleviating the pain, preventing complications that may be evoked by the venom, and preventing secondary infections. The following therapy is suggested. Irrigate the wound thoroughly, removing the animal's integumentary sheath if present. Apply a constriction band directly above the wound site until hot water can be prepared. Soak affected part in hot water for 30 to 90 minutes. Debride and close wound as necessary. Administer appropriate antitetanus agent and antibiotic. Keep affected part elevated.

Hospital Use in Hagerstown

MARGARET D. WEST and RUTH M. RAUP

DURING RECENT DECADES, many changes have taken place in patterns of medical care. Besides new methods of preventing and treating illness and disability, new forms of organizing and financing medical and hospital care have emerged making possible more efficient provision of services and a lighter burden of medical care costs for some individuals. Changes in the character of the population, such as the increase in the proportion of older persons, have altered the relative importance of certain diseases and injuries. What has been the effect of these and other changed conditions on the utilization of hospital care?

Since the early 1920's the Public Health Service has conducted a series of studies on the health status in Hagerstown, Md., a small city selected as representative in demographic characteristics of communities in the eastern United States. Among these studies have been household morbidity surveys, the first conducted in the period 1921-24 (1) and the latest during 1955-57 (2).

The 1955-57 survey showed that most of the hospital care of the surveyed population was provided in the Washington County Hospital in Hagerstown. The same hospital provided most of the hospital care for residents of the area in 1921-24. Because this hospital maintains an excellent index of patient discharges covering both the earlier and the later survey periods, a valuable opportunity was presented for comparison of the city's rates and patterns of hospitalization over an interval of about 35 years.

Methods

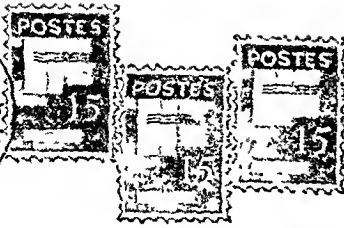

Information on hospitalization in the 1921-24 and 1955-57 surveys was collected by check-

ing the name of each individual in the survey against the discharge records of the Washington County Hospital for the period of his inclusion in the survey. The population surveyed in 1921-24 numbered 9,946 individuals, representing about one-third of the city's total population at that time (28,064 in the 1920 census). The group in 1955-57, about one-twentieth of the total population of 36,260 in the 1950 census, was made up of 1,868 individuals, including 22 who died during the survey period.

As a basis for computing hospitalization rates, the number of individuals surveyed was multiplied by the period of coverage of the individuals to give the total person-years of experience on which information was obtained. In the 1921-24 survey, the total number of person-years of experience reported on was 18,790. Person-years in the more recent survey totaled 2,935, with about half of the individuals covered for 1 year and most of the rest for 2 years.

Both the 1921-24 and 1955-57 survey populations were generally representative of the total Hagerstown population in sex and age distribution, as reported in the 1920 and 1950 censuses. The earlier sample was picked by interviewing all households in sections of the city which represented different economic classes. The 1955-57 sample was drawn at random from households listed in the Hagerstown city directory. Only white households were included in the 1921-24 survey, whereas about 3 percent of the persons surveyed in 1955-57 were Negroes.

Mrs. West is chief of the Health Service Requirements Branch, and Miss Raup, public health research analyst, in the Division of Public Health Methods, Public Health Service.

Medical Center

A national medical center for Korea opened October 2, 1958, in Seoul. The largest modern medical facility in the Far East, the center has 465 beds and was financed with \$2.4 million from UNKRA funds and \$2 million contributed by Norway, Sweden, and Denmark. For its first 5 years of operation the center will have approximately 80 Scandinavian staff members, supported by an annual \$1.5 million contribution from the three countries. The entire facility will be turned over to Korea in 1963.

—ALFRED S. LAZARUS, *chief, Health and Sanitation Division, U.S. Operations Mission, Korea.*

Ojos de Agua

The Ministries of Agriculture, Education, and Health joined forces in a new rural development at Ojos de Agua, a small community in southeastern El Salvador. An earth-cement brick-making machine, used here for the first time, manufactures bricks for a new school, houses, and water supply units. The water units consist of laundries, showers, drinking fountains, watering troughs for animals, and food-washing vats. The community is building approved latrines for each of 420 houses.

—LAMAR A. BYERS and W. C. JAMES, *chief and acting chief, Health and Sanitation Division, U.S. Operations Mission, El Salvador.*

The Well Diggers

Twelve thousand new or rehabilitated wells will be put into operation in East Pakistan this year. The wells will provide a safe source of water. Villagers customarily use open tanks for bathing and laundering as well as for drinking water.

The government of East Pakistan has contracted with 220 small contractors, each with 2 or 3 crews of 4-man gangs, to dig new tube wells or put clogged wells back into service. Most of the wells are less than 200 feet deep. In the Dacca area, 2,294 out of the scheduled 3,370 wells were finished in 30 days.

The village water supply project required nearly 350 miles of 1½-inch galvanized iron pipe, 10,000 hand pumps, 1,000 deep-well hand pumps, and quantities of pipe fittings, strainers, well points, spare parts for the clogged wells, and hand tools.

—ANTHONY DONOVAN, M.D., *chief public health adviser physician, U.S. Operations Mission, Pakistan.*

Tuberculosis in Israel

The number of tuberculosis cases in Israel has dropped so that 750 beds are sufficient for hospitalized tuberculous patients. Other tuberculosis facilities have been converted into general wards, homes for the aged, and mental hospitals.

Ten years ago, when 1,000 immigrants were arriving daily, 12 out of 1,000 had signs of the disease.

Through efforts of the Ministry of Health, trade unions' sick funds, and philanthropic organizations, the number of beds for tuberculosis patients increased from 348 in 1948 to 2,200 by 1953.

Malben, a philanthropic organization, took on the task of rehabilitating discharged patients, totaling 7,000 in 1958 alone.

Malaria in Southeast Asia

To coordinate malaria eradication, 40 officers and technicians from Laos and Thailand met at a border conference at Nongkhai, Thailand, February 2-6, 1959. In 1959 eradication efforts will serve 14 million Thai and 700,000 Lao, an increase of 2 million persons in Thailand and 300,00 in Laos.

In large areas of Thailand the malaria eradication program is almost complete, and less than half of the operational areas require spraying this year. Laos will continue spraying in all operational areas and start surveillance activities in areas of 175,000 population.

—MELVIN E. GRIFFITH, *acting chief, public health division, U.S. Operations Mission, Thailand.*

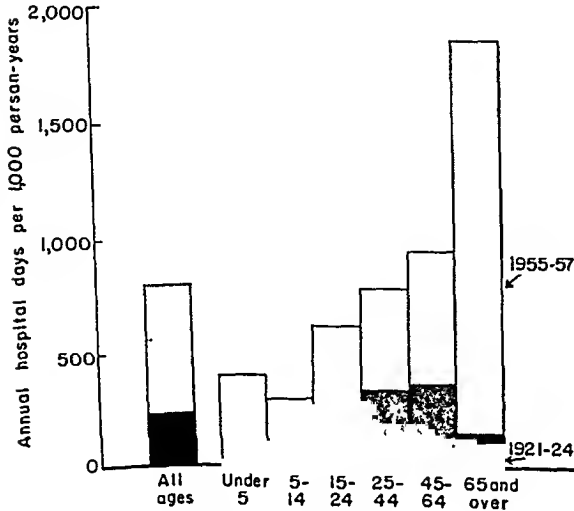

Table 1. Hospital admissions per 1,000 person-years of experience of populations surveyed in Hagerstown, Md., 1921-24 and 1955-57, by age group

Age group (years)	1921-24	1955-57	Times increased
Total-----	18	105	5.8
Under 5-----	9	67	7.4
5-14-----	21	58	2.8
15-24-----	23	115	5.0
25-44-----	21	139	6.6
45-64-----	19	87	4.6
65 and over-----	10	134	13.4

sions and in annual hospital days occurred among the youngest and the oldest age groups (table 1, fig. 2). Among children under 5 years, admission rates increased 7 times and annual days 10 times, while the comparable increases for persons 65 years old and over were 13 and 12 times. Each of the intervening age groups, however, also showed increases in hospital care.

Among the intervening age groups, increases in admissions tended to exceed increases in total days of care per year. Whereas admission rates rose by amounts ranging from just under three to almost seven times, total days of care in no case increased more than 2 to 2½ times. The differential between the increase in admissions

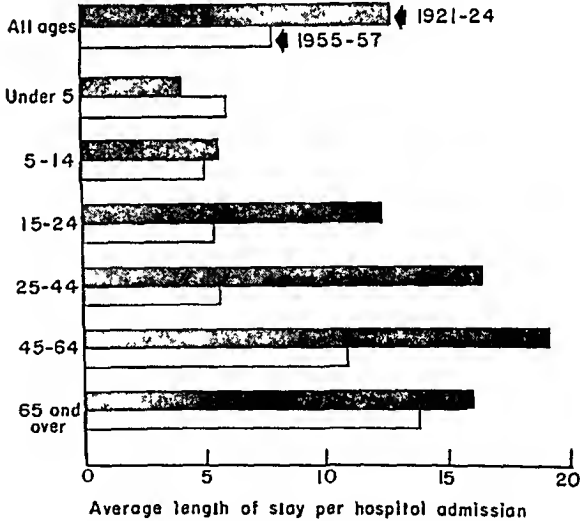

Figure 2. Annual hospital days per 1,000 person-years for populations surveyed in Hagerstown, Md., 1921-24 and 1955-57, by age

and the increase in days of care was greatest among persons 15-24 and 25-44 years old, and least among children 5-14 years of age. These differences reflect variations by age in the extent of change in average length of stay.

Although the average stay for the total survey groups declined about one-third, it decreased as much as two-thirds among persons 25-44 years old (fig. 3). Other age groups experiencing a marked decline were the 15-24 and 45-64. Relatively little change occurred in the shorter average stays of children under 15 or in the longer average stays of persons 65 and over. The small increase in stay among children under 5 can be explained at least in part by a decrease in the share of the caseload admitted for short-stay tonsillectomies.

Figure 3. Average length of stay per hospital admission for populations surveyed in Hagerstown, Md., 1921-24 and 1955-57, by age

Over the past 35 years the proportion of the Hagerstown population in the age groups having the highest hospitalization rates has increased. Between 1921-24 and 1955-57, the proportion of the surveyed population 65 years old or over doubled, rising from one-twentieth to one-tenth. There was an increase also in the second oldest group, 45-64, from about one-sixth to almost one-quarter of the total. The increase in hospitalization rates was sufficiently general among all age groups, however, that the

Hospital Use

Over the past 35 years, patterns of hospitalization in Hagerstown as reflected in use of the Washington County Hospital by the 1921-24 and 1955-57 surveyed populations have changed markedly. Perhaps the most striking change is the increase in hospital admissions and in total days of hospitalization per year.

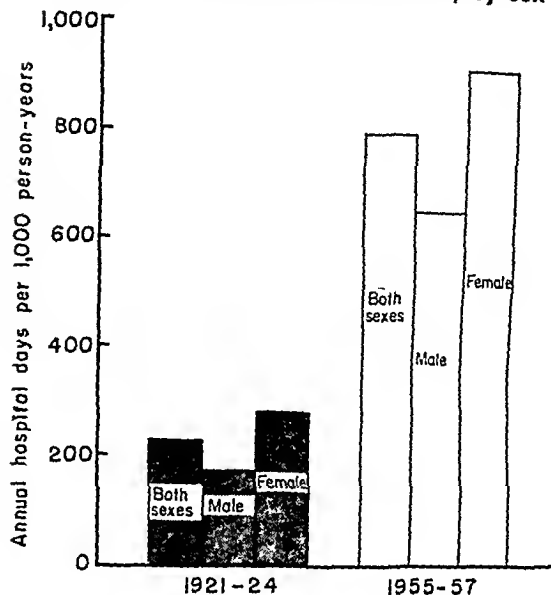

Hospital admissions among the 1955-57 surveyed population occurred at a rate about $5\frac{1}{2}$ times that for the 1921-24 group—105 per 1,000 person-years as compared with 18 per 1,000. Among females, who in both surveys had higher admission rates than males, the size of the increase was even greater—from 21 per 1,000 to 134 per 1,000, or a growth of more than 6 times. Admission rates among men increased about $4\frac{3}{4}$ times, from 15 per 1,000 to 71 per 1,000.

Patients in the more recent period tended to stay for shorter periods than did those admitted 35 years earlier. Whereas in the 1921-24 survey the average length of stay was 12.5 days, by 1955-57 the average had dropped to 7.6 days, a decrease of well over one-third. The decrease was particularly marked among females, whose average stay dropped from 13.2 to 6.9 days. Among males the decrease was proportionately smaller, from 11.5 to 9.2 days.

These decreases, however, only partly offset the increase in admissions in total effect on hospital days per year. So great was the increase in admissions that, despite the one-third decrease in average length of stay, total annual days of hospitalization received by the 1955-57 surveyed population exceeded by more than three times, relatively, the days of care received by the 1921-24 group. As shown in figure 1, the rate increased from 228 days per 1,000 person-years in the earlier period to 797 days in the latter. Among males the rate increased about $3\frac{3}{4}$ times as compared with a $3\frac{1}{3}$ increase in the rate for females.

Only a small part of the increase in hospitalization can be explained by a growth in the proportion of persons admitted more than once during a given year. The number of different individuals hospitalized increased from 17.3 per 1,000 persons to 91.3 per 1,000, or almost as much as the hospital admission rates. The increase in repeated hospitalizations was somewhat greater among females than among males.

Figure 1. Annual hospital days per 1,000 person-years for populations surveyed in Hagerstown, Md., 1921-24 and 1955-57, by sex

Hospitalization rates based on records of the Washington County Hospital slightly understate total hospital use to the extent that in both 1921-24 and 1955-57 certain members of the surveyed populations received all or part of their hospital care in hospitals outside Hagerstown. In the later period, as determined from interview replies, total admission rates, including "outside" hospitalizations, were about 10 percent higher than admission rates for the Washington County Hospital alone. There was some tendency for persons going to "outside" hospitals to stay for longer periods, raising the average length of stay from 7.6 days for Washington County Hospital admissions to 8.2 for all hospitalizations. Although it has not been possible to get similar detail on outside hospitalizations among the 1921-24 population, W. C. Dando, assistant to the administrator of the hospital, is of the opinion that the proportion so receiving care has not changed significantly in the past 35 years.

Variations by Age

Increases in hospitalization rates were found in all age groups, although the size of the increase was greater for some groups than for others. The largest increases both in admis-

mitted to the Washington County Hospital for deliveries at a rate of 7.2 per 1,000; in the 1955-57 population the comparable rate was 71.3 per 1,000, or about 10 times as great. Annual days of hospital care for deliveries increased at a somewhat lesser rate, reflecting an almost two-thirds decrease (from 12.9 to 4.7 days) in the average length of stay for delivery cases.

Birth statistics for the whole of Washington County support the hypothesis that the increase in delivery cases among the surveyed populations was related to a trend toward hospitalization for deliveries rather than to some other factor such as an increase in the birth rate. Between 1921 and 1956 the birth rate in Washington County scarcely changed; actually it decreased slightly. At the same

increase in age of the 1955-57 population accounts for only a small part of the overall increase in hospitalization. Even if the age composition of the population had stayed constant, as in table 2, annual hospital days relative to population still would have increased almost three times, hospital admission rates about five times, and persons hospitalized more than four times.

Diagnosis

It might be expected that a few outstanding diagnoses or diagnostic groups would account for most of the increase in hospitalization between the 1921-24 and 1955-57 survey periods. Actually there were increases in care, in terms of annual days of hospitalization or hospital admission rates, for practically every diagnosis or diagnostic group studied. This is shown in some detail in figure 4 and table 3.

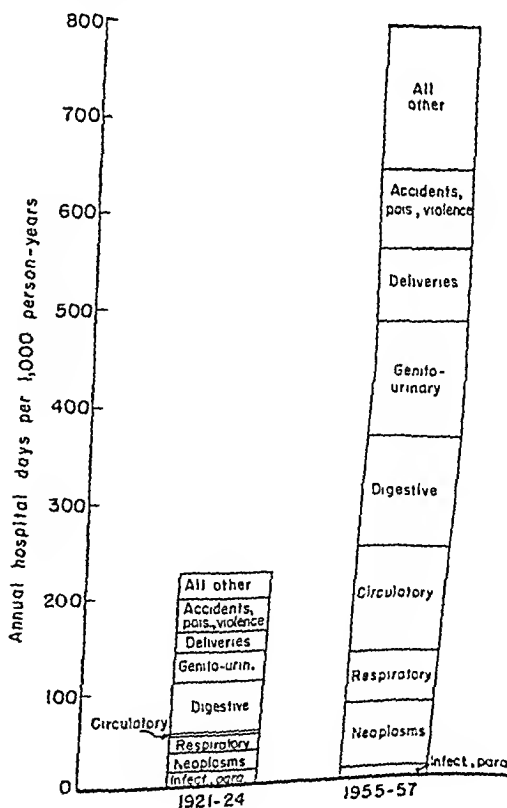

The diagnostic groups showing the largest proportionate increases in hospitalization were circulatory diseases (including heart), genito-urinary disorders, neoplasms, and deliveries. Such other categories as respiratory diseases, diseases of the digestive system, and accidents, however, also accounted for substantial increases in care. The only diagnostic group having a decrease in annual days of care was infectious and parasitic diseases, and this was surprisingly small.

Hospitalization rates for specific diseases or conditions within the diagnostic groups, al-

though based on small numbers of cases, provide similar evidence of a general growth in hospital use. Between the earlier and the later survey periods, only three diseases listed—tuberculosis, typhoid, and mastoiditis—disappeared as causes of hospitalization in this general hospital. Rates of care for appendicitis, tonsillectomies, and arthritis and rheumatism remained about the same or dropped somewhat. For all other diagnoses listed, hospital admissions and annual days of care increased by amounts ranging from twice to more than 50 times. Even pneumonia accounted for 2½ times as many admissions and annual days in 1955-57 as in 1921-24.

Increased hospitalization for the delivery of babies accounts for a significant part of the increase in hospital use among women of childbearing age. In the 1921-24 surveyed population, women 15-44 years old were ad-

Figure 4. Annual hospital days per 1,000 person-years for populations surveyed in Hagerstown, Md., 1921-24 and 1955-57, by diagnosis

1955-56 there were 6.7 deaths in Washington County Hospital for every 1,000 residents of the county, compared with 2.5 per 1,000 in 1922-23, or an increase of about 2½ times over the earlier period. As a proportion of total deaths among county residents, Washington County Hospital deaths rose from 10 percent in 1922-23 to 37 percent in 1955-56. The number of deaths per 1,000 episodes of hospitalization fell by about one-third (from 47.2 to 30.7 per 1,000) in connection with the large increase in hospitalizations that did not terminate in death.

Physician Supply

While hospitalization rates among the surveyed populations increased between 1921-24 and 1955-57, the relative supply of physicians remained about the same. The actual number of physicians in Washington County increased by about one-third, from 59 in 1923 to 82 in 1956, but this increase did little more than keep pace with the increase in the population during the period. The ratio of physicians to population scarcely changed, rising from 99 per 100,000 in 1923 to 104 per 100,000 in 1956. If the comparison is limited to physicians in private practice, the ratio is 99 per 100,000 in both periods. Any increase between 1923 and 1956 was almost entirely confined to physicians in public health, industrial medicine, and other positions distinct from private practice.

Most physicians in Hagerstown reportedly see more patients in a day or week today than they did some years ago. Not many of them work longer hours; on the contrary, most of them are said to have more real free time. Rather, the organization of practice has changed. More patients are seen in the office or at the hospital, and fewer in their homes. Where home calls are required, transportation is less of a problem. Also, according to Dr. E. F. Poole, the secretary of the Washington County Medical Society, there is more cooperation among physicians, whether informally or through partnerships or other organized arrangements, thus making services more readily available when needed.

Medical practice in Hagerstown resembles that in other parts of the Nation in that it has become increasingly specialized since the 1920's.

Whereas in 1923 only about one out of eight private practitioners in Washington County limited their practice to a specialty, by 1956 this share had grown to about one out of two (table 6). Special significance for hospital care trends can be found in the increased numbers of specialists in surgery, urology, anesthesiology, obstetrics, pathology, radiology, and other types of practice involving hospital service.

Hospital Beds

One of the factors related to the growth of hospital use in Hagerstown may have been the increase in the supply of hospital beds in the area. From 80-90 beds in 1922-23, Washington County Hospital's capacity grew to 268 beds in 1955-56. The ratio of beds to the population of Washington County increased from 142 to 340 per 100,000. But does this increase in beds necessarily mean that hospital admissions were facilitated?

Two facts suggest that the pressure on available beds in the Washington County Hospital was greater in the recent survey period than in the earlier period. First, between 1922-23 and 1955-56 the use of the hospital, as measured by

Table 4. Hospitalization rates¹ for women of childbearing age, compared with rates for men in same age groups, surveyed populations in Hagerstown, Md., 1921-24 and 1955-57

Males 15-44 years-----	13.4	52.5	3.9
<i>Annual days in hospital</i>			
Females 15-44 years:			
Including deliveries-----	416	1,058	2.5
Excluding deliveries-----	326	724	2.2
Males 15-44 years-----	204	349	1.7

¹ Per 1,000 person-years.

time, in the second half of this period alone, the proportion of all Washington County births occurring in a hospital increased about fourfold, rising from 26 percent in 1940 to 97 percent in 1956.

Even among women of childbearing age, however, the trend toward hospitalization for deliveries can be only one of a number of factors explaining the increase in hospital use. If we recompute the admission rates and annual days of care of women in this age group so as to exclude delivery cases, as shown in table 4, we find that over the past 35 years hospitalization for causes excluding deliveries increased almost as much as did hospitalization including deliveries. In both 1921-24 and 1955-57, moreover, women 15-44 years old were hospitalized at rates well above those of men in the same age category, whether or not deliveries are included.

Illness and Death Rates

Changes in hospitalization patterns can be expected to be related in part to changes in patterns of morbidity and mortality in the community. In Hagerstown, the incidence of certain chronic diseases is reported to have risen. There have been increases also in the proportion of persons dying from chronic illnesses and in the proportion of people dying in the hospital.

Because both the 1921-24 and the 1955-57 surveys had as their primary objective the measurement of illness rates, it is possible to compare changes in hospitalization rates with changes in reported sickness rates, at least for selected chronic conditions. Among the illnesses compared, the most common pattern of change was one of increase in both hospitalization and illness rates but the increase in hospitalization was greater. Thus the rate at which heart disease was reported in 1955-57 was approximately twice that for 1921-24, but during the same period hospital admissions and annual hospital days for this diagnosis rose 25 and 40 times respectively.

Evidence of change in causes of death in Hagerstown is found in death reports for the whole of Washington County in the years 1922 and 1956. Although the resident death rate for all causes showed only a slight decline (from 11.6 to 10.0 per 1,000 population), there was a noticeable shift from acute toward chronic illness in the cause of death, as shown in table 5. Infant death rates also were down by about two-thirds. Although information on deaths in other age groups is not available for years as early as 1922, between 1930 and 1956 alone the proportion of total deaths occurring among persons under 15 years of age declined from 15 to 8 percent, and the proportion among persons 45 years and over increased from 67 to 84 percent.

Deaths in the hospital in Hagerstown have increased in relation to total population although they have decreased in relation to the number of admissions to the hospital. In

Table 5. Resident death rates in Washington County, Md., by selected cause, 1922 and 1956

SOURCE: Maryland State Health Department.

1955-56 there were 6.7 deaths in Washington County Hospital for every 1,000 residents of the county, compared with 2.5 per 1,000 in 1922-23, or an increase of about 2½ times over the earlier period. As a proportion of total deaths among county residents, Washington County Hospital deaths rose from 10 percent in 1922-23 to 37 percent in 1955-56. The number of deaths per 1,000 episodes of hospitalization fell by about one-third (from 47.2 to 30.7 per 1,000) in connection with the large increase in hospitalizations that did not terminate in death.

Physician Supply

While hospitalization rates among the surveyed populations increased between 1921-24 and 1955-57, the relative supply of physicians remained about the same. The actual number of physicians in Washington County increased by about one-third, from 59 in 1923 to 82 in 1956, but this increase did little more than keep pace with the increase in the population during the period. The ratio of physicians to population scarcely changed, rising from 99 per 100,000 in 1923 to 104 per 100,000 in 1956. Whereas in 1923 only about one out of eight private practitioners in Washington County limited their practice to a specialty, by 1956 this share had grown to about one out of two (table 6). Special significance for hospital care trends can be found in the increased numbers of specialists in surgery, urology, anesthesiology, obstetrics, pathology, radiology, and other types of practice involving hospital service.

Hospital Beds

One of the factors related to the growth of hospital use in Hagerstown may have been the increase in the supply of hospital beds in the area. From 80-90 beds in 1922-23, Washington County Hospital's capacity grew to 268 beds in 1955-56. The ratio of beds to the population of Washington County increased from 142 to 340 per 100,000. But does this increase in beds necessarily mean that hospital admissions were facilitated?

Two facts suggest that the pressure on available beds in the Washington County Hospital was greater in the recent survey period than in the earlier period. First, between 1922-23 and 1955-56 the use of the hospital, as measured by

the number of patients admitted and total annual patient days, increased faster than did the ratio of beds to population. While the ratio of beds to population increased $2\frac{1}{2}$ times, hospital admissions increased almost seven times and the total annual patient days approximately quadrupled.

Second, the proportions of the hospital's available beds that were in use on any given day tended to be higher in the later period than in the earlier. In 1922-23 the average daily census represented about two-thirds of available beds. The 1955-56 average occupancy, in contrast, was about four-fifths of capacity.

In the later survey period, the availability in Washington County of some nursing home care may have slightly relieved the pressure for long-term hospital care of chronically ill or convalescing patients. Nursing homes were practically unknown in the county in the 1920's. In 1956-57, according to current State plans under the hospital and medical facilities construction (Hill-Burton) program, the county had 327 nursing home beds, with 250 admissions per year.

Socioeconomic Factors

Possible relationships between increased hospitalization rates and changes in socioeconomic status can be measured only in general terms, since there is no comparative information on the occupational and educational characteristics of the surveyed populations, and only a few such data for the population of Hagerstown as a whole. In Hagerstown, as in most other urban areas of the United States, the proportion of the working force in professional, technical, and related occupations has increased. More women are working. Educational levels have risen. These and other socioeconomic changes, which conform generally with national trends, have established a basis for increased popular appreciation of the value and convenience of hospitalization as compared with home care of the sick and injured. At the same time, throughout this period Hagerstown's basic character as a relatively self-sufficient trading center whose principal industries are manufacturing and railroading has remained substantially the same.

Insurance

Other studies have shown a relationship between hospital utilization and hospital insurance coverage. It is possible that in recent years the growth of insurance coverage has encouraged some people in Hagerstown to make greater use of the hospital than would have been made without such insurance. While the earlier Hagerstown survey was conducted before the establishment of the first hospital prepayment plan in the United States, by 1955-57 an estimated three-fifths of all Washington County Hospital patients had insurance and about three-fifths of the total bill to patients was being paid for by insurance. The average cost of care in the Washington County Hospital is about six times higher today than it was 35 years ago, having risen from \$3.15 per patient-day in 1923 to \$18.30 in 1956. This high cost of hospitalization has virtually required the development of insurance or some other means of spreading the financial burden over a wider segment of the population.

Related Findings

In overall magnitude the hospitalization rates for the surveyed populations in Hagerstown are roughly comparable to those found in similar populations of the same general time periods. The 1955-57 rates agree closely with rates found in the 1956 Public Health Service survey of general hospital use in the Nation, conducted by the Census Bureau (3). The Hagerstown survey's admission rate of 104.6 per 1,000 population, adjusted to 114.5 per 1,000 to include hospitalizations outside the Washington County Hospital, compares with a Public Health Service-Census survey rate of 117 per 1,000 for nonmetropolitan places with populations of 10,000 to 50,000. Average length of stay for the Hagerstown surveyed population (including outside hospitalization) was just over 8 days, ranging from 5 days to 14 days from the youngest to the oldest age groups. The average stay for cities of comparable size, as found in the Service's survey, was 7.2 days. While comparative information is not readily available for the earlier survey period, the use of the Washington County Hospital among the

1921-24 survey population was roughly similar in amount to the use of that hospital by the population of Washington County as a whole in 1922. Thus, annual days of hospital care in relation to population were only slightly higher for the county population than for the surveyed population. For both the Washington County residents and the 1921-24 surveyed population, average length of stay in the Washington County Hospital was about 12 days.

Summary and Conclusions

Two household morbidity surveys conducted by the Public Health Service in Hagerstown, Md., in 1921-24 and 1955-57, together with a concentration of hospitalization in one local hospital, provided the basis for a comparison of rates and patterns of hospitalization in the early 1920's and the mid-1950's. It was found that over this 35-year period, hospitalization rates in Hagerstown had increased three times in terms of annual days of care and $5\frac{1}{2}$ times in terms of admissions.

No single factor accounted for the increase in hospitalization. There was a small growth in the proportion of persons having more than one admission during a given year. The rate of hospitalization increased in all age groups, although the rate of increase was somewhat higher among children under 5 years and persons 65 years and over. The proportion of older persons in the population approximately doubled between 1921-24 and 1955-57.

There were increases in care for practically every diagnostic group studied. Only a part of the large increase in care among women of childbearing age could be attributed to an increase in hospitalization for the delivery of babies. Other diagnostic groups showing larger than average increases for all ages included circulatory diseases, genitourinary disorders, and neoplasms.

Average length of stay in the hospital decreased well over one-third between the earlier and the later surveys, but this decrease only partly offset the effect of increased admission rates in raising total hospital days. The greatest decrease in length of stay was among persons 25-44 years old. Very little change occurred in the lengths of stay of children under 15 and persons 65 and over.

One factor making for increased hospitalization probably was the increased occurrence of certain chronic illnesses, but for the particular illnesses studied the hospitalization rates tended to increase faster than the illness rates. Analysis of death rates showed that more people were dying of chronic diseases and that an increasing proportion of deaths were occurring in the hospital.

While hospital care increased, the supply of physicians relative to population remained about the same in 1955-57 as in 1921-24. The ratio of hospital beds to population was greater in the later period than in the earlier, but not enough greater to keep pace with the increase in hospital use. Hospital insurance coverage facilitated hospitalization in the later period to the extent that it paid for all or part of the hospital bills of about three-fifths of the patients.

The National Attack on Rheumatic Fever

AIMS C. MCGUINNESS, M.D.

WHILE we have made a great deal of progress against rheumatic fever, it is still a killer and crippler; it is still a national menace. Cold statistics give us an idea of its extent, but they can never measure the full tragedy, the hurt to the families whose children have been struck down with this disease. It has been estimated that about 2 million people living in the United States today have already had, or will develop, an attack of rheumatic fever at some time during their lives. Of these, more than 500,000 will probably die because of the rheumatic process or some complication developing directly from it. Rheumatic fever most often strikes children between the ages of 5 and 15, and the resulting rheumatic heart disease causes about 50 percent of all heart disease in this age group. I am told that in the 5- to 19-year age group in this country there is a current annual incidence of about 60,000 cases of rheumatic fever. About half of these are recurrences, and half first attacks.

The total economic waste caused by rheumatic fever in the general population cannot be even roughly estimated. But we do know that during World War II, rheumatic fever alone immobilized more than 400,000 men in the armed services, at a cost to the Government of about \$640 million.

We must never lose sight of our ultimate goal: the complete eradication of this killer and crippler. Let us hope that the progress we have made will whip us into even further—and unrelenting—efforts. I think it will.

The concerted national attack on rheumatic fever, in which the Federal Government plays an important role, has shown spectacular growth since it began less than a decade ago. Rheumatic fever and rheumatic heart disease are, of course, a major concern of the National

Heart Institute, Public Health Service, and research support in this area has increased more than tenfold since 1949 to a current total of around \$1.5 million annually. The institute conducts a substantial research program of its own in Bethesda, but devotes most of its funds to the support of cardiovascular research in hospitals, universities, medical schools, and other institutions throughout the country.

The institute's research grant program in rheumatic fever and rheumatic heart disease is helping scientists approach the problem from many different directions. Population studies are bringing in new knowledge of the movement of streptococcal infection among families and individuals. Scientists are also trying to find out more about the nature of immunity from these infections.

One of the most urgent needs in this field is for more fundamental knowledge of the intricate cellular events and mechanisms of connective tissue, the target of rheumatic fever. For this we need more intricate equipment and more highly skilled workers.

Since the most widely accepted theory of the nature of rheumatic fever is that it is an allergic reaction of certain of the connective tissues to some substance given off by the streptococcus—the cause of streptococcal infections—attention is being focused on the biochemical and biophysical mechanisms involved in allergic responses, and attempts are being made to identify the streptococcal substance to

Dr. McGuinness is special assistant for health and medical affairs to the Secretary of Health, Education, and Welfare. The paper is part of the Harry Remer Memorial Lecture delivered by Dr. McGuinness on June 14, 1959, at La Rabida Sanitarium in Chicago, Ill.

which approximately 3 percent of all children between the ages of 5 and 12 seem to be allergic.

Gains in Research

As has often been the case, victory over a disease may be greatly speeded if it can be produced experimentally and studied in animals. For many years, rheumatic fever research has been hampered by inability to produce it in the laboratory. But now scientists believe they have achieved this. Rabbits given repeated injections of streptococci have developed heart defects similar to those of rheumatic heart disease. If further research bears this out, the work should serve as a valuable springboard.

Drug studies are of paramount importance, because we do not as yet have an ideal drug or drug combination for treating rheumatic fever itself. We now know that ACTH and cortisone, at least in the smaller doses used in early studies, are no more effective in treating rheumatic fever than aspirin. We found this out from a very valuable international study conducted in 13 hospitals in the United States, Canada, and Great Britain with the aid of the National Heart Institute. Dr. Albert V. Dorfman and his group at the La Rabida Sanitarium are, I understand, analyzing statistically the first results of a large-scale study they have made of hydrocortisone therapy in rheumatic patients, in which substantially larger doses of drugs have been used.

We now have enough knowledge about the control of rheumatic fever to make possible an adequate and thorough program of preventing it in any community.

Services for Children

Developments in the treatment of children with congenital heart malformations in the last two decades have been truly dramatic. The number of children who were previously doomed to an early and inevitable death has been drastically reduced by the development and use of a wide variety of surgical techniques.

Since 1939, the Children's Bureau through its crippled children's program has been offering children with rheumatic fever medical help

that may limit the impairing effect on their later productive lives. At present, all but one State offer services to children with rheumatic heart disease in the crippled children's programs which have developed as a part of the Federal-State partnership.

More recently, the Bureau, with the cooperation of the States, has developed ingenious patterns to make complicated heart surgery available to the maximum number of children with congenital heart defects who can benefit from such surgery. Not only through the regular crippled children's programs but through five regional heart centers as well, children are now receiving surgery for congenital heart malformations which for many of them can make the difference between life and death. The number who have been served under this part of the crippled children's program increased from 2,000 in 1950 to 10,000 in 1957. In the meantime, a variety of surgical techniques, most recently open-heart surgery, have been developed. As a result the number of congenital heart conditions which are operable has increased. At the request of the administration, Congress recognized this development during the current session by appropriating \$1.5 million above regular funds for the crippled children's programs to be used especially for these lifesaving heart malformation operations.

Prevention and Control

Illustrative of another approach to the prevention of rheumatic fever is the drive conducted jointly several years ago by the National Heart Institute and the American Heart Association. It made an important contribution. Various aids for physicians and other health workers, such as folders giving the latest diagnostic criteria and treatment recommendations, were sent to every physician in the United States.

Another branch of the Public Health Service, the Bureau of State Services, has played an important part in the national attack on rheumatic fever through its Heart Disease Control Branch. This branch assists States and localities, both through financial grants and assignment of people with special technical skills when they are needed, in establishing and im-

proving heart disease control activities. The establishment of rheumatic fever registers and prophylaxis programs and the development of better rheumatic heart disease diagnosis and casefinding methods are of course vitally important.

In Chicago a new study was started in April 1959 to test the practicality of mass screening as a way of finding children who should seek medical attention for possible heart defects, including those caused by rheumatic fever. A special tape-recording device, developed by the Chicago Heart Association, is being used. The study, in which the heartbeats of 40,000 fourth-grade school children will be recorded, will aid health workers in finding out what problems may be involved in large-scale screening programs of this kind and will also provide data on the number of children with undetected heart defects.

Guiding the project with the Public Health Service is an interagency committee composed of representatives from the Chicago Board of Health and Board of Education, the Chicago Medical Society, the American Heart Association, the Children's Memorial Hospital, the parent-teachers association, and several universities. Since the outlook for children with heart abnormalities is much better if their condition is diagnosed and treated early, the adoption of faster and less expensive methods of finding early cases would certainly save many lives.

Recently, exploration of another promising and rather novel possibility—the use of an electronic computer as an aid to the physician diagnosing cardiovascular disease—was begun by the Heart Disease Control Branch. The basic idea is to develop a computer into which all pertinent objective data could be fed, such as data concerning the electrocardiogram, the phonocardiogram, the ballistocardiogram, and the arterial pulse, together with such factors as age, sex, height, weight, and blood pressure. The computer would then indicate to the physician the probability of specific heart diseases or injuries.

These, of course, are only illustrations of the work affecting the rheumatic fever problem that the Heart Disease Control Branch is aiding. The encouragement and help that it has given State and local health departments to establish and enlarge rheumatic fever programs has been one of the major factors in the tremendous growth of this nationwide endeavor.

The number of States assuming a responsibility for either or both prevention and treatment of rheumatic heart disease increased from 12 in 1950 to 40 in 1958. Also, the number of States now engaged in the distribution of free or low-cost prophylactic drugs has increased from 2 in 1950 to 29 in 1958. A number of the remaining States that have not yet developed programs are encouraging rheumatic fever and rheumatic heart disease control efforts both in local health departments and in nonofficial agencies. These facts certainly show a great public awakening to the problem in this decade.

Along with this awakening to the problem in this and other areas of health research has come some concern that today's large Federal grants in the field of medical research are stifling private giving in the field of health. The fact is that nothing could be farther from the truth.

Support for medical research from all sources jumped from \$88 million in 1947 to about \$450 million this year. Of this \$450 million, the Federal Government contributed approximately half, and the balance came from industry, endowment, and private philanthropy.

In June 1958 a group of consultants on medical research and education, headed by Dr. Stanhope Bayne-Jones, made their report after an exhaustive nationwide study. I was particularly interested in this comment in the report: "Americans have always banded together voluntarily to accomplish certain commonly valued objectives. This has been particularly evident in the health field. . . . Humanitarian sentiments and religious doctrines that foster respect for life and for the individual, combined with respect for science, will engender continuing and strong support for medical research from both public and private sources."

Nutritionists aid staff members of an organized home care team in recognizing and interpreting the importance of diet in the care of patients with long-term illness.

The Nutritionist in Organized Home Care

MILDRED KAUFMAN, M.S., and MARIAN S. BRYAN, M.S.

THE NUTRITIONAL NEEDS of the chronically ill too often are considered only when a therapeutic diet is required. Nutrition service is commonly believed adequate if diet instructions have been given in the hospital or if the physician has provided the patient with a diet list.

Thoughtful observers will quickly recognize that this approach ignores the dynamic role of nutrition in the patient's improvement, rehabilitation, or recovery. Even the most clearly written diet instruction sheet is not effective in motivating patients to change or improve the eating habits of a lifetime. The nutritionist in organized home care plans gives other team members stimulation and guidance in developing the knowledge, skills, and techniques to recognize nutritional needs and to assist patients and their families in achieving and maintaining an appropriate diet.

Nutritionists, as an integral part of organized home care programs, have a valuable contribution to make in the treatment of patients with long-term illness.

Organized Home Care

Organized home care programs have developed in a number of communities as an answer to the mounting problem of providing comprehensive care to patients with long-term illness (1). These programs coordinate the various skills of the medical care team and bring them to the patient at home. The trained

workers who provide the skilled services also teach family members to perform some of the simpler procedures needed for care of the patient. Through this plan, the patient receives the professional care and supervision he requires while remaining a part of his family and enjoying the comfort and security of his own home. The family continues to provide such basic essentials as food, shelter, laundry, clothing, and other necessities (2).

As specifically defined, "Organized home care provides coordinated medical and related services to selected patients at home through a formally structured group comprising at least a family physician, a public health nurse, and a social caseworker assisted by clerical service. For satisfactory functioning, patients must be formally referred and there must be an initial evaluation, monthly review of records, and a final discharge conference. There must be ready access to inpatient facilities." This definition was agreed upon at the Roanoke conference on organized home care which was sponsored by the Public Health Service in June 1958.

Organized home care programs now in operation are administered by hospitals or such agencies as visiting nurse associations and local

Both the authors are nutrition consultants, Miss Kaufman with the Chronic Disease Branch, Division of Special Health Services, Public Health Service, Washington, D.C., and Miss Bryan with the Visiting Nurse Society of Philadelphia, Pa.

health or welfare departments. Administration and services vary with the agency from which the program operates. Regardless of the administration or agency, the services should be planned around the care needs of the patients. The above definition, as well as a review of the existing programs, indicates that the minimum services considered essential are medical, nursing, and social services, and provision of drugs and supplies. Services considered desirable are physical and occupational therapy, homemaking, health education, and nutrition (3).

Nutrition Needs in Long-Term Illness

In considering the needs of patients, optimal nutrition is emphasized as one of the most important environmental factors affecting health. However, nutrition is one area which professional workers might easily overlook if their attention is not directed to it, since the family of the home care patient assumes the responsibility for planning, preparing, and serving his meals.

The kind and quantity of food that will meet his individual needs are essential for each patient. An inadequate diet must be improved to provide an optimal level of nutrients. Special needs require increases above normal nutrient requirements, to help fight infection, or to heal wounds, decubiti, and fractures, or to aid recovery from an anemia. Reducing the obese patient and bringing the underweight up to normal weight often are essential steps in rehabilitation. Correction of constipation through diet can reduce the use of medication and the need for routine enemas. Diabetes, cardiac disease, gastrointestinal disorders, liver or gall bladder disease, or other medical conditions require modified diets, and chewing or swallowing difficulties require changes in the consistency of food.

Whether a therapeutic diet or improvement in the nutritional quality of the diet is ordered, the patient and his family almost inevitably need and desire some guidance in their meal planning. Often there is need for improvement of the nutritional value of the entire family diet.

Because good nutrition can contribute to the

vigor, well-being, and therapy of the patient, dietary guidance should be an essential part of a well-organized home care plan.

Role of the Nutritionist

The role of the nutrition consultant in the Philadelphia Home Care Plan illustrates how nutrition services can be integrated into an organized home care program. Administered by the Visiting Nurse Society of Philadelphia, this program is a special service within the agency (4). For many years the society has employed a full-time nutrition consultant to help the nurses plan for the nutritional needs of their patients and to participate in student and staff inservice education. When the plan was organized in 1949, it was recognized that the nutrition consultant should be a member of the team and that part of her time should be devoted to home care activities.

The team includes the patient's physician, medical consultant to the plan, nurse coordinator, staff nurse, social worker, physical therapist, occupational therapist, occupational health consultant, as well as the nutrition consultant. At team conferences, candidates are evaluated for admission and plans are made for the care, treatment, and rehabilitation of the patient. At this time, the patient's needs and the contributions of various services are coordinated. The patient's progress is reevaluated periodically at subsequent meetings.

The nutrition consultant interprets to the team the dietary goals desirable for the patient. Dietary guidance is thus coordinated with the other home care services, placing nutrition in its proper perspective. With conference planning, followed by consultation, it is possible for team members who work directly with the patient to integrate nutrition advice into patient contacts and so strengthen diet teaching.

A consultant seldom has direct contact with the patient. She is dependent upon others for background and insight concerning the patient and his home situation. The reports of various team members frequently identify factors motivating family behavior, which must be considered in planning for any workable diet regimen. Time is saved and duplication of effort is avoided by early recognition

at the team conference that nutrition is an important aspect of the total plan for care.

Whether or not giving direct service to patients is the most effective use of the nutritionist's time is a decision to be made within the home care program. Factors affecting this decision might be the number, interest, and preparation of other staff workers to do dietary teaching.

To function as a team member, a well-planned orientation for the nutritionist is vital. She should fully understand the philosophy and objectives of the home care program and how to plan for the nutritional needs of patients in their own homes. It is essential that she work closely with the other team members, and to do so, she should feel comfortable as part of the group and appreciate what each of her co-workers is trying to do. In turn, the nutritionist should make sure that all workers understand her function and the importance of good nutrition to the patient. In achieving these goals, the nutritionist should be active in in-service staff education and have assurance of the support of the program administrator.

Case History

The story of a 27-year-old patient shows how this program operates and how the nutritionist contributes. For this discussion, the patient is called Jane Green.

Jane was admitted to the Philadelphia Home Care Plan in November 1957, after a year of treatment in a large city hospital. Her illness had been diagnosed as Pott's disease, with paraplegia.

As a basis for the first team conference at admission, the patient's physician submitted a medical referral form which reviewed her physical condition and gave orders for nursing care, physical and occupational therapy, and a 2,500 calorie diet with 125 grams of protein. Jane's public assistance visitor was included in the initial conference.

Workers who had visited Jane for evaluation described her as intelligent and cooperative but discouraged because she was bedfast. She complained of weakness and fatigue to each of them. Jane's mother, with whom she lived, took care of the home and meal preparation.

The team concluded that getting about in a wheelchair would be a minimum goal for Jane, but she might achieve ambulation with braces and a return to some gainful employment. It was felt that the patient's poor nutrition contributed to her chronic state of fatigue, an obstacle in achieving the maximum goal. The patient was quoted as stating that she had "a poor appetite," "ate poorly in the hospital," and "could not eat much at home." The physician had told Jane to "eat more protein." Mrs. Green thought this meant expensive cuts of meat and complained that she was unable to afford the diet ordered.

As a result of the conference, the public assistance worker obtained from the physician a request for an additional financial allowance for the prescribed diet. The nutrition consultant suggested that the nurse ask the patient to keep a food-intake record as a more objective criterion in evaluating Jane's current diet. Questions about food habits and home conditions identified areas for the staff nurse to investigate before dietary guidance could be planned.

Shortly after this conference, the nutritionist and nurse met to discuss Jane's diet. Jane's food-intake record showed that she was eating only two meals a day and small servings of selected foods. She was eating much less than the 2,500 calories and the 125 grams of protein prescribed, and her food intake failed to meet recommended dietary allowances for other nutrients (5).

Since the prescribed diet did not appear immediately practical, as Jane could not eat large quantities of food, a phone call was made to Jane's physician to inform him of dietary findings. He recognized the problem but, because of the nature of Jane's illness, stressed her need for the prescribed protein intake, optimal levels of other nutrients, and calories to provide gradual weight gain of 10 pounds. He urged that an acceptable diet be planned for Jane, working toward the diet prescription gradually, and asked for reports of progress.

Together the nurse and nutrition consultant prepared a diet plan for Jane considering the diet prescription, her appetite and food preferences, and her mother's limited cooking skill. The plan suggested amounts of specific food

groups to provide about 2,000 calories. A supplemental list specified foods which could be added gradually to bring the diet up to prescribed levels as Jane's appetite increased. Jane had agreed to cooperate, stating that she was anxious to do anything that would contribute to her well-being. Written copies of the diet plan were given to the patient, sent to the physician, and kept in the records of the nurse and nutrition consultant. At the request of Mrs. Green, simple recipes were supplied for the foods listed on the diet, particularly some using nonfat dry milk which the family received as a surplus food commodity.

Reevaluation of the patient's food intake at 2 and 4 months following the initial diet instruction showed considerable improvement. Nurse's notes on successive visits showed that Jane was eating three meals a day regularly and was using an increased amount and variety of foods. However, she still needed more foods rich in vitamins A and C. Jane made a real effort, but constant support and encouragement were required to help her continue with the diet. She said that she was enjoying her food more at home. Mrs. Green had tried some of the recipes the nurse had given to her, and she catered more to Jane's taste than would be possible in the hospital. At the end of 4 months, Jane had gained 6 pounds; she was feeling better and was not as weak and tired as she had been.

Diet plans for Jane had been discussed with her physical and occupational therapists, and they were asked to lend encouragement. The physical therapist reported after 4 months that Jane expressed concern about gaining too much weight. She had explained to Jane that as her food intake was increasing her physical activity was also increasing; that her weight gain so far was satisfactory but when she reached the desired weight, the calorie intake would be modified.

Nine months later at the final evaluation conference, it was reported that Jane was walking with braces, getting around the house, and going outside. Employment possibilities outside the home were being explored with the help of the occupational health consultant. Everyone expressed pleasure with the patient's progress and agreed that improved nutrition was a prime

factor in achievement of the treatment goals for this patient.

Use of Nutrition Services

As has been stated, in the Philadelphia program the nutrition consultant attends all of the team planning and evaluation conferences. Individual consultations to give dietary guidance for the patient are held at the request of the nurse or other team member. Requests were made for nutrition consultation on behalf of 95 (49 percent) of the 194 patients admitted from June 1, 1957, to May 31, 1958 (see table).

It will be noted that nutrition consultation was not requested for every patient. Some patients or their families were unable to accept any dietary modification. A few patients died shortly after admission. And in a number of instances, it was felt that an experienced staff nurse had sufficient background to provide suitable dietary guidance without consultation.

With a changing caseload, the demands for nutrition consultation vary from week to week. The nutrition consultant has a flexible schedule and can devote more or less time to home care as needed. She estimates that in an average week she devotes about 6 to 8 hours to individual and team conferences on behalf of patients receiving home care.

Other Patterns

The Philadelphia Home Care Plan has been used to illustrate how a nutritionist in one organized program provides dietary guidance for its patients. It is emphasized, however, that the nutritionist should tailor her service to the individual program and offer to serve in the way that will be most effective for the patients and staff.

Some hospital-based programs utilize the services of their own hospital dietary department. This can be developed in a dietary department which has a well-trained staff with an active patient education program. If the dietitian has initiated diet teaching in the hospital or clinic, she then can follow progress and offer continuing guidance by working with the staff members who visit the patient at home. Since dietary problems of patients at home are

Nutrition consultation in the Philadelphia Home Care Plan, June 1, 1957-May 31, 1958

Diagnostic classification	Patients admitted	Patients for whom nutrition consultation was provided	
		Number	Percent of patients admitted
Cerebral vascular accident.....	99	44	44.4
Neurological disorders.....	26	11	42.3
Arthritis.....	25	16	64.0
Cancer.....	7	4	57.1
Fracture.....	20	7	35.0
Heart and other circulatory disorders.....	5	2	40.0
Diabetes.....	8	7	87.5

Other.....	2	2	100.0
Total.....	194	95	49.0

somewhat different from those of hospital patients, the hospital dietitian, working in a home care program and as a member of the home care team, must be oriented by observation and experience to the type of patients cared for by the program and the kinds of homes in which they live. Information concerning diet should be shared with the staff of any of the community agencies who may be providing related services to patients receiving home care.

A number of medical schools have organized home care programs which are used for the training of students. In such programs, a nutritionist can present a dietary teaching program as part of professional education. She can participate actively in team planning and evaluation conferences and, when working directly with patients and their families, demonstrate dietary teaching methods to the students.

In programs that cannot budget a full-time staff nutritionist, it has been possible to "borrow" these services from another health agency.

A nutritionist in a cooperating private agency, in the local or State health department, or on the dietary staff in a cooperating hospital is a possibility. With a limited budget, it also might be possible to employ, on a part-time basis, a qualified nutritionist or dietitian living in the community. When utilizing nutrition service from another agency or on a part-time basis, realistic arrangements must be made to provide continuing service and sufficient time for full participation in conferences.

Conclusion

Nutrition services in an organized home care program may be provided effectively in a number of ways, but the main objective is to help each patient achieve and maintain the diet which best meets his needs, with the least difficulty for him and his family. This objective can be accomplished when the diet teaching plan considers the patient's social, emotional, and financial situation as well as his physical problems; when diet is the concern of all workers attending the patient; and when changing dietary needs are a part of the comprehensive plan for care.

Progress in Reporting Mental Hospital Statistics

*Ninth Annual Conference of
Mental Hospital Statisticians
Albany, N.Y., May 5-7, 1959*

THE USE of revised terms to define the movement of mental hospital populations, plans for an interstate cohort study of mental hospital admissions, statistical activities of community mental health programs, and new techniques of reporting mental hospital expenditure data were emphasized at the Ninth Annual Conference of Mental Hospital Statisticians.

The conference, held in Albany, N.Y., May 5-7, 1959, is sponsored annually by the National Institute of Mental Health, Public Health Service.

Delegates from each of the 21 member States of the Model Reporting Area for Mental Hospital Statistics attended (see box insert). Observers from Delaware, Iowa, Massachusetts, North Carolina, and Tennessee were also present, as well as representatives from the Dominion of Canada, the Veterans Administration, and the American Psychiatric Association.

Use of Revised Definitions

New terms describing the movement of mental hospital populations were defined and adopted at the Eighth Annual Conference of the Model Reporting Area in Sacramento, Calif., in May 1958. Subsequently, the director of the mental hospital program in each of the Model Reporting Area States approved these definitions and indicated that the statistical system would be able to incorporate them into its reporting procedures at the beginning of the fiscal year 1960.

The revised definitions differ from those previously used in two major respects: (a) the

concepts of first admission and readmission have been replaced by substituting a classification of admissions according to type of hospital in which the patients had previous inpatient experience for mental disorders, and (b) the definition of a State system has been expanded to include public institutions for the mentally deficient, for purposes of distinguishing between discharges and transfers.

A set of schedules, based on the revised definitions, was proposed for the annual reporting of data to the National Institute of Mental Health by States in the Model Reporting Area as follows:

1. Movement of population by sex.
2. Movement of population by age, sex, and mental disorder.
3. Movement of population by time on books (time in hospital plus time on leave), sex, and mental disorder.
4. Admissions with no record of prior admission in any inpatient psychiatric facility, by age, sex, and mental disorder.
5. Admissions with prior admission to hospitals in the same State system only, by age, sex, and mental disorder.
6. All other admissions by age, sex, and mental disorder.
7. Resident patients at end of year by age, sex, and mental disorder.
8. Personnel employed at end of year.
9. Financial statement.

The suggested schedule for movement of population by sex is considerably more detailed than the one in use. While the current form balances the book population of the hospital

only, the new form covers both items affecting the resident population and those affecting the population on leave. The admission section of this schedule is divided into the following categories:

1. Admissions with no record of prior admission to an inpatient psychiatric facility.
2. Admissions with prior admission to hospitals in the same State system only.
3. Admissions with prior admission to other inpatient psychiatric facilities only.
4. Admissions with prior admission to facilities in both the same State system and other inpatient psychiatric facilities.

Discharges on this schedule are classified as:

1. No further treatment indicated.
2. Against medical advice.
3. Treatment in another facility intended.

It was agreed that this classification would be optional since discharges cannot be so classified in some State systems.

Data on the movement of population by age, sex, and mental disorder and by time on books, sex, and mental disorder have been prepared in only one State. Such data are basic to an understanding of the dynamics of a hospital population. They permit the computation of annual net release and death rates specific for age and for length of time on the hospital rolls.

Rates have been computed according to these variables for a single hospital and have revealed pronounced variations by age, diagnosis, and length of time on books. Studies of trends in these specific indexes can pinpoint the various elements of the hospital populations in which significant changes in the movement of patients are occurring. These studies can also assist in evaluating new therapies and treatment programs as well as changes in administrative policies.

Nationally, consolidation of mental hospital data will pose some problems in that 21 States will be reporting by one set of definitions and the remaining States by another. However, the first year's experience gained by the Model Reporting Area States will be of great assistance to the States not in the area as they convert to the new definitions. It is expected that within 2 years most of the States will be reporting nationally by preparing the same set of tabulations.

Cohort Studies

The report of the first cooperative interstate cohort study entitled, "Patterns of Retention, Release, and Death of First Admissions to State Mental Hospitals in 1954," soon to be published as a monograph, stimulated interest in additional interstate cohort studies. A cohort study committee, appointed at the eighth annual conference, presented its report at the ninth annual conference. The committee indicated that a further cohort study would allow control of certain factors which were not controlled in the first study, hopefully permitting the discovery of further factors responsible for interstate differences in probabilities of release, retention, and death. Analysis of cohorts of admissions for several States should provide a more meaningful picture of the course of hospitalization for mental illness than a study done in a single State.

Discussion of specific questions a new cohort study could answer revealed a major interest in the following:

1. What proportion of a study cohort is in the hospital, has died, or is out of the hospital at certain anniversary dates after admission?
2. What is the probability of first significant release from the hospital within specified intervals of time after admission?
3. What is the probability of return to the hospital within specified intervals of time after release among a cohort of patients who have had a first significant release?

Relationships between these probabilities and such factors as age, sex, diagnosis, marital status, race, legal status, and place of residence could be investigated. Interstate differences in

Model Reporting Area States

Representatives from the following States are members of the Model Reporting Area for Mental Hospital Statistics:

Arkansas	Louisiana	Oklahoma
California	Michigan	Pennsylvania
Connecticut	Minnesota	South Carolina
Illinois	Nebraska	Texas
Indiana	New Jersey	Virginia
Kansas	New York	Washington
Kentucky	Ohio	Wisconsin

the results would answer certain questions about State mental hospital programs and might raise other questions which should be investigated by definitive studies.

A discussion revealed that a variety of cohort studies are in progress in the various Model Reporting Area States. However, the questions under investigation in these studies, the variables being controlled, and the endpoints being used varied considerably. It was agreed, therefore, that a retrospective study would not be feasible.

It was proposed that a prospective study be conducted beginning with patients admitted July 1, 1959. The prospective study would consider three major questions, the determination of the status of each patient on specified anniversary dates after admission, the probability of significant release or death within specified periods of time after admission, and the probability of return to the hospital within specified periods of time after significant release among cohorts of released patients. Status on anniversary dates would be classified as in hospital, died in hospital, or absent from hospital. To answer the second question requires the determination of intervals of time between date of admission and date of death in the hospital or first significant release. To answer the third question requires the computation of intervals between date of first significant release and date of first return to the hospital. It was agreed that second significant release and second return to the hospital would also be considered. A significant release is defined as one from which the patient is not expected to return and includes direct discharges, trial visits, and escapes of over 30 days' duration.

Each State participating in the study would be required to use a standard punchcard layout and a standard code. Analysis of the data would then be made at a central point, using electronic computing equipment. Specific definitions and rules regarding the mechanics of the study were discussed and approved by the conference members.

Community Mental Health Programs

A panel discussion on community mental health programs was conducted by representa-

tives from four States operating such programs. These States are New York, New Jersey, Minnesota, and California. As described, the programs appear to be quite similar. In each of the four States, the programs are a local responsibility and under local control. In order to qualify for State funds, however, the programs must meet certain standards. Once it has been determined that these standards have been met, the State matches local expenditures up to 100 percent. However, each State law, with the exception of California, defines the amount which the State will spend annually per capita population.

Services for which community mental health funds are available include outpatient psychiatric clinics, inpatient psychiatric facilities of general hospitals, psychiatric rehabilitation services, such as workshops and aftercare clinics, and consultant and educational services to schools, courts, health and welfare agencies, and the like. The type and extent of these facilities vary from State to State.

There was general agreement that community mental health programs have done much to stimulate local interest in mental health. However, relatively few data have been collected on various aspects of these programs in an attempt to evaluate them. Each of these States is collecting some information on outpatient clinics, but only one is obtaining any data on the inpatient and rehabilitation aspects of its program. It was pointed out in the discussion that determination of the effect of community mental health programs requires systematic data collection and analysis as early as possible. If such data collection systems are not begun soon, it will be extremely difficult to measure the impact of these various efforts on the total community mental health program.

Mental Hospital Expenditures

Over the past several years much interest has been expressed in the development of more adequate data on mental hospital expenditures. The consensus has been that the expenditure data collected and published by the National Institute of Mental Health have not been comparable from State to State. The eighth an-

annual meeting of the Model Reporting Area recommended that the NIMH Biometrics Branch call together a committee of statisticians and administrative-fiscal people from several State mental hospital systems to discuss ways of obtaining better interstate comparison of expenditure data. Such a committee met in February 1959, and a report of the meeting was given at the conference.

To date, interstate comparisons of expenditures for the care of mental hospital patients have been based almost solely on expenditures for maintenance per patient per day. Problems are inherent in both the numerator and the denominator of such a ratio. Differences among States in accounting procedures and lack of uniform definitions of items to be included in the total maintenance expenditures have resulted in noncomparable total expenditure figures. Furthermore, the use of the average daily resident patient population as a denominator introduces an element of non-comparability into the ratios because of wide variations among State systems in the composition of the resident patient populations. It was agreed, therefore, that this type of ratio could not be used to answer questions relating to the cost of care of specific segments of the hospital population.

The committee further agreed that a classification of the total amount spent per year by a State mental hospital system for the mentally ill according to each of two axes, object and function, would provide much more meaningful information than currently available. The following items were included in the classification by object: personal services (salary and wages), food, utilities, medical and hospital supplies, clothing, household supplies, communications, travel and subsistence, new equipment, repairs and replacement of equipment, repairs to plant, farm supplies, office supplies, miscellaneous supplies, and patient services in the community. The function classification included inpatient care, outpatient care (including followup services), research, training, and central office.

The group agreed that a cross tabulation of these two classifications for each State would provide more useful data than are now available. However, it was recognized that each of

these categories requires careful definition. Since this would require a considerable amount of research, it was agreed that the task could not be accomplished by the committee. It was suggested that an application for a grant be prepared by a committee of business managers, accountants, statisticians, and medical administrators to finance a study in which these definitions could be developed. This would involve studying the accounting systems in several State mental hospital systems, testing the definitions finally developed, and obtaining the approval of the commissioners of mental health. Subsequent to the committee meeting, the possibility of sponsorship for such a project has been investigated, and it appears likely that a study design will be formulated within the next year.

Hospital administrators frequently have been asked to indicate the cost of care of specific groups of patients, such as children or those 65 years of age and over. The committee indicated that accounting systems are not currently set up to answer such questions. It was recommended that a project be developed in a few State systems in which the cost of caring for patients 65 years of age and over might be determined on a sampling basis. Such a study might be useful to other State systems in making inferences about their own costs for such patients.

Consideration was given to fiscal data which the National Institute of Mental Health should publish routinely. It was recommended that it might be feasible for NIMH to publish not only expenditures per patient per day but also expenditures per patient under care during the year. Turnover in the hospital population during the year would be taken into account in the latter and, when used in conjunction with the former, would provide more meaningful information than is currently available.

Other Problems

The perennial problem of the need for a more adequate classification of mental hospital personnel was discussed. It was agreed that this problem cannot be solved by statisticians alone and the assistance of personnel officers should be enlisted. The NIMH Biometrics Branch

agreed to organize a committee of personnel officers and statisticians which will meet prior to the next conference to discuss the problem and propose solutions.

Several administrators of mental hospital programs have expressed interest in evaluating the effectiveness of their programs. This stems from an increasing demand by State legislatures for information on the results achieved through expenditures for hospital construction and maintenance and for the care of patients. Thus far, only crude data on movement of hospital populations and on the experience of cohorts of first admissions have been available. While these data have provided partial answers to the questions raised by the administrators, many other important questions have remained unanswered. A description of a project underway to design a tool for measurement of mental hospital effectiveness served as a focal point for discussion of this problem. Several of the participants indicated interest in testing such a tool in their own hospital systems once it has been developed.

Regional Meetings

A report covered the Fourth Midwest Conference on Mental Health Statistics held in Indianapolis, Ind., on October 1 and 2, 1958.

The most important aspect of this meeting was a discussion of research projects which the group may undertake on a cooperative interstate basis. Of major interest were factors affecting the admission of aged patients to State mental hospitals. A committee was appointed to design a research plan for such a study and this committee reported briefly on its progress at the conference. Research into the following problem areas was proposed:

1. Socioeconomic and demographic characteristics of the patients.
2. Reasons for admission to the State mental hospital.
3. Assessment of the type of care required by the patient at time of admission.
4. Assessment of the care provided during the course of the patient's hospital stay.
5. Background factors affecting admission.

Further committee work will be required before the design is completed.

Plans are being formulated by the 16 States in the area served by the Southern Regional Education Board to hold a meeting of statisticians in the mental hospital field. Seven of these States are now members of the Model Reporting Area, and it is the aim of this group to assist the remaining nine States in qualifying for membership.

Health Hazards in Drycleaning Plants

A study of drycleaning establishments to determine the extent of employees' exposure to solvents during cleaning operations has been conducted by the California Department of Public Health at the request of the State Board of Dry Cleaners.

State laws regulating drycleaning operations have been successful in promoting a safe working environment, but in some plants, as a result of poor operating procedure and gross negligence in maintenance, a high exposure to perchloroethylene solvent vapor has been observed during the study.

Plant operators favor the recommended use of an inexpensive halide-leak detector and testing for solvent leaks at frequent intervals.

*By Arthur S. Flemming, Secretary of Health,
Education, and Welfare, July 14, 1959*

Control of Radioactive Wastes

I AM HAPPY to report that the first Federal enforcement action to control contamination of interstate waterways by radioactive wastes has now reached a successful conclusion through voluntary agreement.

As a result, the Vanadium Corporation of America will take immediate steps to prevent radium from its uranium milling operations in Durango, Colo., from being discharged into the Animas River, which flows from Colorado into New Mexico.

Agreement was reached at the second session of a conference held under the auspices of the Public Health Service in Santa Fe, N. Mex., on June 24, 1959. The Surgeon General of the Public Health Service approved the agreement July 14, 1959, and will notify the water pollution control authorities of Colorado and New Mexico, who are responsible for enforcing it. The agreement provides that the Vanadium Corporation within 4 months will be employing measures to reduce the radium in its waste discharge to the minimum it is possible to achieve by known methods.

This first enforcement action involving radioactive pollutants in water is significant for several reasons:

1. It sets a precedent for maintaining high standards in the control of radioactive wastes and human radiation exposure.

Although by merely extracting solid particles of radium from the wastes discharged into the river, radioactivity would have been materially reduced, the agreement goes beyond this and includes removal of all radium that can be removed by known methods.

2. The value of the 1956 law authorizing the Public Health Service to undertake pollution

surveys of all interstate streams and to institute antipollution procedures has been dramatically demonstrated.

Approximately 30,000 persons in southwestern Colorado and northwestern New Mexico were using Animas River water, which ranged from 40 percent to 160 percent above maximum permissible levels of radioactive content. This fact was established by an intensive survey of the river, begun by the Public Health Service in April 1958 and completed in April 1959.

Because the law permits the Public Health Service to conduct water pollution surveys and hold conferences on the abatement of interstate pollution, the situation was brought under control before the population of the area had ingested sufficient amounts of this radioactive material to cause detectable health damage.

The pollution abatement procedure under the 1956 law is this: A conference is called by the Surgeon General. If agreement is not reached at the conference, or if the agreement concluded is not fulfilled, a public hearing is called by the Secretary of Health, Education, and Welfare. If the hearing board so recommends, the Secretary of Health, Education, and Welfare is empowered to issue a cease and desist notice which could lead to court action by the Attorney General of the United States.

During 1960, the Public Health Service expects to begin studies of the radioactive content of three rivers in Wyoming: Bighorn, Sweetwater, and North Platte.

3. The disclosure of a hitherto unsuspected hazard of chemical pollution was an important byproduct of the Animas River survey.

When the Public Health Service assigned an aquatic biologist to analyze the amount of radioactivity being absorbed by fish in the river—a standard procedure in such surveys—the biologist found that the river contained few fish and very little other aquatic life. Subsequent study revealed that a number of toxic

chemicals which were also contained in waste discharged by the Vanadium Corporation had caused this destruction.

Consequently, the company, in addition to controlling the radium in its wastes, will also recover the toxic chemicals before they reach the river.

Fluoride Naturally Present in Water Supplies

Fluoride occurs naturally in water used by communities in 43 States, according to a Public Health Service report "Natural Fluoride Content of Communal Water Supplies."

Based on data compiled by the dental directors of all State health agencies, the report indicates that the water supplies of 1,903 cities and towns with a combined population of 7 million contain enough fluoride naturally to prevent 2 out of 3 dental cavities.

In Texas, 2,700,000 persons in 356 towns use naturally fluoridated water. In New Mexico, 465,000 people, or 68 percent of the total population, live in communities with such water supplies.

More than 450,000 people in 136 Illinois towns and 406,000 in 184 Iowa communities drink water with fluoride present in nature. At least 100,000 people in each of 10 States, California, Colorado, Florida, Idaho, Indiana, Kansas, Louisiana, Michigan, Ohio, and Wisconsin, live in towns served by naturally fluoridated water supplies.

Thirty-five percent of the 7 million persons using naturally fluoridated water live in towns and cities with populations of more than 50,000. Thirty-eight percent live in towns of from 5,000 to 50,000 and 27 percent in communities of under 1,000.

The fluoride found naturally in water is identical in its effect to the fluoride used in controlled fluoridation, according to Dr. John W. Knutson, chief dental officer of the Public Health Service. The 1,800 cities now using controlled fluoridation adjust the fluoride content to that found in a great many of the naturally fluoridated water supplies throughout the country, or from 0.7 to 1.2 parts of fluoride per million parts of water. The 35 million people living in these 1,800 communities plus the 7 million using naturally fluoridated water means that 1 out of every 3 people using central water supplies now drinks water that has been fluoridated by nature or by the community.

A Record and Reporting System for Field Research Units

BENJAMIN E. CARROLL, M.A., and SAMUEL C. INGRAHAM II, M.D., M.P.H.

A UNIFORM system of records, files, and reporting has been devised to facilitate collection by several field research units of data suitable for consolidation. Its use permits efficient daily operation with the flexibility necessary to serve individual goals of each unit, yet makes practical the reporting of comparable data to a central office for reduction and processing.

The research, under the sponsorship of the Field Investigations and Demonstrations Branch of the National Cancer Institute, Public Health Service, deals with the cytology and epidemiology of human uterine cancer. Each of 10 field units aimed to examine initially around 50,000 to 75,000 or more women, recalling as many as possible for second and third examinations at yearly intervals. The total number examined by all the units is estimated to be of sufficient magnitude to provide statistically valid casefinding, prevalence, and incidence rates for invasive cancer and carcinoma in situ by age group.

In 3 years' operation the record and reporting system has proved effective and workable. A similar plan should be generally usable in medical and public health activities collecting uniform data from geographically separated field stations.

The field research projects obtain cytological specimens, identifying data, and selected medical history information from women recruited

from various segments of the population. The specimens are examined in the unit's cytology laboratory. The cytodiagnosis is entered on an individual patient record form for statistical analysis and is also reported to the examinee or her personal physician. Any necessary additional cytological, histodiagnostic, or clinical studies are performed by or at the request of the personal physician, and results of these are also entered on the examinee's record. Since the several units use similar cytological methods, the data can be collated and totaled.

Record Forms

Three principal records were designed for the study: a basic medical record card, an alphabetical index, and a recall card. The basic record card has undergone one redesign and revision to take care of practical problems encountered in operation.

The patient medical record is an 8-inch by 10-inch card with fairly generous space for each entry (fig. 1). Its format is intended to facilitate reduction of the data to punchcards. To simplify coding, most of the history items are multiple-choice questions that can be answered by a checkmark or a single word or number. Very little writing need be done to record the complete personal and medical history called for. Results of cytology slide readings and tissue diagnoses are described verbally in designated spaces, but they are also recorded by code numbers. Use of the diagnostic codes simplifies uniform reduction of data for all projects and obviates the interpretation of handwriting and medical terms by coding clerks. Space is provided for results of repeat tests as necessary.

Mr. Carroll is statistician in the Environmental Field Studies Section, and Dr. Ingraham is head of the Diagnostic Development Section, National Cancer Institute, Public Health Service, Bethesda, Md.

The classification of cytology results and final diagnoses based on tissue studies or other procedures was agreed upon by all project directors. To accommodate minor variations in the scheme, two-digit codes were devised. All directors agreed, however, to observe the dividing lines between the five major categories of results as uniformly as possible.

Both sides of the card are identical so that two series of tests may be recorded. Some projects, however, find it more practical to use a fresh card for each series. When used in the immediate environs of a project, this record is printed on a fairly heavy index stock, but when it must be folded or rolled for mailing, it is printed on a lighter stock.

The patient record is initiated by the physician, nurse, or technician who collects the speci-

men and enters and checks the identification and medical history items. Detailed instructions for completing the card were issued to the staff of all projects. The field unit's central office assigns case numbers for identification and as an automatic count of the number of women examined. An examinee retains the same case number throughout her participation in the project, and each number is used only once. If a number is vacated because of duplication, it is reassigned to a new patient. The field unit keeps a register of its case numbers, showing the numbers in serial order and the names of the examinees.

Patient record cards are filed by case number. This system has the major advantage of expandability by addition at the end. In an alphabetical file, when expansion becomes necessary,

nearly all cards in the file must be shifted. Also, numbers can be sorted and filed much more quickly and accurately than names.

For filing these 8-inch by 10-inch cards, cases are available with shallower drawers than are used in regular letter files. Thus, a case of standard height accommodates five drawers instead of four, which greatly reduces the space required for filing cabinets.

In order to attain the individual project goals, repeat examinations are necessary at stated intervals, usually yearly, on as many examinees as possible. A recall file has been set up to assist in this function. It operates as a tickler file to indicate which examinees are to be recalled each month. The recall card, 3 by 5 inches in size, contains name and case number of patient, home address and telephone, business address (if any), husband's name, and name and address of a friend or relative who presumably will always be in touch with her, plus screening and recall dates (fig. 2). Experience has shown that contact and recall is facilitated greatly by the supplementary information on this card. Quantitative evaluation of the usefulness of the various items in contacting examinees has not been attempted, but each item has been useful in locating some examinees.

Recall cards are filed according to month of

examination. A set of index guides for the months of the year is required, along with 12 sets of alphabetical guides, so that names may be alphabetized within each month. All cards filed under a given month are then ready to be lifted out and used for recall 1 year later. If a smear or other specimen is received for a patient before her recall date, her recall card is moved to the current month so that she will not be recalled until a year after the most recent examination.

The recall file is intended only for annual or other routine recalls. The medical record cards for examinees requiring repeat of unsatisfactory or suspicious tests or tissue studies are kept in a temporary file which can be accommodated easily without special provisions. The cards in this file for examinees who do not respond within a reasonable time (60 to 90 days) and who cannot be located by the followup staff are removed and placed in the main record files as incomplete cases. This procedure avoids obstructing the very active temporary file with cards that may never be reactivated.

Since the patient record cards are filed numerically, an alphabetical index is kept to enable the staff to find records by name of the examinee. The alphabetical index is made up on panels mounted on a rotary stand (fig. 3).

Each panel accommodates a large number of narrow strips of composition board on which are typed names, addresses, case numbers, and any other identifying information desired.

As the cytological specimen and the medical record card are received at the project records office and before a case number is assigned, each name is checked against the alphabetical index to determine whether or not the individual is a new participant. If an examinee has been seen previously, the existing card is pulled from the file and the new results added. The record cards for new patients are alphabetized and index strips are typed from the cards so that the strips are automatically in proper order for adding to the panels.

The alphabetical index may be started with a small capacity and later expanded. However, starting with the full expected capacity reduces the need for shifting panels and strips as the index expands. In our system, all project directors elected to start with the full capacity. Subdivisions separating an alphabetical file of names into any given number of approximately equal groups are available from filing equipment manufacturers. These are important, since the filling of panels at unequal rates will necessitate the shifting of large numbers of strips from panel to panel to make room. Alphabetical guides for labeling the panels may be purchased or prepared to correspond to such subdivisions.

In addition to these basic records, each project has established one or more subsidiary files for special purposes. These files usually consist of duplicates or abstracts of a portion of the main medical record file to keep closer track of "all positive cases" or "all suspicious cases," for example.

Reporting System

Several methods of reporting the data to the central office were considered. Accuracy and simplicity were of course basic requirements, but also it was considered essential to obtain copies of records with minimum disturbance of recordkeeping routines at the field units. Although a number of methods might have met these objectives, it was decided to transmit copies of the records by microfilm. Microfilm-

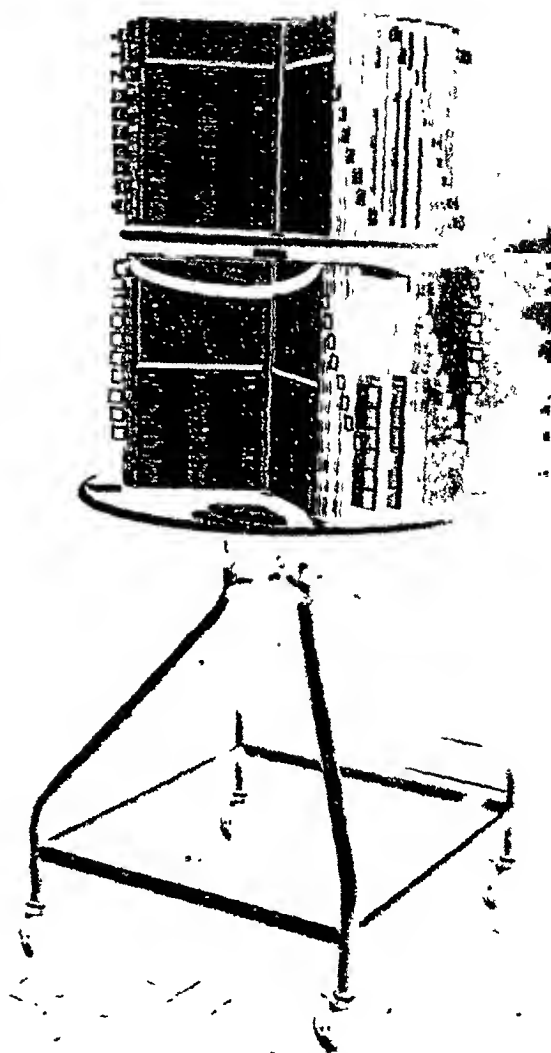

Figure 3. Alphabetical index

ing is a simple procedure, and it provides a batch of records that is a compact and inseparable unit rather than 1,800 separate prints.

A microfilmer for photographing records on 16-mm. film (at a reduction of 19 to 1) was placed in use in each project. The equipment is rented, and instruction and service as well as installation are included in the rental charge. Thus the personnel of the field unit have a minimum of responsibility for taking care of the machines.

A procedure was set up for filming each record as soon as it is completed and before it is permanently filed. After a record is filmed, the last entry is checkmarked. This notation

enables the central office coding clerks to tell which results are new if the same record is refilmed later to show more information. When an additional examination is entered on the same form, the record is refilmed to show the new information and the last line of results is again checkmarked. When an annual reexamination is made, the entire case record is filmed, in reverse chronological order, so that the coding clerks can evaluate the patient's entire record.

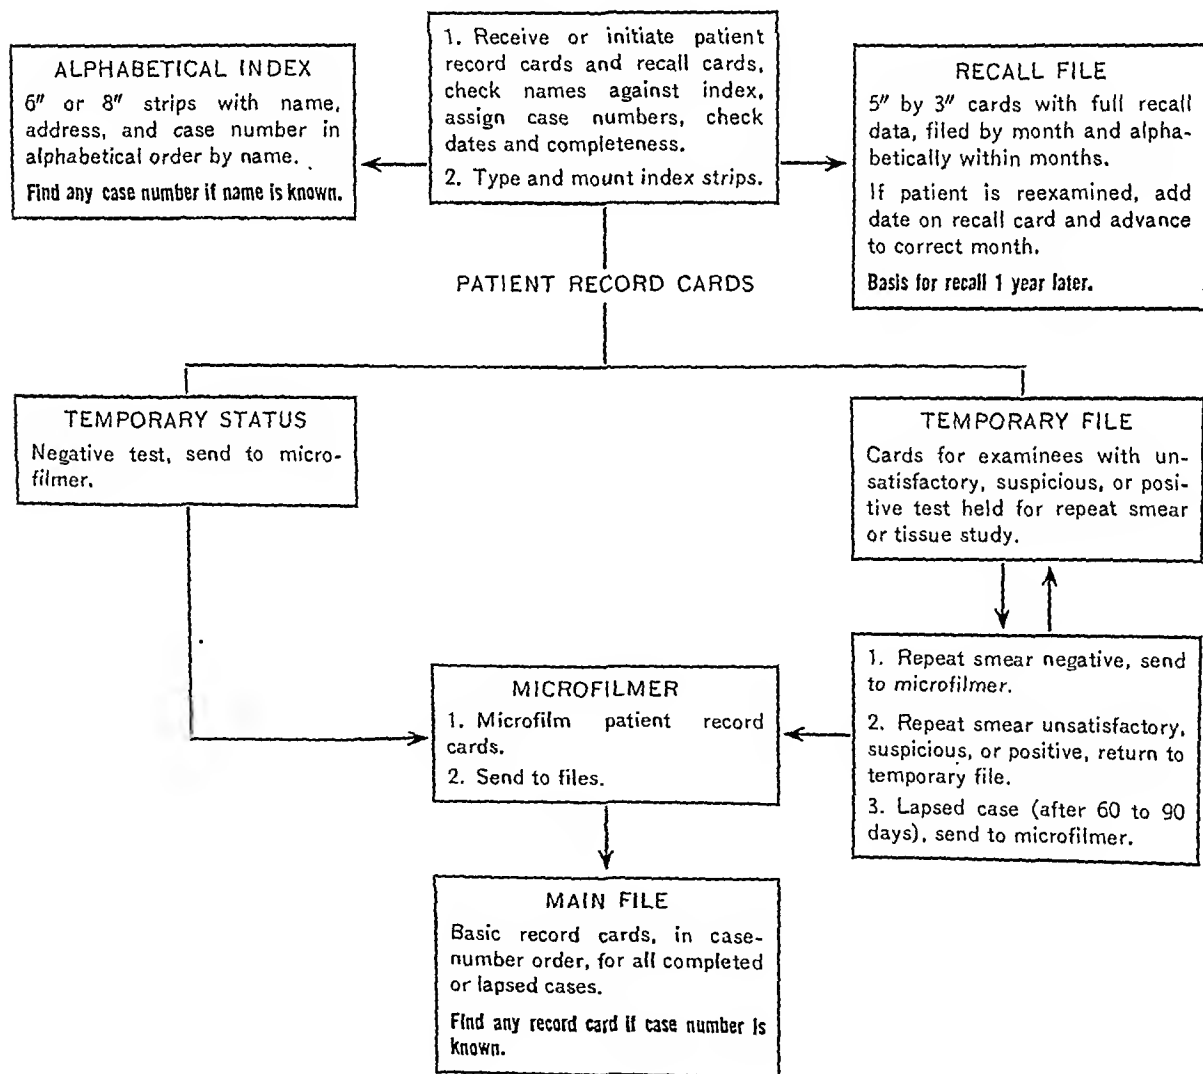

Since there is occasionally a faulty film, the field unit keeps a record of case numbers included on each reel or flags the group of cards

in the file until informed by the central office that the film has been received and is satisfactory.

The microfilm reels are mailed in preaddressed envelopes to the vendor in Washington, D.C., where they are developed and forwarded to the central office of the study. When a reel is received, the central office routinely mails a fresh reel of film to the field unit.

The microfilm method of transmitting records is highly satisfactory. It provides the central office with a current account of the number of examinees and the correctness of record-keeping. It makes possible the current or nearly

Flow Chart for Cytology Project Records

current reduction of all data to punchcards. It encourages accurate and legible records, since everyone concerned knows that the records must be capable of photographic reproduction. The method is economical for large numbers of records, and no copying errors can occur. Project files are not disturbed, since record cards are microfilmed before they are filed.

Central Office Operations

Centralization of coding operations has proved its worth. It permits control by the central office of the code used, the interpretation of coding rules, special decisions, and the like. The central office, having in mind the objectives of the entire study, can apply the same rules and procedures to all data.

For economy and speed, coding is done and cards are punched directly from the microfilm images. This procedure is used by the National Office of Vital Statistics, Public Health Service, for the large volume of documents it receives on microfilm. It has proved practical and economical, since the touching of a key is quicker and less laborious than writing a code digit. The coding clerk, after a few weeks' training, becomes thoroughly familiar with the code and quite adept at the job, coding and punching from 75 to 100 cards per hour. During the training period and early experience of a coder, all cards are verified by an experienced operator. Thereafter, only non-negative cases and 10 percent of the negatives are verified.

All non-negative cases are verified because, since they are a small percentage of all cases, any errors would have a great effect on results. A few errors in the negative cases, on the other hand, could have only a minor effect on the analysis. Furthermore, essential items on negative cards can be checked in batches by needle or sight, since certain punches must be the same in all cards.

Direct coding and punching has proved particularly useful in handling the unexpectedly large volume of repeat examinations. Copying or the use of carbon paper would have meant a tremendous amount of additional clerical work, with greater opportunity for errors and misunderstandings. With the system in use, a re-

peat examination calls merely for an additional filming of the card or cards, and an up-to-date punchcard can be produced quickly from the film. Duplicate cards are detected by mechanical matching of case numbers, and the up-to-date card is selected to be retained in the file.

The punchcards contain 45 columns of data which are uniform for all field units. Those units using different types of specimens and those collecting special data are assigned additional columns. Six columns are used for check or control punches beyond the actual data recorded. Four types of cytological smear are used by the 10 units, but the results of a given type of specimen are always punched in the same columns. For rapid routine tabulations, the cytology results are summarized in one column. The code for repeat examinations is shorter than for original examinations, since most of the medical history is already on record and need not be repunched. Items of data for successive examinations are always punched in the same columns to achieve uniformity in sorting and tabulating and in summarizing the cards for an examinee.

Summary

A system of uniform records and files is now in operation in a large research study of human uterine cancer. Designed for collection by a number of separated field stations of data that can be consolidated, it should be adaptable to the needs of other medical or public health projects with similar objectives.

The record system is coordinated with transmittal of data by microfilm to a central office. There the data are coded from the microfilm images and punched directly into cards. Centralization of coding has the advantage of uniformity, and prompt transmittal and punching of data give the further advantages of providing information on status of work and quality of records, making immediately available simple tabulations for administrative purposes and facilitating currency of punchcard data for preliminary or final analysis.

Copies of the instructions for filling out the basic record card, numbering of cases, and microfilming the basic record may be obtained from Mr. Carroll.

Epidemiology of DOG BITES

HENRY M. PARRISH, M.D., Dr.P.H., FRANK B. CLACK, V.M.D., M.P.H.,

DUANE BROBST, D.V.M., M.P.H., and JAMES F. MOCK, V.M.D.

Human and Environmental Factors

A RECENT survey of animal bites in selected areas of the United States showed a "reported" animal bite rate of 362 per 100,000 human population per year (1). In the same study it was estimated that about 611,500 persons were bitten by animals in the United States

Dr. Parrish is assistant professor of preventive medicine, University of Vermont College of Medicine, Burlington. Dr. Clack, the senior author of "Characteristics of Biting Dogs," the second section of this paper, is chief public health veterinarian, and Dr. Mock, public health veterinarian, of the Allegheny County Health Department, Pittsburgh, Pa. Dr. Brobst is a research assistant in the department of veterinary science, University of Wisconsin, Madison.

during 1957. Domestic animal losses cost about \$1 million per year, and medical and public health expenses cost about \$5 million per year (2). Dogs bite people more often than do any other domestic animals in this country, and they are the most common source of human rabies (3). Although dog bites occur frequently, produce human injury, pain, and anxiety, and are costly, as yet there has been no detailed epidemiological study of this problem. Epidemiology has demonstrated its value in acquiring the necessary facts to control infectious diseases and recently has been used successfully to study noninfectious and chronic diseases (4,5) as well as other kinds of animal bites (6). In this study we have tried to elicit the various human, dog, and environmental

factors associated with dog bites, and to determine if these factors indicate ways to prevent and control dog bites.

Materials and Methods

All dog bites reported during July and August 1958, in Pittsburgh, Pa., were studied in detail. This period was selected because dog bites are most prevalent during these summer months. Special dog bite report forms were mailed to the hospitals within the city limits and to physicians (general practitioners, internists, surgeons, and pediatricians) who might be expected to treat dog bite cases in their offices. Practicing veterinarians, personnel working in animal hospitals, members of the Animal Rescue League, and the police were also asked to report dog bites.

The report forms contained detailed questions about each dog bite accident. The information on the victim included name, address, age, sex, race, occupation, if he had been bitten during the past 5 years, and if he knew that the dog had bitten other people. Other data included the kind of animal inflicting the bite (hospitals were asked to report all animal bites), the hour (a.m. or p.m.), date, geographic place, anatomic location, and circumstances under which the bite took place, length and depth of the wound, number of sutures that would have been required if the wound had resulted from ordinary trauma, a checklist of items used in treatment, and the name and address of the animal's owner.

When the dog inflicting the bite was traced, its owner was asked to supply additional information to identify the factors associating the animal with the dog bite accident. These factors are described on pages 898-903.

Incidence

During the 2-month period, 947 dog bites were reported in Pittsburgh, 507 during July and 440 during August 1958, a bimonthly incidence of 14 dog bites per 10,000 human population. The annual incidence of dog bites in Pittsburgh is of about the same magnitude as that reported for other cities of comparable size in this country (1). It was felt that most of the treated dog bites in the city were reported: in 1957 only 230 bites were reported to have

occurred during July and 204 during August. Apparently the reporting system was more effective during July and August 1958 than during the same period in 1957. This improvement can be attributed to private physicians reporting dog bite victims whom they treated in their offices. Of course, some dog bite victims do not seek medical treatment. This seems particularly true if a dog bites his owner!

Characteristics of Victims

Sex. The bimonthly incidence of dog bites per 10,000 population was 19.46 for males and 8.84 for females. Therefore, males were the victims of dog bite accidents more than twice as frequently as females. This finding is consistent with the observation that males are more frequently involved in most types of accidents than females (7). This striking sex difference in the incidence of dog bites becomes apparent before the victims reach 5 years of age. Perhaps the high incidence of dog bites among males results from their more aggressive behavior and the fact that males are more likely to have dogs as pets. Generally, females prefer cats or other small animals as pets. Males had higher rates of dog bites in practically every age group (table 1).

Age. The victim's age was an important variable in dog bites. Eighteen percent of all victims were less than 5 years of age, 31 percent of the victims were 5 to 9 years old, and 27 percent were 10 to 19 years of age. Thus, 76 percent of all the victims were less than 20 years of age. For the most part this group consisted of preschool and school children. The rate of dog bites per 10,000 population provides a more meaningful measure of high-risk groups by age. School boys and girls aged 5 to 9 years have the highest bite rate (table 1). The second highest bite rate for males was found in the age group 10 to 19 years, whereas the second highest rate among females was in the less-than-5-year-old group. Children and youths less than 20 years of age have the highest rate because they are intimately associated with dogs as pets, they are often abusive to pets, and, in many instances, they do not know how to care for pets properly. In addition, persons less than 20 years of age are more likely to be engaged in

¹ Based on the 1950 U.S. census of the population of Pittsburgh, Pa.

activities which excite dogs, such as playing ball, running, riding bicycles, and delivering newspapers.

Race. There were 540 white males and 99 nonwhite males and 263 white females and 45 nonwhite females bitten by dogs. Although there were more bites among whites than nonwhites, the incidence of bites per 10,000 population at risk was higher for the nonwhites. The nonwhite population of Pittsburgh is not large and is composed primarily of Negroes. The rates of bites per 10,000 population was 18.75 for white males compared with 24.48 for nonwhite males, and 8.60 for white females compared with 10.58 for nonwhite females. There were no significant differences between the bite rates of the whites and the nonwhites, for both sexes, up to the age of 20 years.

From 20 through 49 years of age the nonwhites had a high rate of dog bites. This finding was associated with the occupations of the victims. Most of the nonwhite victims in this age range were employed in occupations which brought them to the dog owner's home in their jobs as delivery men, mailmen, milkmen, laborers, and garbage collectors. There was no evidence to suggest that nonwhites were more likely to report dog bites than whites, nor that dogs were more partial to biting nonwhite than white persons. The higher rate of dog bites among Negroes in Pittsburgh is in agreement with data obtained from a survey of dog bites in Arlington, Va. (8).

Occupation. Definite groups of individuals run a high risk of being bitten by dogs. School children and preschool children were the most frequent victims, especially if they either owned a dog or lived within three houses of a dog owner's home (table 2). Persons coming to the dog owner's home in the line of work also were frequently bitten. If newspaper boys and mailmen were included in this group, then 13 percent of all the victims were in this occupational category. During July and August 1958, 33 newspaper boys and 26

factors associated with dog bites, and to determine if these factors indicate ways to prevent and control dog bites.

Materials and Methods

All dog bites reported during July and August 1958, in Pittsburgh, Pa., were studied in detail. This period was selected because dog bites are most prevalent during these summer months. Special dog bite report forms were mailed to the hospitals within the city limits and to physicians (general practitioners, internists, surgeons, and pediatricians) who might be expected to treat dog bite cases in their offices. Practicing veterinarians, personnel working in animal hospitals, members of the Animal Rescue League, and the police were also asked to report dog bites.

The report forms contained detailed questions about each dog bite accident. The information on the victim included name, address, age, sex, race, occupation, if he had been bitten during the past 5 years, and if he knew that the dog had bitten other people. Other data included the kind of animal inflicting the bite (hospitals were asked to report all animal bites), the hour (a.m. or p.m.), date, geographic place, anatomic location, and circumstances under which the bite took place, length and depth of the wound, number of sutures that would have been required if the wound had resulted from ordinary trauma, a checklist of items used in treatment, and the name and address of the animal's owner.

When the dog inflicting the bite was traced, its owner was asked to supply additional information to identify the factors associating the animal with the dog bite accident. These factors are described on pages 898-903.

Incidence

During the 2-month period, 947 dog bites were reported in Pittsburgh, 507 during July and 440 during August 1958, a bimonthly incidence of 14 dog bites per 10,000 human population. The annual incidence of dog bites in Pittsburgh is of about the same magnitude as that reported for other cities of comparable size in this country (1). It was felt that most of the treated dog bites in the city were reported: in 1957 only 230 bites were reported to have

occurred during July and 204 during August. Apparently the reporting system was more effective during July and August 1958 than during the same period in 1957. This improvement can be attributed to private physicians reporting dog bite victims whom they treated in their offices. Of course, some dog bite victims do not seek medical treatment. This, seems particularly true if a dog bites his owner!

Characteristics of Victims

Sex. The bimonthly incidence of dog bites per 10,000 population was 19.46 for males and 8.84 for females. Therefore, males were the victims of dog bite accidents more than twice as frequently as females. This finding is consistent with the observation that males are more frequently involved in most types of accidents than females (7). This striking sex difference in the incidence of dog bites becomes apparent before the victims reach 5 years of age. Perhaps the high incidence of dog bites among males results from their more aggressive behavior and the fact that males are more likely to have dogs as pets. Generally, females prefer cats or other small animals as pets. Males had higher rates of dog bites in practically every age group (table 1).

Age. The victim's age was an important variable in dog bites. Eighteen percent of all victims were less than 5 years of age, 31 percent of the victims were 5 to 9 years old, and 27 percent were 10 to 19 years of age. Thus, 76 percent of all the victims were less than 20 years of age. For the most part this group consisted of preschool and school children. The rate of dog bites per 10,000 population provides a more meaningful measure of high-risk groups by age. School boys and girls aged 5 to 9 years have the highest bite rate (table 1). The second highest bite rate for males was found in the age group 10 to 19 years, whereas the second highest rate among females was in the less-than-5-year-old group. Children and youths less than 20 years of age have the highest rate because they are intimately associated with dogs as pets, they are often abusive to pets, and, in many instances, they do not know how to care for pets properly. In addition, persons less than 20 years of age are more likely to be engaged in

probably somewhat less than 10 percent of all dog bites produce moderately severe and severe injuries.

Few human fatalities result from dog bites. During 1955 there were only 10 human deaths in the United States from dog bites (1). It is of interest that the percentages of moderately severe and severe injuries according to the anatomic sites were head, face, and neck, 26 percent; upper extremities, 11 percent; and lower extremities, 4 percent. This phenomenon seems indirectly related to the amount of protective clothing worn over these parts of the body.

The head, face, and neck are usually uncovered, while shoes, socks, skirts, and trousers afford some protection to the lower extremities. In this study, only 2 of the moderately severe and severe dog bite wounds on the extremities required subsequent plastic surgery, while 13 of those on the head, face, and neck did. Other studies are in agreement that a high proportion of dog bite wounds requiring surgical and plastic surgical procedures are on the head, face, and neck (9, 10).

Mechanism of bite accidents. One of the most interesting aspects of dog bites is the manner in which they occurred. A recent study of mammalian bites among young children indicated that often the child—and not the animal—provoked the bite (11). To elicit the causes, the victim's account of the circumstances of the bite was compared with the dog owner's account of how the bite happened. It was felt that the owner's views might present the dog's side of the story. The dog owners were eager to cooperate in this study, expressed sympathetic concern for the victims, and, with two exceptions, displayed no hostility. About one-third (32 percent) of the owners stated that they witnessed the dog bite accident, and an additional 13 percent of the dog bite accidents were seen by another member of the family or by a neighbor. Therefore, about one-half of the dog bite accidents were witnessed by a person other than the victim.

The mechanisms of bite accidents fall into four major categories: (a) bites unprovoked by humans; (b) bites incurred while petting or playing with dogs; (c) bites precipitated by human activities; and (d) all others (table 4). In only 9 percent of the bites did the dog own-

ers disagree with the victim about how the bite happened. Approximately 4 percent of bites unprovoked by man and 5 percent of the bites incurred while petting or playing with dogs were attributed by the owners to abusing and teasing the dog or to trespassing. Taking these differences into account, it seems reasonable to state that about one-third of the bite accidents resulted from dogs biting maliciously without human provocation; one-third, while the victims were petting or playing with dogs; and one-third, when human activities provoked the dogs to bite.

Environmental Factors

There is a definite biological pattern for dog bites just as there is a comparable pattern for

mailmen were bitten by dogs in Pittsburgh. Projection of these findings to a national level indicates that probably tens of thousands of newspaper boys and postmen are bitten by dogs in this country annually. Veterinarians and their assistants also would appear to be frequent victims of dog bites. For example, of the six veterinarians bitten during this 2-month period, five, or 83 percent, stated that they had suffered previous dog bites during the past 5 years.

The percentages of individuals in the various occupational groups who experienced previous dog bites in the past 5 years were mailmen, 11; preschool children, 9; school children, 6; newspaper boys, 6; housewives, 4; and persons coming to the house in the line of work, 4. These findings further demonstrate the frequency of dog bites in these occupational groups. Measures to prevent and control dog bites should be directed toward these high-risk occupational groups.

Anatomic part bitten. As one might suppose, most dog bites (76 percent) were inflicted on the extremities, 39 percent on the legs and 37 percent on the arms. This anatomic distribution of bites is consistent with the height of dogs in relation to man, with the fact that people use their arms and legs to ward off attacking dogs, and with the observation that the extremities provide a better biting surface for dogs than the trunk.

It is shocking that 151, or 16 percent, of the dog bites occurred on the victim's head, face, and neck. With four exceptions, all of these potentially disfiguring bites about the head, face, and neck occurred among children less than 12 years of age. In a community survey of dog bites in Arlington, Va., 17.8 percent of the bites were located on the head and neck of the patients (8). One investigator reported that 25 percent of all dog bites treated in a general hospital were on the head and neck of the victims (9). Only 33, or 4 percent, of the 947 dog bites were on the buttocks and lower back.

Severity of wounds. Prior to this study, little was known about the severity of the wounds resulting from dog bites. The concept of a biological gradient was used for classifying the severity of dog bites. At the two extremes of

the gradient are dog bites which produce no detectable injury and those which result directly or indirectly in the death of the individual. Wounds were classified according to severity as (a) none—dog bites producing no detectable injury; (b) minor—dog bites producing abrasions, lacerations, contusions, and puncture wounds which would not have required sutures if the wound had been produced by ordinary trauma (not an animal bite); (c) moderate—wounds which would have required from 1 to 10 sutures if they had resulted from trauma; and (d) severe—wounds which would have required more than 10 sutures if they had resulted from trauma.

Of the 947 reported dog bites, 20, or 2 percent, produced no detectable injury; 831, or 88 percent, resulted in minor injuries; 86, or 9 percent, were moderate injuries; and only 10, or 1 percent, were severe injuries (table 3). There were no fatal injuries. Dog bites which result in no detectable injury probably occur in greater numbers than indicated in this study because these patients do not often seek medical treatment. Also, it seems likely that many persons with minor injuries resulting from dog bites fail to seek medical treatment. Therefore,

Table 3. Anatomic location and severity of dog bite wounds of victims, Pittsburgh, Pa., July and August 1958

Location of wound	Severity of wounds ¹				Total	
	None	Minor	Moderate	Severe	Number	Percent

ported by clinical impressions of epidemics of dog bites during the summer months and by popular notions of dog days. There is reason to believe that this seasonal variation of dog bites is nationwide; however, it is probably not as distinct in the southern parts of the country. The high incidence of bites during the summer months more likely resulted from more children being "exposed" to dogs at this time. Also, in colder climates dogs are allowed more freedom during summer months.

During the winter (school) months most dog bites occurred on Saturday and Sunday (1). However, during the summer months there was little variation in the frequency of bites by days of the week (table 6). Of 947 reported bites, 141, or 15 percent, happened from 6 to 11:59 a.m.; 361, or 38 percent, from 12 to 5:59 p.m.; 388, or 41 percent, from 6 to 11:59 p.m.; and 24, or 3 percent, from 12 to 5:59 a.m. The time was unknown for 33, or 3 percent, of the bites. Of course, not many dog bites would be expected from 12 to 5:59 a.m., but it is difficult to explain why only 15 percent of the bites occurred from 6 to 11:59 a.m. Most dog bites (79 percent) happened between noon and midnight.

Discussion

This study of the epidemiology of dog bites would seem to indicate that human factors are more important than environmental factors in the genesis of dog bites. Most environmental factors associated with dog bites reflect man's activity at a particular place or time rather than specific effects of environment per se.

However, the geographic distribution of bites by city wards points out areas where intensive control measures should be carried out.

On the basis of human factors which were unveiled in this study, certain recommendations for the prevention of dog bites can be made:

- Do not give a dog to children under the age of 6 years. This might help eliminate about 18 percent of the bites.
- Teach children how to care for their pets and not to abuse or tease dogs.
- Discourage playing ball with a dog, riding bicycles and other vehicles in the vicinity of excited dogs, and running while playing with a dog, if it excites him. These measures might prevent about 10 percent of all dog bites.
- Do not pet, startle, or take food away from a dog while feeding him and do not intercede in dog fights. These suggestions might eliminate another 10 percent of the bites.
- Exercise caution while assisting injured and sick animals, avoid abruptly arousing sleeping dogs, and be careful in picking up pups so as not to offend the mother dog. These measures might prevent another 3 percent of all bites.

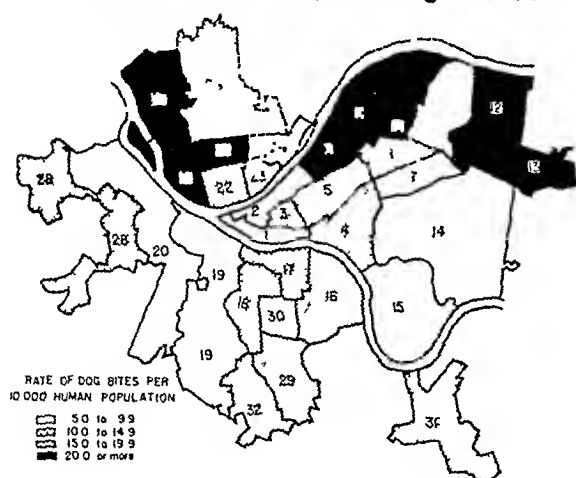

- Avoid holding your face next to a dog's to prevent disfiguring facial wounds.

Admittedly, these preventive measures are confining for dog owners, but they are suggested on the basis of scientific facts, and if they were followed, about 40 to 50 percent of all dog bites might be prevented.

Summary

An epidemiological study was made of 947 dog bite accidents which occurred in Pitts-

**Geographic distribution of dog bites by wards
in Pittsburgh, Pa., July and August 1958**

other types of animal bites (6, 12). Some of the environmental conditions investigated in this study were the geographic distribution of bites by city wards, the relation between bites and proximity to the dog owner's home or the victim's home, the seasonal variation of bites, and the frequency of bites according to days of the week and hours of the day.

Geographic location. To test the hypothesis that dog bites occur more frequently in residential areas than in business and industrial areas of the city, the incidence of dog bites by city wards was calculated by tracing the address where the bite was reported to have happened.

Estimates of the 1957 population rather than the 1950 census, which does not reflect recent population movement within the city, were used to calculate the incidence of dog bites per 10,000 human population for the 32 wards of Pittsburgh during the study period (see chart).

Wards 1 and 2 are downtown business areas of Pittsburgh which had less than 10 bites per 10,000 population. The wards with the highest rates of bites (6, 9, 10, 12, 13, 21, 25, and 27) are primarily residential; industrial areas (17, 19, and 20) had relatively low rates. Some of the differences in rates among wards may be due to differences in dog populations. Poor reporting in some wards was not thought to be a major bias influencing the incidence of bites.

These findings reflect the fact that dog bite accidents are most prevalent in areas where homes are most abundant, and children, the

most frequent victims, and dogs are more common.

The report forms also indicated that most bite accidents happened in the vicinity of the dog owner's residence rather than the victim's (table 5). Vicinity included inside the home, the yard, and the street in front and back of the home; neighborhood was the area within 2 blocks' radius of the home. In the study, 65 percent of the accidents occurred in the vicinity of the dog owner's home, 18 percent in the neighborhood near the dog owner's home, and 9 percent in the vicinity of the victim's home. Most of the dogs responsible for bites which occurred away from the neighborhood of the dog owner's home and the victim's home were difficult to trace. Presumably, a large proportion of these animals were stray dogs.

Seasonal variation. In a previous publication (1) we demonstrated a seasonal distribution for dog bite accidents in Pittsburgh. The incidence of bites was lowest during the winter months, increased during March and April, and reached a peak during the summer months. A similar seasonal distribution of dog bites was reported for Arlington, Va. (8), and for Ann Arbor, Mich. (9). These observations are sup-

¹ Area within 2 blocks' radius of home.

large proportion of the dogs which could not be traced were strays. Of those traced to owners, 571, or 74 percent, were licensed, and 196, or 26 percent, were not. This study was concerned primarily with the 571 dogs which were traced to owners and had dog licenses, but many of the findings apply to the unlicensed dogs with owners.

Sex. Of the licensed dogs inflicting bites, 416 were males and only 155 were females (table 1). If the licensed dog population at risk were unknown, it would be easy to assume that males are more likely to bite people than females. This was not true. Licensed female dogs had a bite rate of 4.1 per 100 dogs, whereas males had a bite rate of only 2.7 per 100 dogs. Contrary to popular opinion, this sex difference in bite rates was not related to the females caring for newborn pups as only 11, or 7 percent, of the 155 bites happened while the victim was playing with a pup. Only one bite by a female dog was reported to have occurred while the dog was in its oestrous cycle. Apparently city dwellers prefer owning male dogs, since 15,579 licenses were issued for male dogs and only 3,755 for female dogs. There is no evidence to suggest that a dog owner is more likely to obtain a license for a male dog.

Age. Dogs less than 6 months of age do not require a license in Pittsburgh. It is interesting that more than 50 percent of the licensed dogs were less than 5 years old (table

1). A vast majority (80 to 85 percent) of the licensed dogs of both sexes were from 1 to 9 years of age, and only about 10 percent were 10 years of age or over. A striking finding is that younger dogs are more likely to bite people than older dogs. This was particularly true for dogs between 6 and 11 months of age. A smaller proportion of dogs 5 years of age or over bite humans than would be expected. Perhaps younger dogs experience difficulty in adjusting to their domestic status. In effect, they have not been trained how to behave toward people. Young dogs in intimate association with young children would seem to invite frequent dog bite accidents.

Breeds. One of the most important hypotheses tested is that certain breeds of dogs are more likely to bite people than other breeds. Veterinarians from time to time have expressed clinical impressions about the temperament of certain breeds of dogs, but, as far as we know, there have been no previous studies to confirm these impressions in relation to dog bites.

The recognized breeds of dogs were arranged into six groups, a modification of the American Kennel Club classification (13). Mixed breeds and unrecognized breeds were listed as additional groups. Grouping the many breeds of dogs in these large categories was the only practical way to handle the data, and thousands of dog bite cases would have been required to demonstrate significant differences in

² Licenses not required for dogs

burgh, Pa., during July and August 1958. The incidence of bites per 10,000 human population was 19.46 for males and 8.84 for females; 76 percent of the victims were less than 20 years of age. The rate of bites was higher for non-whites than for whites.

High-risk groups identified were: school children, preschool children, persons coming to the dog owner's house in the line of work, newspaper boys, mailmen, and veterinarians.

Seventy-six percent of the bites were inflicted on the extremities, 16 percent on the head, face, and neck, and 8 percent on the trunk. Only about 10 percent of the bites were moderately severe or severe. There were no fatal dog bites. A high percentage of facial wounds required subsequent plastic surgery.

About one-third of the bite accidents resulted from dogs biting maliciously without human provocation, one-third happened while the victims were petting or playing with dogs, and one-third were attributed to human activities which caused the dogs to bite.

The following environmental factors were identified: the incidence of bites was higher in residential than in business or industrial areas of the city; 65 percent of the bites happened near the dog owner's home, 18 percent in the neighborhood near the owner's home, 9 percent near the victim's home, and the remaining 8 percent occurred elsewhere in the city; most dog bites happened during the spring and summer months; and 79 percent of the bite accidents occurred between noon and midnight.

Characteristics of Biting Dogs

PRACTICALLY NOTHING is known about the characteristics of dogs which bite man. The question of how the dogs involved in dog bite accidents differ from other dogs is as important to the veterinary epidemiologist studying dog bites as determining the classification, type, and strain of a bacterial agent is to a microbiologist.

In an epidemiological study of 947 dog bite accidents which occurred during July and August 1958 in Pittsburgh, Pa., we tried to determine what breeds of dogs are most likely to bite people, to elicit other characteristics, such as age and sex, of the dogs associated with accidents, and to find the pertinent animal factors which are necessary for planning an adequate dog bite and rabies control program.

In this study the name and address of the owner of the dog were obtained from the dog bite report forms sent in by hospitals and physicians treating bites. When this information was not available from the report form, the Allegheny County Health Department and the Pittsburgh Police Department traced the dog owners. They were requested to complete a questionnaire supplying the following information: the name and address of the owner;

the age, sex, and breed of the dog; number of times the dog had bitten other people within the past year; vaccination against rabies and date; possession of a 1958 dog license and the number of the license; involvement in frequent dog fights; the circumstances of the bite accident as the owner understood it; and whether the owner witnessed the bite accident.

One serious limitation to all dog population estimates is the unknown number of stray dogs. This statistical problem was circumvented by limiting the study to licensed dogs.

According to the records of the Pittsburgh Dog Licensing Bureau, 19,334 dog licenses were issued as of September 1, 1958, 15,579 for male dogs and 3,755 for female dogs. The rates of bites inflicted by licensed dogs were computed using 19,334 as the population base. Information about the age, sex, and breed was obtained by studying a 2 percent random sample of the total licensed dog population.

Incidence

Of the 947 dogs inflicting bites, 767, or 81 percent, were traced to owners, and 180, or 19 percent, could not be traced. Presumably, a

large proportion of the dogs which could not be traced were strays. Of those traced to owners, 571, or 74 percent, were licensed, and 196, or 26 percent, were not. This study was concerned primarily with the 571 dogs which were traced to owners and had dog licenses, but many of the findings apply to the unlicensed dogs with owners.

Sex. Of the licensed dogs inflicting bites, 416 were males and only 155 were females (table 1). If the licensed dog population at risk were unknown, it would be easy to assume that males are more likely to bite people than females. This was not true. Licensed female dogs had a bite rate of 4.1 per 100 dogs, whereas males had a bite rate of only 2.7 per 100 dogs. Contrary to popular opinion, this sex difference in bite rates was not related to the females caring for newborn pups as only 11, or 7 percent, of the 155 bites happened while the victim was playing with a pup. Only one bite by a female dog was reported to have occurred while the dog was in its oestrous cycle. Apparently city dwellers prefer owning male dogs, since 15,579 licenses were issued for male dogs and only 3,755 for female dogs. There is no evidence to suggest that a dog owner is more likely to obtain a license for a male dog.

Age. Dogs less than 6 months of age do not require a license in Pittsburgh. It is interesting that more than 50 percent of the licensed dogs were less than 5 years old (table

1). A vast majority (80 to 85 percent) of the licensed dogs of both sexes were from 1 to 9 years of age, and only about 10 percent were 10 years of age or over. A striking finding is that younger dogs are more likely to bite people than older dogs. This was particularly true for dogs between 6 and 11 months of age. A smaller proportion of dogs 5 years of age or over bite humans than would be expected. Perhaps younger dogs experience difficulty in adjusting to their domestic status. In effect, they have not been trained how to behave toward people. Young dogs in intimate association with young children would seem to invite frequent dog bite accidents.

Breeds. One of the most important hypotheses tested is that certain breeds of dogs are more likely to bite people than other breeds. Veterinarians from time to time have expressed clinical impressions about the temperament of certain breeds of dogs, but, as far as we know, there have been no previous studies to confirm these impressions in relation to dog bites.

The recognized breeds of dogs were arranged into six groups, a modification of the American Kennel Club classification (13). Mixed breeds and unrecognized breeds were listed as additional groups. Grouping the many breeds of dogs in these large categories was the only practical way to handle the data, and thousands of dog bite cases would have been required to demonstrate significant differences in

bites among the individual breeds. Owing to the larger number of breeds in each group, the following levels of confidence were set: probably significant when $P = < 0.05$; significant when $P = < 0.01$; highly significant when $P = < 0.001$.

Most people in Pittsburgh own dogs of mixed breeds (table 2). Hounds, terriers, and sporting dogs ranked next in popularity. The large number of mixed breeds with licenses would seem to suggest that people obtain licenses for these dogs about as often as they do for dogs of recognized breeds. The data in table 2 indicate that working dogs are much more likely to bite people than any other group. The working dog group includes the following well-known breeds: boxers, collies, Eskimo dogs, German shepherd dogs, great Danes, Saint Bernards, and Doberman pinschers. For this group 48 bites were expected, but 90 were reported, indicating a highly significant difference.

Sporting dogs inflicted more bites than were expected (59 expected, 75 reported). This difference is probably significant ($P = < 0.05$). The sporting dog group includes various breeds of pointers, setters, retrievers, and spaniels. On the other hand, hounds bite fewer people than would be expected (82 expected, but only 34 reported). These findings indicate that hounds are relatively safe dogs to own. No significant differences in the frequency of bites could be demonstrated for mixed breeds, terriers, toys, nonsporting dogs, and unrecognized

breeds. It was not possible to single out an individual breed as being particularly vicious. This preliminary study, however, suggests that such breeds probably do exist and that additional studies along this line of inquiry may prove fruitful.

Behavior. To determine whether a pet was a chronic offender, a history of the previous biting experience of dogs involved in bite accidents was sought from owners. Victims were also asked about the animal's history because owners can be unaware that their pets have inflicted a bite, and a victim may know of others bitten by the same dog.

The dog owners volunteered the following information about the number of bites their dogs had inflicted during the past year. Forty-seven dogs inflicted 2 bites; 16 dogs inflicted 3 bites; 1 dog, 4 bites; and 4 dogs, 5 bites. Most of the dog owners expressed considerable concern about what to do with dogs that were chronic biters. On the other hand, the victims stated the dog which bit them had bitten the following number of persons (including the victim) in the last year: 83 dogs bit 2 people; 2 dogs bit 3 people; and 1 dog bit 8 people. Fifteen percent of the dog owners did not agree with the victims' statements. However, it was apparent that some dogs are notorious for biting people.

Only 15 of the owners stated that their dogs were involved frequently in dog fights. If these impressions of dogs' pugnacious behavior toward other dogs are correct, then there is no

Table 2. Distribution of bites inflicted by various groups of licensed dogs, Pittsburgh, Pa., July and August 1958

relationship between dogs' behavior toward other dogs and their behavior toward people.

As mentioned previously in this study, approximately one-third of the bite accidents resulted from dogs biting maliciously without human provocation, one-third were incurred while the victims were playing with or petting dogs, and one-third resulted from human activities which goaded dogs to bite. These findings would seem to suggest that an interaction of overt behavior on the part of people and dogs figures in most (probably well over two-thirds) of the bite accidents.

Licenses and Immunity

Only 767 dogs, or 81 percent, could be traced to owners. The remaining 180, or 19 percent, either were strays or could not be traced. This finding would seem to indicate that Pittsburgh has a relatively large stray dog population. Only 74 percent of the dogs which could be traced to owners had dog licenses. A more active campaign of dog licensing and dog catching is needed to control the stray and unlicensed dogs.

Only 264, or 34 percent, of the animals traced¹ to owners had been vaccinated against rabies. Of these, 57, or 22 percent, had not been given booster injections within the past 3 years. Most dogs (468 or 61 percent) had not been vaccinated against rabies, and 35, or 5 percent, of the owners did not know the status of their dog's immunity. As one might expect, a higher proportion of dogs with licenses had been vaccinated than dogs without licenses. Probably a high proportion of the 180 dogs which could not be traced have not been vaccinated.

Improved vaccines are available for active immunization (14,15). Adequate control measures plus mass rabies vaccination of the canine population has been shown an effective means of eliminating canine rabies from a community (16). Although no human rabies and only one case of animal rabies have been reported in Pittsburgh or Allegheny County during the past 3 years, numerous cases have been reported from adjacent counties. At the present time, the canine population of Pittsburgh is largely susceptible to rabies and the soil is ripe for a rabies epidemic. On the basis of these findings,

a mass rabies immunization program is indicated, and legislation is needed to make rabies immunization a requirement for dog licensure. These recommendations are in accordance with those of the Expert Committee on Rabies of the World Health Organization (17).

Discussion

A study of the epidemiology of dog bites in the United States would seem important for the following reasons: between 600,000 and 1 million people are bitten by dogs every year (1); about 10 percent of all dog bites produce serious injuries although few result directly in human deaths; dogs are the primary source of human exposure to rabies; although only 10 to 20 people die of rabies in this country every year, about 50,000 individuals receive antirabies treatment (18); other diseases are transmissible from dogs to man through dog bites; and an immeasurable amount of anxiety and fear is experienced by parents when their child is bitten by a dog. On the other hand, dogs will probably continue to provide people with much pleasure and companionship. It seems reasonable to believe that many dog bites can be prevented when the facts about how they take place are known.

Inferences about the age, sex, and breed of the dogs were made by comparing the licensed dogs which bit people with the total licensed dog population of Pittsburgh (19,334 dogs). However, among the dogs which were traced there were no significant differences in the age, sex, and breed distributions of the 196 unlicensed dogs compared with the 571 licensed dogs. Therefore, there is reason to believe that the findings in this study may pertain to 767, or 81 percent, of the dogs which bit people. This observation would seem to increase the reliability of the data and support the validity of the findings. Poor reporting did not seem to be a major source of error, as it was felt that most dog bite accidents were reported. Biases in reporting a number of the items were corrected by comparing the victim's statements with the owner's statements. There was a surprisingly high degree of agreement in most instances.

Dog factors would seem to rank along with

human factors in the ecology of dog bites. Environmental factors occupied a relatively minor role. Female dogs inflicted a higher rate of bites per 100 (4.1) than male dogs (2.7). This difference could not be attributed to the oestrous cycle or nursing pups. Unfortunately, the question of spayed versus nonspayed females was not investigated. Young dogs were found more likely to bite people than were older dogs.

Perhaps the most striking finding is that certain breeds of dogs are more likely to bite people than other breeds. In this study, to facilitate analysis of the data, individual breeds were combined into groups of breeds, although there is a danger that the individual breed with a high rate of bites may be obscured by the rates of the other breeds in the group. Working dogs and sporting dogs clearly were reported to bite more people than would be expected. The differences between the expected and reported number of bites for these groups is probably significant. They did not result from age and sex variations within groups, and the circumstances of the bites did not account for these differences. There was not an unusually large proportion of bite accidents involving these breeds in which human acts provoked the dogs to bite. A random check of the records showed that improper classification of dogs by breeds was not a major source of bias. At this time, we are not able to single out individual breeds within the groups which are especially vicious. However, this preliminary study would seem to indicate that such breeds exist.

On the basis of the findings in this study, the following recommendations are suggested to dog owners.

- Try to avoid the combination of young dogs (less than a year old) around young children (less than 5 years old).

- When obtaining pets for children consider the fact that female dogs inflict more bites than male dogs.

- Restrain or dispose of dogs which consistently bite people.

- Immunize dogs against rabies, consulting a veterinarian for the proper schedule.

- Consult a physician in case of a dog bite.

- Obtain a license for each dog.

- Affix an identification tag to each animal's

collar, listing the dog's name and the owner's name and address.

- Don't permit dogs to roam at large in a heavily populated area.

Summary

Dog factors associated with dog bites in Pittsburgh, Pa., were studied by comparing the licensed dogs which bit people with the total licensed dog population of the city. Of 19,334 licensed dogs, 571, or 3 percent, bit people during July and August 1958.

Female dogs had a higher bite rate per 100 dogs than male dogs (4.1 and 2.7). The higher rate among female dogs could not be attributed to the oestrous cycle or to nursing pups.

Young dogs, 6-11 months of age, were found more likely to bite people than older dogs. Perhaps this finding is related to young dogs' lack of training and poor adjustment toward people.

Certain groups of dogs were found more likely to bite people than other groups. Working dogs were the chief offenders, with 48 bites expected and 90 bites observed. Also, sporting dogs bite people more often than would be expected. No individual breed could be singled out as especially vicious, but such breeds probably exist.

Some dogs are repeatedly involved in dog bite accidents. According to the owners and the victims, during 1 year between 47 and 83 dogs bit 2 people; at least 16 dogs bit 3 people; 1 dog bit 4 people; 1 dog bit 5 people; and 1 dog bit 8 people.

The findings in this epidemiological study of dog bites provided a factual basis for making recommendations to prevent and control dog bites.

Florence Rena Sabin

A pioneer in physiology and public health has been selected by the State of her birth, Colorado, as one of its two representatives in National Statuary Hall of the Capitol of the United States (see frontispiece).

Florence Rena Sabin, born in Central City, Colo., November 9, 1871, was the first woman intern to be accepted by Johns Hopkins University, in 1900, after earning a doctorate in science at Smith College; the first woman to be professor in a medical school (histology at Hopkins); and the first woman to be president of the American Association of Anatomists (1924).

Renowned for contributions to the dynamic study of functional physiology, Dr. Sabin was also the first woman to be invited to join the staff of the Rockefeller Institute of Medical Research, where she served 13 years until her "retirement" at 67 in 1938. Then she began one of the most vigorous periods of her career.

As chairman of the health section of Colorado's postwar planning committee and city manager of health and charities in Denver, she led a successful campaign for "Health To Match Our Mountains," which culminated in 1947 with legislative and financial support of a new department of public health, construction of new hospitals, a widened medical school program, increased facilities for tuberculosis management, and a strengthened system of milk sanitation.

Signs

and

Symptoms

of trends in public health

A full program of progressive patient care has been established at Grant Hospital in Chicago with the opening of a new wing. The hospital now has three 6-bed wards for intensive care and one 18-bed wing for ambulatory self-care. Intermediate care is provided in the remaining wards.

Trachoma in Mexicans in Southern California is under investigation by scientists assigned by the Communicable Disease Center of the Public Health Service.

» «

Properly designed and adequately fitted mouth protectors are urged for all youths engaged in contact sports by Dr. Gerard H. Schoen of the American School Health Association. He quoted a recent survey which showed that among a group of high school football players, 11 percent not wearing mouth protectors suffered dental injury while those with protectors escaped harm.

» «

The world's population is increasing at the rate of 45 million a year, according to the annual report of the United Nations Department of Economic and Social Affairs. The computation is based generally on an estimated annual birth rate of 34 per 1,000 and death rate of 18 per 1,000. Highest life expectancy was found in Norway where girls born now may expect to live to the age of 75, and boys may reach 71.

These and other statistics supplied by member governments are considered by the report's editors to be correct within a range of 75 to 98 percent.

The Declaration of Geneva rather than the Hippocratic Oath was taken at the first commencement exercises at Albert Einstein College of Medicine, Yeshiva University, New York City. Fifty graduating students pledged "not to use their medical knowledge contrary to the laws of humanity" or to "permit considerations of religion, nationality, race, party politics, or social standing to intervene between duty and patient."

The virus laboratory of the division of laboratories, New Jersey Department of Health, is now housed in new quarters at the Madden Building, Donnelly Memorial Hospital, Trenton.

Complete equipment for virus isolation and serologic studies of virus diseases has been installed during the past year, including housing for large and small animals. In addition to diagnostic virology, laboratory areas have been set aside for research tied in with the department's epidemiological services.

E. L. Shaffer, Ph.D., is director of the division of laboratories, and Martin Goldfield, M.D., assistant director.

Public opinion favors spending for medical research, according to a University of Michigan survey. Interviews of 1,500 Americans showed that, given a choice, 54 percent preferred medical research; 32 percent, efforts to combat juvenile delinquency; 7 percent, basic research in the sciences such as physics and chemistry; and only 3 percent, a program to put the first man on the moon.

A cooperative program of medical care for people on public assistance has resulted from joint action by practicing physicians, the department of public welfare, and the county health department in Russell County, Va., Dr. J. W. Jessee of Norton reports.

Three steps initiated the action. A screening facility was set up to determine the medical eligibility of welfare applicants. A medical advisory committee was formed to serve the department of public welfare. And the local health department arranged to coordinate medical services to the indigent sick.

A general medical clinic was opened in 1956 with local funds. State support was added after the clinic was designated as part of a statewide pilot study of coordinated medical care for the indigent sick.

Observations after 3 years of operation indicate there has been definite improvement of interworking relationships, opportunity for control and coordination of medical services to welfare patients, increased use of established health department programs, success in casefinding, and savings in costs both to the patient and to the community.

In the absence of equipment or help from a second person, the American Red Cross endorses the mouth-to-mouth technique as the most practical method of artificial respiration regardless of age and cause of cessation of breathing.

Industrial **CONFERENCE REPORT** Health Today

Air pollution, radiation exposure, poisons, the impact of sound, and their resultant challenge to current industrial health practices were among the major topics at the 1959 Industrial Health Conference held in Chicago, April 27-May 1.

The conference is conducted as a joint annual meeting of five professional organizations: the American Conference of Govern-

mental Industrial Hygienists, the American Industrial Hygiene Association, the American Association of Industrial Dentists, the American Association of Industrial Nurses, and the Industrial Medical Association.

Of the 109 papers presented at the 5-day meeting of the American Industrial Hygiene Association, 16, selected for public health interest, are summarized here.

Planning for Radiation Accidents

The probability that accidents resulting in serious levels of radiation exposure will increase in the coming decade seems likely because of the tremendous growth in the use of this modality in industry. Prompt notification of the possibility that a radiation accident might have occurred is essential for the most effective handling of the situation. Rapid communication between health personnel and management is vital.

Once the event occurs, it is essential to restrict exposure from sources of radiation outside the body, from radioactivity on the body surface or within the body, or from a combination of these sources.

If radioactive elements are released, they can be disseminated rapidly. Evacuation and closure of the hazardous area must be carried out immediately. The first 12 hours are critical. Diagnostic studies should be instituted and decontamination procedures planned and started at once.

Monitoring of individuals in an emergency requires certain hematological studies as well as careful medical observation. Specific medical therapy depends on the levels of radiation and kinds of contamination found or suspected. Collection of specimens of blood, urine, feces, and breath may be needed to determine what particular radionuclides are at large.

The relationship between the physician and health physicist and administrative problems, particularly in relation to publicity, are especially important and require planning and

direction. If contamination threatens the general public, civic authorities have responsibilities to contain the danger.

Aid in radiation accidents is available from the Atomic Energy Commission and Department of Defense.—EUGENE L. SAENGER, M.D., *College of Medicine, University of Cincinnati, Ohio.*

Experience With Occupational Overexposure to Radiation

Nineteen incidents of excessive exposure to radiation have been reported to the New York State Labor Department since the promulgation of the State industrial code a little more than 3 years ago. Excessive exposure to radiation is defined in the code's rule 38 as a dose in excess of 3 rems during a 13-week period.

Eight of the reported incidents appear to have been false alarms. In seven, reports were based upon an erroneous measurement of exposure due to improper handling of radiation measuring devices. For example, excessive readings on several film badges resulted from their storage in a highly radioactive area. In the eighth incident, prompt evacuation of an area following an accidental spill of strontium-90 prevented overexposure. There was no discernible clinical evidence of injury in any of the eight instances.

The 11 other incidents were produced either through chronic low-level routine exposures ranging from 0.4 to 1.2 rems per week, exceeding the recommended limit of 3 rems per 13 weeks of penetrating radiations from radioactive material; or through acute high-level accidental exposures to X-rays or radioactive materials, with dosages ranging from 30 to 1,200 rems. Acute exposures were fortunately confined to noncritical areas of the body.

In three individuals exposed, radiation burns were determined to have originated after the code went into effect. Remedial measures have been taken in the plants where these exposures were reported.

The factors most frequently responsible for excessive exposures were lack of awareness of

the hazard, of proper supervision, of proper work techniques, and of adequate protective devices.—MORRIS KLEINFELD, M.D., AND ALBERT P. ABRAHAMS, *New York State Department of Labor, New York, N.Y.*

Protective Clothing at a Large Atomic Energy Installation

Protective clothing is worn at atomic energy facilities primarily to keep radioactive materials away from the body and to insure that contaminants are not inadvertently removed from controlled areas. This clothing is a vital but costly aspect of any radiological health program.

At the Savannah River plant, the investment in clothing and laundry facilities is sufficient to justify a continuous program for reducing this expenditure without compromising the necessary protective standards. Major effort has been directed toward evaluation and standardization of existing equipment, evaluation and development of new types of garments, and revision of laundering processes.

Projects which were successful in increasing the protective value of garments include:

- Testing and adoption of a new coverall fabric which provides greater protection against penetration of particulate matter.
- Development of water vapor permeability data which are used in the selection and specification of rubber and plastic garments.
- Evaluation and adoption of extra large cloth gloves, cloth shoe covers, and cloth boots which allow for shrinkage and which are fabricated with seams strengthened against holes and tears.
- Requirement of a large strap on coveralls and laboratory coats to permit pocket chambers and badge dosimeters to be worn in a central and consistent location.

Projects which have resulted in substantial savings without compromising protective standards include:

- Use of unbleached clothing.
- Elimination of unnecessary pockets on coveralls and laboratory coats.

Clothing worn in the laboratory at the U.S. Atomic Energy Commission's installation at Oak Ridge, Tenn., is monitored for evidence of radioactivity. Some laundry must be confined as waste, if it is found to be unsafe.

- Recovery of coveralls contaminated to slightly above normal reuse limits to serve as outer "throwaway" garments following work in highly contaminated areas.

- Development of a two-piece plastic suit which is far less expensive than the previously used one-piece suit.

- Development of a process for satisfactorily recovering contaminated surgeons' gloves for reuse.

In addition to continuously evaluating newly developed and marketed products, future work includes establishment of a program to dry-clean and reclaim contaminated leather gloves.

This information was developed during the course of work with the Atomic Energy Com-

mission under contract AT (07-2)-1.—R. W. VAN WYCK AND H. L. BUTLER, *E. I. duPont de Nemours and Co., Aiken, S.C.*

Survey of Radiation Received by Dentists and Dental Assistants

A 9-year survey of personnel engaged in dental radiography in New England, when compared with similar surveys of physicians using X-rays, showed that dentists and dental technicians rank third among the health professions in weekly dose received.

The survey was accomplished by using film badges worn on the lapel or carried in a pocket, and an attempt was made to maintain the same relative distance from the floor. Ionization survey meters were used to check the installation and the pattern of scatter.

Analysis of 3,134 badges from 233 dental offices and 3 clinics showed the following results for an average 2-week period:

<i>Exposures (in milliroentgens)</i>	<i>Personnel monitored (approximate percent)</i>
0-9.....	17
10-99.....	50
100-199.....	20
200-299.....	10
Over 300.....	3

Exposures of more than 200 milliroentgens were due largely to carelessness and the shortcuts taken by technicians working under pressure. Many dental radiography units had no added filtration and most were not properly diaphragmed. Rooms were usually small, thus precluding the possibility of using distance as a protective measure.

A phantom was used to take radiation measurements, but the many applicable variables made it impossible to determine the least hazardous operating position for dental personnel. The only safe place is outside the room. Second choice for safety is a position away from the zone of scattered radiation, less than 120 degrees from the primary and at least 3 feet from the X-ray tube head.

After checking installations for scattered radiation, reevaluation by film badges, proper utilization of filters and diaphragming, and advice to personnel on safer procedures, there was an appreciable decrease in milliroentgens received by the dental personnel surveyed.—
CHARLES K. SPALDING AND RUSSELL F. COWING,
New England Deaconess Hospital, Cancer Research Institute, Boston, Mass.

Engineering Efforts in Noise Control

Modern high-speed equipment, powerful automatic machines, jet engines, and rockets have drawn attention to the need to protect the hearing of operating personnel from destructive

effects of noise. Concerted efforts have been organized to define the acceptable limits of noise exposure, to control noise, and to protect personnel.

The risk of hearing impairment associated with any given noise depends not only upon the noise level but also upon the length of exposure. In evaluating a working environment and in choosing suitable steps to reduce exposure to noise for operating personnel, it is necessary to consider noise levels throughout the field of operation, the work schedule, and the movements of the operator.

When a new plant or process is being considered, advance planning helps to achieve effective and inexpensive noise control. A careful choice of machine location, plant design, and construction materials at the planning stage can reduce the noise hazard significantly and may eliminate it completely. Modifications required for noise control can be made more effectively on the chosen machines or processes before installation is completed.

If a plant or process is in operation, noise exposure may be reduced by revising work patterns, by using corrective acoustic design, or by protective devices. Relocation of an operator, even by a few feet, may reduce his exposure to noise significantly or may permit the use of measures which would be ineffective in the previous position. Modifications to a machine or the provision of effective noise shields requires careful design engineering, but basic noise control principles have been developed which can simplify the design procedure.

For example, if the person to be protected is close to the source of noise, an enclosure for the source or even a partial enclosure or a baffle will be effective in reducing the direct sound by reflecting it away from the listener. In this position, however, the addition of acoustic tile to the ceilings or walls will provide little relief since such material will reduce the reflected sound only, and this sound is already low in comparison with the direct sound. Conversely, when the person is far from the source, acoustic absorption spread around the room may be quite effective.

Ear muffs, ear plugs, or similar ear protective devices are generally the least desirable noise control technique because of the inconvenience

and difficulties inherent in obtaining proper fit and adjustment. Sometimes, however, they are the only practical solution.

When processes and machines are intrinsically noisy and their functions cannot be dissociated from their noise output, a realistic answer may be found in the use of automation and remote control.—CLAYTON H. ALLEN, PH.D., *Bolt, Beranek & Newman, Cambridge, Mass.*

Medical Critique of Noise Control

In 1947, there was an abrupt increase in the number of compensation hearing loss claims in the State of New York. Shortly thereafter, many similar claims were filed in New Jersey, Wisconsin, and other States. Despite these developments, the hearing hazard has awakened little concern in a large number of industrial plants.

Improper and unsatisfactory hearing conservation programs may be due to many factors. To mention a few, they include poor planning, noisy testing environments, the use of improperly trained technicians, questionable testing techniques, unsatisfactory recording, and particularly the lack of proper medical supervision.

There are industries which have purchased audiometers and turned them over to nurses or safety personnel with instructions to make "hearing tests." These records are merely filed for use in the event of future claims. No provisions are made for adequate training of the personnel conducting the tests, for medical supervision, or for proper interpretation. Any hearing conservation program without medical supervision must be considered inadequate.

For industrial hearing testing programs, a simple discrete air conduction audiometer properly calibrated and maintained is all that is required. This audiometer may be a small portable or an office model. Additional equipment, such as bone conduction, speech circuits, and masking, are not essential for implant testing. The hearing test performed should be a pure tone air conduction threshold audiogram, not to be confused with so-called screening

tests which use a single- or two-frequency technique and are intended for recheck or periodic examinations.

Poor planning and the use of elaborate equipment and testing procedures lead to unnecessary expense and often to misleading and unreliable information.

There has been considerable misunderstanding of what is meant by "noise exposure" and failure to realize when ear protective measures are indicated. Much of this misunderstanding can be overcome by proper educational campaigns and approaches which will help to reduce resistance to protective steps.—MEYER S. FOX, M.D., *2040 W. Wisconsin Avenue, Milwaukee, Wis.*

Legal Aspects of Noise Control

Granting workmen's compensation benefits in cases of occupational deafness for purely physiological or social loss where there is no loss or impairment of earning capacity has resulted in numerous complicated medicolegal and socioeconomic problems.

The new formula recently proposed by the Subcommittee on Noise of the American Academy of Ophthalmology and Otolaryngology does not make any provision for the nonmedical, legal, and economic factors which must be considered in the establishment of a "disability formula" as distinguished from an "impairment formula."

The medical and related sciences should yield basic data concerning the handicap or impairment caused by hearing loss. It would then become the function of the legislative or administrative authorities to determine at what point and to what extent the handicap becomes a compensable industrial liability within the meaning of the Workmen's Compensation Law. The data should include what is known about the extent of hearing losses among the general population caused by presbycusis, sociocusis, and nonoccupational disease so that in estimating the auditory effect of occupational noise exposure a uniform, corrective factor can be applied, on a statistical basis, to the audiogram to

cancel out the loss which may reasonably be assumed to have been caused by these other non-industrial elements.

Because of the difficulties of proof with respect to etiology and many uncertainties inherent in the problem, it would not be feasible or practical to handle this matter on an individual case basis. In cases of occupational loss of hearing, compensation should be paid only for the hearing impairment which is in excess of the degree of hearing impairment found in the average individual at different age levels among the general population not exposed to harmful industrial noise.

In any suitable disability formula, some recognition should also be given to the extent, if any, to which the employee's hearing impairment affects, or may in the future affect, his earning capacity.

Another question for which no satisfactory legal solution has been found to date is how to allocate compensable liability in the case of exposure to harmful noise in successive employments.—NOEL S. SYMONS, of the law firm *Vaughan, Brown, Kelly, Turner, and Symons, Buffalo, N.Y.*

Experimental Cancers Produced in Rats by Chromium Compounds

Numerous studies have failed to identify the agent responsible for the high incidence of cancers of the lung among chromate workers. A previous study provided highly suggestive evidence that the roasted chromite ore contains a carcinogenic agent. These and other observations indicated that the development of experimental tumors depended on the proper biological availability of chromium to the tissues, determined largely by the relative degree of solubility of the chromium compound present. The present study was undertaken to test the validity of this concept.

A series of chromium compounds covering a wide range of water solubility and including calcium chromate, sintered calcium chromate, sintered chromium trioxide (chromic chromate), barium chromate, strontium chromate, zinc chromate, and lead chromate were implanted surgically in the muscle tissue of the thighs and in the pleural cavities of Bethesda black rats. Each compound mixed with sheep fat was administered to 70 rats, 35 for each site.

Tumors produced in rats by chromium compounds

Compound and site of implant	Number rats living	Number rats dead	Number with tumors at site of implant	Percent of dead with tumors	Percent of tumors in total group	Observation period (months)
Calcium chromate (2,470):						
Pleural.....	0	35	21	60	60	18
Thigh.....	13	22	9	41	26	18
Sintered calcium chromate (1,280):						
Pleural.....	3	32	17	53	49	19
Thigh.....	7	28	9	32	26	19
Sintered chromium trioxide (1,710):						
Pleural.....	7	28	20	71	57	17
Thigh.....	4	31	21	68	60	17
Zinc chromate (610):						
Pleural.....	23	12	7	58	20	9
Thigh.....	26	9	9	100	26	9
Strontium chromate (230):						
Pleural.....	18	17	7	41	20	11
Thigh.....	21	14	8	57	23	11
Barium chromate (8.5):						
Pleural.....	16	19	1	5	3	17
Thigh.....	18	17	0	0	0	17
Lead chromate (<1):						
Pleural.....	34	1	0	0	0	9
Thigh.....	33	2	1	(50)	0	9
Sheep fat:						
Pleural.....	18	17	0	0	0	18
Thigh.....	16	19	0	0	0	18

NOTE: Figures in parentheses show the solubility in water of hexavalent chromium in milligrams per liter.

An equal number receiving sheep fat only were used for controls.

Five months after the material was implanted, the first tumors were observed in those rats receiving calcium chromate, sintered calcium chromate, sintered chromium trioxide, strontium chromate, and zinc chromate. Tumors occurred at the site of implantation in the thigh and in the pleural cavity (see table).

Animals receiving barium chromate and lead chromate developed tumors less frequently and after a longer latent period. The tumors were predominantly sarcomas and were highly invasive. A few intrathoracic cancers were pulmonary squamous cell carcinomas. In the pleural cavity, the tumors were usually adherent to the thoracic wall or diaphragm and frequently involved the lungs and other organs. In many of the animals part of the implanted material was observed embedded within the tumor.

These results, together with available epidemiological and clinical evidence, indicate that chromium is a carcinogenic agent if it is available to the tissue in proper dosage and form. Human lung cancer hazards may be associated, therefore, not only with the production of chromium chemicals and chromium pigments manufactured from chromite ore but also may occur with many other industrial and general uses of chromium metal and chromium compounds. Epidemiological studies on the frequency of lung cancers from such sources and in such industries and environmental conditions are lacking at present. The authors have compiled as a guide for epidemiological surveys a list of chromium products and operations and their industrial and environmental distribution.—W. C. HUEPHER, M.D., AND WILLIAM W. PAYNE, *National Cancer Institute, Public Health Service.*

Relationship of Bladder Cancer to Metabolism of Aromatic Amines

Bladder cancer associated with such aromatic amines as 2-naphthylamine is believed to arise not from the original compound but rather from a biochemically changed product present in

urine. An understanding of the mechanism of carcinogenesis from such materials would help in devising protective measures and would aid in predicting the probable carcinogenic potential of analogous substances.

For these reasons a major search is on for the carcinogenic urinary metabolite. The remarkable species specificity of the disease has offered one approach to this problem. Only humans and dogs develop bladder cancer when exposed to carcinogenic amines; rabbits, rats, mice, and other animals tested are not sensitive. The most common compounds found in the urine of all species exposed to 2-naphthylamine are the sulfate and glucuronide conjugates of the O-hydroxyamines. We have recently observed two compounds only in human and dog urine, 2-amino-1-naphthol and bis-2-amino-1-naphthylphosphate; 2-amino-1-naphthol appears to arise from an unstable precursor in these urines. If this precursor is only the identified phosphate conjugate remains to be tested.

The occurrence of these unusual compounds only in the species which contract bladder cancer appears a promising clue in the mechanism of bladder cancer formation.—WALTER TROLL, PH.D., *Institute of Industrial Medicine, New York University, Bellevue Medical Center, New York City.*

Epidemiological Findings Associated With Beryllium Extraction

Approximately 100 case histories of patients with alleged beryllium disease have been analyzed by the physicians of the division of occupational health of the Pennsylvania Department of Health. These illnesses were diagnosed by the medical profession over the past 20 years from the approximately 4,000 persons employed in a beryllium extraction plant in Pennsylvania or living in its vicinity.

Sixty cases of chronic beryllium disease were studied following a thorough examination of hospital records, personal contacts with physicians, and interviews with the affected persons or their surviving relatives. These cases were divided into three groups: persons who con-

tracted the disease as beryllium plant employees; persons having contact with work clothes of plant employees; and persons living in the neighborhood of the plant.

Only histories of patients with known chronic illnesses were selected. Figures are not complete since new histories are being added because of the latent period, frequently long in duration, before beryllium disease becomes evident clinically.

A study of air pollution in the plant vicinity was conducted at the same time as the clinical examinations. It was found from routine autopsy that many lung specimens from residents of the plant vicinity contained detectable amounts of beryllium despite the fact that there was no evident beryllium disease.—JAN LIEBEN, M.D., M.P.H., AND FRANZ METZNER, M.D., M.P.H., *Pennsylvania Department of Health, Harrisburg.*

Diethylstilbestrol Effects on Workers

Since 1941, the absorption of diethylstilbestrol has been producing gynecomastia and other symptoms in chemical workers. A suggestion by Dr. K. C. Kohlstaedt led to the development of a bioassay method, modified from that of H. D. Lawson and associates, to measure urinary output of diethylstilbestrol in workers once a week for early detection of excessive absorption.

Ten immature female mice (CF-1 strain) weighing 8 to 10 grams receive 0.2 ml. untreated urine orally on 3 successive days. Two control series of 10 mice each receive 3 similar oral doses of diethylstilbestrol, standard solutions containing 0.06 and 0.18 micrograms per milliliter respectively. On the fourth day, all mice are killed with CHCl_3 , and the uteri are dissected and weighed in groups of 10 to ± 0.1 mg. Typical average uterine weights relate to dose of diethylstilbestrol as follows: zero dose, 8 mg.; 0.06 $\mu\text{g}/\text{ml.}$, 16 mg.; 0.18 $\mu\text{g}/\text{ml.}$, 31 mg.

Unexposed chemical workers excreted estrogens below the threshold of the test (0.02 $\mu\text{g.}$ per milliliter). Exposed and imperfectly protected workers showed values ranging from 0.06 to 0.55 ($\mu\text{g}/\text{ml.}$). Earliest symptoms of breast stimu-

lation were seen 1 to 2 weeks after urinary excretion reached or exceeded 0.1 $\mu\text{g}/\text{ml.}$

Elaborate precautions similar to those used in handling radionuclides were required to prevent absorption: isolation in a room with tiled walls, caps, dust masks, coveralls, rubber gloves, entrance and egress through a shower, daily change of clothing, special laundering methods, filtration of exhaust air, and scrupulous cleaning up of spills. Even with this care, certain workers had to be rotated off the job because of early signs of absorption.—R. M. WATROUS, M.D., AND R. T. OLSON, B.S., *Abbott Laboratories, North Chicago, Ill.*

Factory Heat Waves Can Be Broken

Heat relief measures for operating personnel have been undergoing drastic reevaluation and revision. As a result, surprising changes are at work in the design and equipment of new plant buildings. These changes are in a chronic race with the increase in heat production.

Each year more heat is released as equipment increases in size and number. Machine tools are more heavily motored; departments accommodate more machinery. The drive to raise productivity also promotes faster heating rates and greater tonnage output by furnaces in fields of annealing, heat treating, billet heating, and alloying. At the same time, building characteristics are changing in ways that hinder conventional ventilation practices. Long, narrow buildings that have aided cross-ventilation are disappearing and ventilation courtyards are being swallowed up. Furthermore, the vast expanses of glass sash wall construction pour solar heat into buildings; about 6 square feet of clear unshaded window glass can introduce as much heat into a building as a pound of steam.

Thus two opposing forces of industrial importance are meeting in head-on collision. Plant design trends stifle conventional ventilation methods at the same time that more heat release requires more and better ventilation. Indoor heat problems are being cleared up reasonably well by three simple procedures.

In the majority of cases, the cooling agent is air motion or circulation using air fresh from

outdoors. For these summer benefits, outdoor air can be taken in from levels slightly above the roof by a popular type of roof exhaust ventilator that is operated with reverse fan rotation to blow in large volumes of air at extremely economical cost. Locations can be selected to suit hot local area requirements. Refinements, where justified, can include air pattern distribution diffusers that are adjusted by a pull chain installed in the floor.

Severe heat cases involve operations such as molten metal, hot metal furnaces, kilns, and engines. The most severe cases usually involve the same plant operations as in heat shielding, but there is the added problem of high building ambient, or air, temperature. To overcome this combination, controlled air motion is supplied but can be doubled in effectiveness by use of water sprays for evaporative cooling. For scattered problem areas, individual so-called desert coolers serve.—BARTLETT R. SMALL, P.E., *Aluminum Company of America, Pittsburgh, Pa.*

Forecasting Air Pollution

On the premise that it might be practical to alert industrial plants against untimely discharges of wastes to the atmosphere, a procedure for forecasting meteorological conditions which are conducive to high pollution levels over a large area was tested during the fall of 1957 and 1958 by the Weather Bureau Research Station at Cincinnati, cooperating with the national air sampling network of the Public Health Service.

Tests of the alerting system were conducted from 33°N. to 43°N. and 78°W. to 88°W. Air quality measurements were taken on request by selected stations of the national air sampling network. A request was issued whenever the following meteorological phenomena occurred simultaneously and a forecast indicated they would persist for at least 36 hours:

1. Surface winds less than 8 knots.
2. Winds at no level below the 500 mb. pressure level to exceed 25 knots.
3. Subsidence below 600 mb.

During the fall of 1957 and 1958, six periods were observed in which the selected empirical

criteria were met. Air quality data were obtained for five of these periods.

Examination of the air quality data for the periods in which the weather was monitored revealed that the highest loadings, with few exceptions, occurred in those periods when the criteria were met. Although derived from limited data, the results indicate that macro-scale meteorological phenomena can be used to signify periods of high pollution potential for a large area. However, general application will require interpretation of pollution-potential forecasts in terms of anticipated concentrations of specific pollutants.—L. E. NIEMEYER, *Weather Bureau Airport Station, San Francisco, International Airport, San Francisco 28, Calif.*

Relationship of Street Level Carbon Monoxide Concentrations to Traffic Accidents

In Germany and the Scandinavian countries, investigators have reported extensive observations concerning carbon monoxide exposures insufficient to cause subjective symptoms but which affect the cardiovascular, endocrine, and respiratory systems, the blood, and the central nervous system, causing disturbances of vision, hearing, speech, and the reflexes.

Since a disturbance of vision and reflexes can be predisposing to traffic accidents, research was begun in 1956 to determine whether carbon monoxide as an atmospheric pollutant may be hazardous in urban areas.

To determine the CO in the atmosphere, three recording infrared CO analyzers were set up at various locations in Detroit. The full-scale reading of each instrument was 100 parts per million with reliable readings as low as 1 ppm. For a period of 27 weeks, a recorder was located on a depressed highway within the city. The data obtained at this station showed CO readings ranging from 0 to 100 ppm with a median of approximately 8 ppm. Another recorder was placed in a busy neighborhood shopping area for 58 weeks. The CO readings at this location ranged from 0 to 100 ppm with an approximate median of 10 ppm. For 21

weeks a recorder was operated in downtown Detroit and, here again, the CO concentrations ranged from 0 to 100 ppm with a median of approximately 9 ppm. The CO in the atmosphere of the residential area was sampled for 18 weeks. These readings ranged from 0 to 29 ppm with a median of only 2 ppm.

Data obtained from these infrared analyzers were tabulated first by quarter hour and then by hourly intervals, and then correlated with other factors, such as traffic count and meteorological conditions, which were also recorded on an hourly basis. From these data, we are attempting to predict the conditions which permit dangerous concentrations of carbon monoxide to be created in the atmosphere.

Another phase of the study included taking blood samples from drivers and pedestrians involved in automobile accidents to determine the percentage of CO saturation. A total of 227 blood samples have been analyzed and the results ranged from less than 0.5 to 31.5 percent saturation with an approximate median of 1.7 percent.—GEORGE D. CLAYTON, *George D. Clayton and Associates, Inc., Detroit*, WARREN A. COOK, *School of Public Health, University of Michigan, Ann Arbor*, AND W. G. FREDRICK, *Sc.D., Department of Health, Detroit*.

Air Pollution Inventory

In an effort to evaluate specific levels of emission of air pollutants characteristic of industries in Michigan, a door-to-door survey of industrial establishments was conducted in certain portions of Wayne, Macomb, and Oakland counties by the Michigan Department of Health in cooperation with the Public Health Service. The total emission, exclusive of combustion resulting from power generation and heating, amounted to 976 tons per day from an estimated 80 percent of the contributing establishments surveyed.

The study was concerned with the industrial process effluents, and accordingly, all types of manufacturing plants were included, with the exception of domestic and commercial establishments, transportation facilities, and power generation facilities.

Analysis of the data indicates that the steel

mills in the area account for more than half of the total pollution load, with automobile manufacturing, petroleum refining, inorganic chemical manufacture, gasoline and oil storage and handling, the manufacture of concrete and concrete products, and the manufacture of asphalt, all contributing lower but nevertheless large amounts of contaminants to the atmosphere.

The study obtained a complete inventory of air pollutants by industrial category, specific process giving rise to the pollution, composition of the pollutants, and the amount of material emitted. Industrial categories are tabulated and numbered in accordance with the new Standard Industrial Classification Manual (U.S. Bureau of the Budget, 1957).—BERNARD D. BLOOMFIELD, *Michigan Department of Health, Lansing*.

Five Years of Continuous Air Monitoring

Since May 1, 1954, outdoor air at roof level of a six-story building on the University of California campus has been monitored continuously for particulate material with the ACSI smoke sampler. The instrument filters twelve 2-hour samples per 24 hours (about 30 cubic feet per sample). The interpretation of darkening of the filter paper is based on photometric light transmission through the soiled paper and finally recorded as COH units per 1,000 linear feet of air through the filter.

On the average, the 5-year data show a consistent maximum of particulate pollution near midday on all days of the week. The average 24-hour pollution is lowest on Sundays, highest from Tuesday through Friday, and at an intermediate level for Saturday and Monday.

This difference is clearly demonstrated when the average data for these several days of the week is plotted on a log probability graph as suggested by analysis of results from the national air sampling network. Compilation of the filter-soiling data by this technique strongly indicates that the average information is internally consistent except at low COH readings.

Seasonally, the record shows relatively high pollution during the months of October

through January, relatively clean air from March through August, and intermediate results in the other months. When plotted by the log probability method, the seasonal data were not correlated so satisfactorily as were the annual data.

Since observations during the first 3 years were essentially similar both in annual average and in correlation by the log probability method, they have been used as a baseline for

comparison of subsequent annual trend. The fourth year showed significantly less pollution than the baseline years. An average decrease of 25 percent is attributed more to meteorology than to inauguration of the area's first air pollution control regulation. The fifth year of observation, starting May 1, 1958, showed a return of the average pollution toward that of the baseline years.—BERNARD D. TEBBENS, Sc.D., *University of California, Berkeley.*

Disability Days in the United States, 1957-58

As a result of illness and injury, workers with family incomes under \$2,000 per year lost an average of 10.3 days from work during the 12 months ending June 30, 1958, as compared with a loss of 5.9 days for those in families earning \$7,000 and over, according to the latest of a series of published statistical reports issued by the U.S. National Health Survey, Public Health Service. The data, applying to the total civilian population of the country, exclusive of persons confined to long-term institutions, are derived from continuing household interviewing with a representative sample of the population, conducted for the Service by the Bureau of the Census.

An inverse relationship existed also between income and other forms of restricted activity, such as days in bed due to illness and injury.

Workers 65 years of age and over lost about 11 days from work compared with 8.4 days for those in the group 45-64 years and 6.3 days for those aged 17-44. City children lost

9 days from school, on the average, as a result of illness and injury; rural nonfarm children lost 7.8 days; and farm children lost 7.3 days. However, farm children 15 and 16 years of age lost about 10 days from school as compared with 6.5 days lost by urban children of these ages.

Respiratory illnesses as a group were responsible for 40 percent of all activity restriction and half of all days in bed. Circulatory diseases ranked second in terms of total volume of disability, followed by injuries and their chronic effects and then digestive diseases.

The publication contains additional data on the relation between disability and various characteristics of the population, giving details by calendar quarter. Copies of the report, "Disability Days, United States, July 1957-June 1958," PHS Publication No. 584-B10, may be obtained from the Superintendent of Documents, Government Printing Office, Washington 25, D.C., at 40 cents a copy.

By reviewing the historical background of hospital regionalization, researchers are aided in applying the techniques of industrial engineering to the problem of improving the efficiency and economy of hospital services in geographic regions.

Hospital Regionalization in Perspective

MILTON I. ROEMER, M.D., and ROBERT C. MORRIS, M.S.

REGIONALIZATION of hospital services has become a popular theme in the United States. Since 1947, State master plans for hospital construction under the Federal Hill-Burton Act have been based on this concept. Regional and metropolitan hospital councils are set up in 11 States. Insurance commissioners, faced with rising Blue Cross premiums, have called for regional coordination of hospitals to reduce costs (1). A series of conferences has been held across the Nation on planning hospital systems, in which regional organization is the key problem. Seasoned hospital leaders call for more research in the field (2).

But the meaning of "hospital regionalization" is not always clear. To some it is simply an approach to making decisions on where hospital buildings are needed and how many beds should be provided at each location. To others it means a systematic scheme for cooperation among hospitals in their day-to-day operations. To a European, it usually implies unified management of a network of hospitals

in a geographic region. And there are other defined points in the range of possible meanings.

In fact, hospital regionalization has had different meanings historically, and it has different meanings today in different parts of the world or different places in the United States. Perhaps the only common note in all the interpretations is an element of coordination, in planning construction or in actual operations or both, among a group of hospitals in a geographic region. Ways of expressing this coordination vary greatly. The intention is always to give the hospital program a rational structure in order to improve the quality of service or reduce the costs or both. But whether this goal has actually been achieved by regionalization efforts or how it might be best achieved are large questions to which we do not have answers.

If we take a closer look at the hospital regionalization movement, we may gain perspective in designing research to answer these questions.

Dr. Roemer is director of research, Sloan Institute of Hospital Administration, Graduate School of Business and Public Administration, Cornell University. Mr. Morris is a research associate on the staff. This paper was prepared for presentation at the Rochester, N.Y., Regional Hospital Council meeting this fall.

Historical Background

It is customary in the United States to trace the origin of the hospital regionalization idea to the program of the Bingham Associates Fund operating in Maine since 1936 (3). Here was an effort to bring first-class modern scien-

tific medicine to residents of the rural areas and small towns of Maine. The emphasis was on improved resources for medical diagnosis. The base center is in Boston, where difficult cases are sent. Then there are two regional or district hospitals in the principal cities of Maine and 38 cooperating small community hospitals around them. More recently western Massachusetts has been added to the program. In this area four larger hospitals, lying close together, jointly serve as a regional center for 10 smaller community hospitals. Laboratory specimens and X-ray films are sent from the community hospitals to the regional centers for examination, and consultants go outward from the centers to advise the rural doctors. Physicians are encouraged to come to the centers for postgraduate education. Consultation is also offered in nursing, dietetics, medical record-keeping, and other aspects of hospital administration.

This program, with its two-way flow of patients and services, now the hallmark of the regionalization concept, was built with outside philanthropic support. Certainly the quality of services in the smaller hospitals has been improved, but we have little, if any, idea of the relative costs and whether the same end might be served in other less expensive or more effective ways.

The basic idea of hospital regionalization, however, is much older than the Bingham program. In Denmark, around 1912, the decision was made to avoid further building of rural hospitals and to bring patients with complicated illnesses from rural areas to the central hospitals. A network of institutions was developed, centering in Copenhagen and branching out to the whole country (4).

In 1920, there appeared an English study on improving hospital services which described the basic scheme embodied in the British National Health Service 28 years later. The Dawson report called for establishment of a network of hospitals within which all services could be integrated. It defined primary and secondary health centers and recommended that the smaller units, staffed mainly by general practitioners, be supervised by the larger ones, staffed mainly by specialists. The report even sketched prototype centers, showing buildings

and layouts and listing services to be performed (5).

Military medical establishments have long been organized on a regional scheme, with base hospitals, division or theater-of-operation hospitals, and field stations. Highly systematized, of course, these hospitals demonstrate the feasibility of actual administration of many institutions by a central authority.

Colonial governments have likewise operated hospital systems through central authority. In Asia and Africa, there are capital and district hospitals, with small health centers or mobile clinics at the periphery. Countries liberated from colonial domination, such as India or Indonesia, have usually retained and developed these regional hospital networks.

With one or two exceptions, Catholic sisterhoods do not operate regional hospital networks, but they have long exercised central authority over certain aspects of their hospitals which may be located in scores of far-flung communities. Funds are pooled which may be channeled to provide construction and equipment wherever it is most needed, and uniform administrative policies are usually enforced.

These are expressions of the hospital regionalization concept originating many years ago. In fact, if we think of regionalization as a range of activities, we must go back even further. For any step of a hospital from isolation and self-sufficiency toward interdependence with other agencies or organizations is fundamentally a move in the direction of regionalization.

Thus we can visualize a hospital in colonial America, such as the Pennsylvania Hospital in 1751, as an institution quite alone. The staff may not have grown their own food for hospital use, but surely they made most of their own bandages and supplies. There was, moreover, little to be purchased from the commercial market. There were ideas brought from Europe, but their implementation was entirely up to the small staff working in this solitary structure.

As other hospitals were established, as industry grew, as medicine developed, the hospital obviously became less isolated. Equipment and supplies were produced by industrial companies. Educational institutions trained skilled personnel needed to staff the hospital.

A public health laboratory did tests on hospital patients. A State agency was given legal authority to approve certain aspects of hospital construction or operation. Money to support services for certain beneficiaries was derived from diverse public and voluntary agencies. Associations of hospitals were formed for educational and promotional purposes.

In different countries, this process of dynamic inter-relationship among hospitals has evolved in different ways and to varying degrees. In general, the process has gone further in countries where governments at all levels, national, provincial, or local, have become largely responsible for the ownership and operation of hospitals. This is, indeed, the predominant pattern in Europe, Latin America, Asia, and in fact the entire world outside the United States and Canada (6).

Even in the United States, however, the regionalization process has been clear and gaining momentum. Much of it has been on a casual, spontaneous basis. Patients are transferred from one hospital to another. Equipment is sometimes lent. A radiologist based in one hospital interprets films sent by another. A blood bank in one hospital sends a pint of blood to another.

Other expressions of the process toward integration and coordination of hospitals have been more formal and systematic. The Bingham program has been mentioned, and it is historically important not only for the specific mechanisms it pioneered but also for the attention it focused on the need for improved medical care in rural areas.

As America has become industrialized and urbanized, the rural areas have, in a sense, been left behind. The same is true all over the world. A special consciousness of the problems of rural medical care emerged in the 1930's. The first conference on rural medicine was held at Cooperstown, N.Y., in 1938. The Bingham program in Maine got started. The Commonwealth Fund launched its program of building rural hospitals and supporting medical education for rural youth. Improved public health organization in rural counties was promoted. The U.S. Department of Agriculture started its medical care program for low-income farmers (7).

It was during World War II that the regionalization idea matured as an approach to improved hospital service for rural people. Public understanding grew and plans were made for a federally subsidized construction program. In 1945 the Commonwealth Fund promoted the Council of Rochester Regional Hospitals (8). Immediately after the war, in 1946, the National Hospital Survey and Construction Act was passed, providing not only funds to subsidize hospital construction but requiring a master plan to be drawn up by each State establishing priorities for different localities. Virtually everywhere the rural areas received top priorities because their relative bed shortages were greatest (9).

Under the impetus of the Hill-Burton Act, planning groups studied bed needs in all the States. A formula calling for 4.5 to 5.5 general hospital beds per 1,000 population in a State made planning for construction purposes relatively easy. Planning for coordinated hospital operation, however, was not so easy. Attractive charts portrayed networks of regional, district, and community hospitals in each State, implying the classic two-way flow of patients and services. In practice, the State hospital construction agencies were seldom in a position to bring life to the charts in day-to-day hospital operation.

Coordinated Operations

Nevertheless, the introduction of rationalism into construction planning stimulated voluntary groups to do something about coordinating hospital operations.

National attention was focused on the regionalization experiment around Rochester. Elsewhere in New York State regional hospital councils were organized, not simply to process applications for construction funds but to promote interhospital cooperation (10).

State hospital associations became organized or revitalized. They conducted educational and informational programs for their members. Training institutes were held for hospital trustees and administrators as well as for nurses, dietitians, medical record librarians, laboratory technicians, and business office personnel. Uniformity was introduced into ac-

counting practices so that hospitals could deal effectively with third-party payers, such as governmental welfare agencies or Blue Cross hospital insurance plans.

The hospitalization insurance movement did a great deal to bring autonomous hospital administrations together. Through boards of directors of regional Blue Cross plans, hospital advisory committees, and other mechanisms, administrators discussed common problems of hospital operation. Many of these problems are expressed ultimately in per diem costs which the prepayment plan is expected to meet. To sell Blue Cross insurance policies, premiums must be kept as low as possible, and yet premiums are based on hospital operating costs. While costs have indeed been rising, in line with the continued improvement in the content and quality of hospital service, the Blue Cross program in recent years has exerted moderate pressure toward economy and efficiency in hospital operation.

It is true that some observers doubt if paying agencies are doing enough to induce economical operation of hospitals. It is even claimed that prepayment has led to extravagance. The challenge of the State insurance commissioners has been mentioned. Representatives of organized workers, who make up a large proportion of the Blue Cross membership, have been skeptical of the efficiency of hospital administration. In any case, public pressure created by a vast extension of prepayment for hospital care is doing much to bring hospitals together to explore common problems of effective administration.

One expression of this is the organization of joint purchasing arrangements. While the development is still modest, in some large cities hospitals have agreed on standard specifications for linens, laundry supplies, antiseptics, certain drugs, and the like, and have achieved lower prices through mass purchasing. The Hospital Bureau of Standards and Supplies, Inc., is a national organization devoted to this purpose. A nonprofit organization, it purchases many commodities for its hundreds of members, does product testing, and issues informational bulletins. Similar group purchasing activities are conducted by the hospital councils in Rochester, N.Y., and Harrisburg,

Pa., by the Federation of Jewish Philanthropies of New York City, and by others. The purchases made in this way, however, usually constitute only a small percentage of the total made by the cooperating hospitals (11).

Another measure of cooperation is the pooling of resources for educating nurses. Certain types of didactic instruction are given to the student nurses of one hospital in the training school of another. Students from many general hospital schools of nursing may receive practical training in mental disease, pediatrics, or obstetrics in "affiliated" hospitals specializing in these fields. In Saskatchewan, Canada, in Massachusetts, and elsewhere, centralized lectures for students from many nursing schools have been given in universities.

Medical schools have taken the initiative in a number of places to promote postgraduate education of physicians through the local hospitals in a region. Programs around the medical schools at Buffalo, Richmond, New Orleans, and Berkeley have been outstanding. Rotation of interns and medical residents from a university hospital among several surrounding community hospitals is a growing practice which helps elevate the quality of service in the smaller institution while it gives the young physician insight and experience in a simple grassroots setting (12).

Regional and metropolitan hospital councils with full-time staffs in the United States have increased from the first one at Rochester, N.Y., in 1945 to 23 in 1958 (13). Their functions vary greatly, but they all represent a pooling of interests by several institutions to achieve improvement in hospital service. The majority of the councils have been organized in large metropolitan cities, where a dozen or more hospitals are found. Their scope of activity changes from year to year, but there has been a clear tendency to progress from an original primary concern with construction planning to the wider problems of the content of hospital service.

Even so, hospital council activities are still oriented more to administrative problems than to elements of direct patient care (14). Programs depend on council members and their needs of the moment. While the Syracuse council, for example, regularly summarizes

vital statistics for hospitals of the region, it also does many one-time jobs, such as preparing a booklet to recruit young people for work in the hospital field. The Buffalo council supplies a clearinghouse for employment. The Philadelphia council does much to encourage uniform accounting procedures. The Harrisburg council is now deeply involved with reorganizing activity to comply with the Pennsylvania Insurance Commissioner's ruling of 1958 (1). The Chicago council is making arrangements with the telephone company and the many local fire and police departments for coordinated hospital action in the event of disaster. The Swift Current council in Saskatchewan provides consultant services in X-ray technology, pharmacy, dietetics, and accounting to its member hospitals (15).

Thus, hospital councils are in a stage of vigorous growth. Aside from their basic services, they are laying the groundwork for greater cooperation among sovereign hospitals in the future.

Evolution of interhospital cooperation to the point of unified management of several institutions has occurred only in a handful of places in the United States. Federal hospital systems for veterans, Indians, merchant marines, and similar groups under the Veterans Administration, Public Health Service, and other agencies, are, of course, highly rational. These programs, however, started out on a centrally organized basis under uniform rules and regulations. They do not include community hospitals open to all persons.

The closest thing to regional management of a network of community hospitals is seen in the Miners Memorial Hospital Association of the United Mine Workers of America. Supported by the welfare and retirement fund of this union of coal miners, the association operates 10 hospitals in the Appalachian Mountain States. There are regional and peripheral hospitals in the system. Authority is centralized with a branching-out of delegated responsibilities. Functions involving direct patient care are, of course, locally based, while supportive activities, such as accounting and payroll, specialized plant maintenance, purchasing, and staff hiring are done regionally for the entire group. Financial functions are centralized to

an even further degree; they are performed with electronic equipment at the United Mine Workers headquarters in Washington, D.C. (16).

In the Adirondack section of New York, there is a group of three small hospitals, set up by the Noble Foundation, under single management. Some church missions operate a network of small hospitals in the southwestern United States. In western Pennsylvania, the hospital division of Grenoble Hotels, Inc., is a private organization engaged in the business management of 11 general hospitals under voluntary auspices. Five independent hospitals in Newark, N.J., have just consolidated their administration as the United Hospital Association.

The Commonwealth of Puerto Rico, with the support of the Rockefeller Foundation and the Public Health Service, is developing a regional hospital system under central direction. A large regional center, 3 district hospitals, and about 14 small community hospitals are in the network. Not only is the management of all these hospitals unified, but even medical services throughout the region are supplied or directed by a staff of qualified specialists located at the regional center (17).

Discussion

This, then, is a brief review of where we stand in the United States in the broad range of hospital regionalization activities. A great deal is going on and established ideas of hospital services are obviously in ferment. Yet the surface of the possibilities of regionalized hospital services through teamwork in natural trading regions has hardly been scratched.

The chief determinants of the degree of interhospital cooperation are philosophical and technical. The philosophical or ideological determinants are found, of course, in our whole system of free enterprise in health service. They include the existence of two types of sovereignty: the autonomy of the boards of directors of voluntary hospitals and the independence of the practicing physicians who staff the hospitals.

We have seen how small bits of these sovereignties have been yielded through increased

cooperative activities among hospitals. Professional independence also has been modified by the widening group discipline within the medical staff organization in hospitals. Appointment of full-time chiefs of clinical services, centralized medical audit procedures, diligent tissue committees, and limitations of privileges have all helped to introduce a collective conscience into the practice of medicine in hospitals.

These two levels of sovereignty are central features of American health service, and they will doubtless be part of our life for a long time. Yet we are finding that cooperation and teamwork among hospitals does not reduce the dignity of the individual patient, doctor, board member, or administrator.

It is, however, the second determinant of any interhospital cooperation, the technical aspects, that will ultimately be most decisive. How much is really to be gained in effective hospital service by more highly organized relationships among institutions in a region? How much can the quality of care be improved by joint action and how much can costs be reduced?

To answer these large questions, they must be broken into many smaller parts. There are perhaps 15 to 20 principal activities involved in hospital service: nursing care, laboratory service, dietetics, business management, and plant maintenance, to name only a few. Under each of these are dozens or even hundreds of subdivisions. The activities in a laboratory service, for example, include the establishment and maintenance of equipment, the supervision and judgment exercised by a pathologist or laboratory director, the training of technicians of many types, the procedures for doing hundreds of tests, the review of technical performance to assure accuracy, the issuance of reports, and the like. Certain laboratory examinations, moreover, are very complex and can be done only in highly technical centers, while others are simple and can be done in the most modest setup.

If the advantages of regional cooperation are to be evaluated, each of these many units of hospital service must be considered objectively. Measurements must be made in which cost is one dimension and patient need another. Under the latter, one must consider the frequency of

need for a specific service and the importance of time. A corollary of time is distance and the feasibility of transportation.

These questions are familiar in other contexts, especially in the organization of industry. They are the bread-and-butter problems of students of production and industrial engineering. Are there secrets in American technology which have not been applied to the production and distribution of health services?

There is need to take a closer look at the organization of hospital services in geographic regions from the viewpoint of technical effectiveness. One must not overlook the patient, because his welfare must always remain in the center of the picture. One must likewise not lose sight of ideological realities in American culture. But research focused on the technical aspects of hospital regionalization is urgently needed to evaluate properly the advantages to be gained through cooperative efforts.

If clear-cut technical advantages to specific forms of teamwork among hospitals can be shown, half the battle will be won. To the extent that gains are demonstrable, the American mind usually finds ways of application. If more highly developed expressions of hospital regionalization can be shown to yield better hospital services at the same or lower costs than prevail in the United States today, we are bound to find ways of implementing these approaches which will be philosophically acceptable and consistent with our social values.

Career Opportunities

Columbia University School of Public Health and Administrative Medicine has announced an institute on new developments in psychiatry to be held November 18-19 in Syracuse, December 2-3 in Albany, and December 16-17 in New York City this year. Enrollment is open to personnel in national, State, and local health departments, in voluntary health agencies, and in family service organizations. Information may be obtained by writing to Program of Continuation Education in Public Health, 600 West 168th Street, New York 32, N.Y.

The University of Michigan and the University of Minnesota Schools of Public Health will hold an institute on prevention and management of handicapping conditions in infancy and childhood. November 16-20, 1959, in Ann Arbor, Mich., sponsored by Michigan

and Minnesota State maternal and child health and crippled children's programs under a grant from the U.S. Children's Bureau. Seminars and discussions on extent and distribution, pathogenesis, prevention, recent advances in management, and program planning and evaluation are a part of the program. Eligibility is limited to staff members in States in Regions V and VI of the U.S. Department of Health, Education, and Welfare. Further information may be obtained from Dr. Donald C. Smith, associate professor of maternal and child health, University of Michigan School of Public Health, Ann Arbor, Mich., for Region V, and Dr. Helen M. Wallace, professor of maternal and child health, University of Minnesota School of Public Health, Minneapolis, Minn., for Region VI.

Meals-on-Wheels Projects

MEALS-ON-WHEELS, a practical answer to the problem of feeding care for the aged and handicapped, has been adopted as a health service by a number of communities. These projects recognize that malnutrition is one of the chief causes of illness in the elderly person. Improvement in diet often results in recovery from physical disability.

The meals-on-wheels project in Columbus, Ohio, began in 1956 with voluntary contributions collected by the Columbus Federation of Women's Clubs. At that time, an estimated 400 persons in the city more than 65 years of age could not prepare nourishing meals for themselves.

So that no one would be denied the service because of inability to pay the entire cost, a sliding scale based on income was applied to determine the amount to be paid by the client.

Three plans were used to determine what recipients were to pay for the service. In plan A, public assistance recipients pay up to 80 cents daily, and other needy persons pay some portion of the cost. Under plan B, nonindigent, elderly, or handicapped recipients pay \$2 daily. In plan C, hospital patients returning to their homes who need the service temporarily until recovery pay \$2 daily unless they qualify under plan A.

The menu was planned by a member of the Columbus Dietetic Association. The meals, prepared and packaged by a quality restaurant, consist of a dinner of meat, fish, or poultry, a vegetable, salad, bread, butter, dessert, and milk; a supper of a sandwich, milk, and fruit; and a snack of fruit or juices with a sweet roll or ready-to-eat cereal. Weekday deliveries are made by four taxicabs with separate routes.

From April 1957 to January 1958, 742 meals under the payment plan of \$2 per day, and 1,922 meals under the payment plan of 80 cents per day were served to recipients.

Hospital patients were referred 1 day or more in advance by the physician or social service of

the hospital. The recipients ranged from 45 to 94 years of age; 15 were over 70 years of age; and 9 were over 80.

Most of the recipients were receiving regular medical attention. Four persons were receiving regular services of a visiting nurse. Most lived alone in a single room. While a few had adequate cooking facilities, they lacked the physical ability to use them.

The staff donating voluntary services was composed of a full-time director; a bookkeeper (half day a week); three investigators, a collector, and two nutritionists (4 hours a week each); four drivers for Sunday and holiday delivery and two casework supervisors (3 hours a week each); and 12 committee workers for publicity (2 days a month).

The meals-on-wheels project in Rochester, N.Y., providing food for "shut-ins" over 45 years of age has been in operation for more than a year.

The project, begun April 16, 1958, is administered by the Visiting Nurse Service of Rochester and Monroe County on a contract basis for the bureau of chronic diseases and geriatrics of the New York State Department of Health. It is a 3-year pilot study of one type of community health service, domiciliary feeding of the aged, to enable them to live independently.

At the end of the project, a manual based on the study will be prepared to assist other communities in setting up similar projects. Part of the pilot plan is the evaluation of the service with respect to nutrition, cost of operation, administration, medical problems, satisfaction of community needs, and technical aspects of preparation, packaging, and delivery of food.

Within an hour at midday, 5 days a week, 5 private automobiles, each manned by 2 volunteers, deliver and serve food for 2 meals to approximately 8 to 10 clients, a total of 40-50 persons served daily. The meals, a hot dinner and a cold high-protein sandwich supper, are

prepared and packaged at the specially equipped kitchen which VNS added to its headquarters in the heart of Rochester. Menus are planned by the staff nutritionist of the Visiting Nurse Service, and special diets, such as low-sodium and diabetic, are provided on physicians' orders.

The charges range from 50 cents to \$1.25 per day, with the "adjusted fee" scaled to income. Charges are payable in advance by the month on a signed agreement basis between the client and the association. It is a business-like, dignified arrangement, and appears to be acceptable to the clients.

The maximum number that can be served at the present time with the association's staff, equipment, and geographic and traffic limitations is about 50 persons. The project is generally working at capacity, although the number of clients varies. Because of basic requirements and effective screening prior to service by the public health nurse, the large

number of applicants thins out to a small number of eligibles. The association has been able to care for all who are approved.

The first annual report shows that the clients numbered 143 and ranged in age from 45 to 96 years, with an average age of 76.5 years. There were $2\frac{1}{2}$ times more women than men. Ten couples were served.

The number of days' service per client ranged from 1 to 253 days; the average was 58.2. All paid something more than 70 percent of the full fee. There were 91 regular diets and 52 special, on doctors' written prescriptions. Medical care was provided by private physicians to 115 of the 143. Relatives referred about 28 percent; the rest were referred by physicians, hospitals, social agencies, or the clients themselves.

The Rochester Visiting Nurse Service has played host to many visitors and observers, including public health workers attending a New York State health conference.

Diabetes Casefinding in the Virgin Islands

A diabetes casefinding campaign, combined with venereal disease testing, was conducted in the Virgin Islands in the spring of 1959 by the Islands' department of health assisted by the Public Health Service. Lasting from March through June, the islandwide screening program offered diabetes blood tests to an estimated 10,000 to 15,000 out of the total population of 24,000.

This was the first time mass screening for diabetes was done in the Islands of St. Croix, St. John, and St. Thomas. Besides discovering hitherto unknown diabetics and bringing them to treatment, the campaign will supply data on the prevalence of the disease in the Islands. These data are currently being processed.

Blood tests were offered all persons over 15 years of age, but special appeals were

made to persons most likely to have diabetes, such as relatives of diabetics, parents of babies of large birth weight, the obese, and adults over 40 years old. Public cooperation was stimulated by newspaper stories, flyers, radio broadcasts, and, via sound trucks, talks on the disease and its disabling effects if untreated.

Screening was carried out at fairs and other public gathering places. Industrial workers were tested during working hours and health department workers made door-to-door home visits to accommodate those desiring the test. The Hewson Clinitron, designed to perform the Wilkerson-Heftmann blood sugar screening test, was used in the program. At capacity the machine can complete 120 tests per hour.

Asian Influenza in High School Students

KENNETH D. ROGERS, M.D., and HORACE M. GEZON, M.D.

IN THE FALL of 1957 throughout Allegheny County, Pa., there was a sudden rise in the prevalence of acute respiratory infections accompanied by systemic symptoms and signs. Because of the forewarning that the Asian variant of influenza type A was likely to become epidemic and because the symptomatology of the prevailing illness was consistent with that of influenza, many of the cases were diagnosed clinically as Asian influenza.

However, as in any epidemic the question arose as to whether all of the acute illnesses had a common etiology or whether several types of illness were concurrent. In this particular epidemic, it was of interest to know which children had not been infected so that susceptibles could be immunized when supplies of vaccine became available. Information concerning attack rate in this population was also desired for estimating the likelihood of a second epidemic later in the year.

During the epidemic there was a high rate of absenteeism in the high schools of the county. A large number of students in several high schools answered a questionnaire concerning characteristics of any illness they had experienced during this period, and many of these students were studied serologically for the pres-

ence of specific antibody against the Asian variant of influenza type A. During the same time period, virus isolations were made in the Allegheny County Health Department laboratory from throat washings and autopsy specimens obtained from patients with acute respiratory disease. Finally, in an attempt to determine if the disease spectrum observed during the epidemic was unique, a repeat questionnaire survey of illness was made in one high school in the fall of 1958.

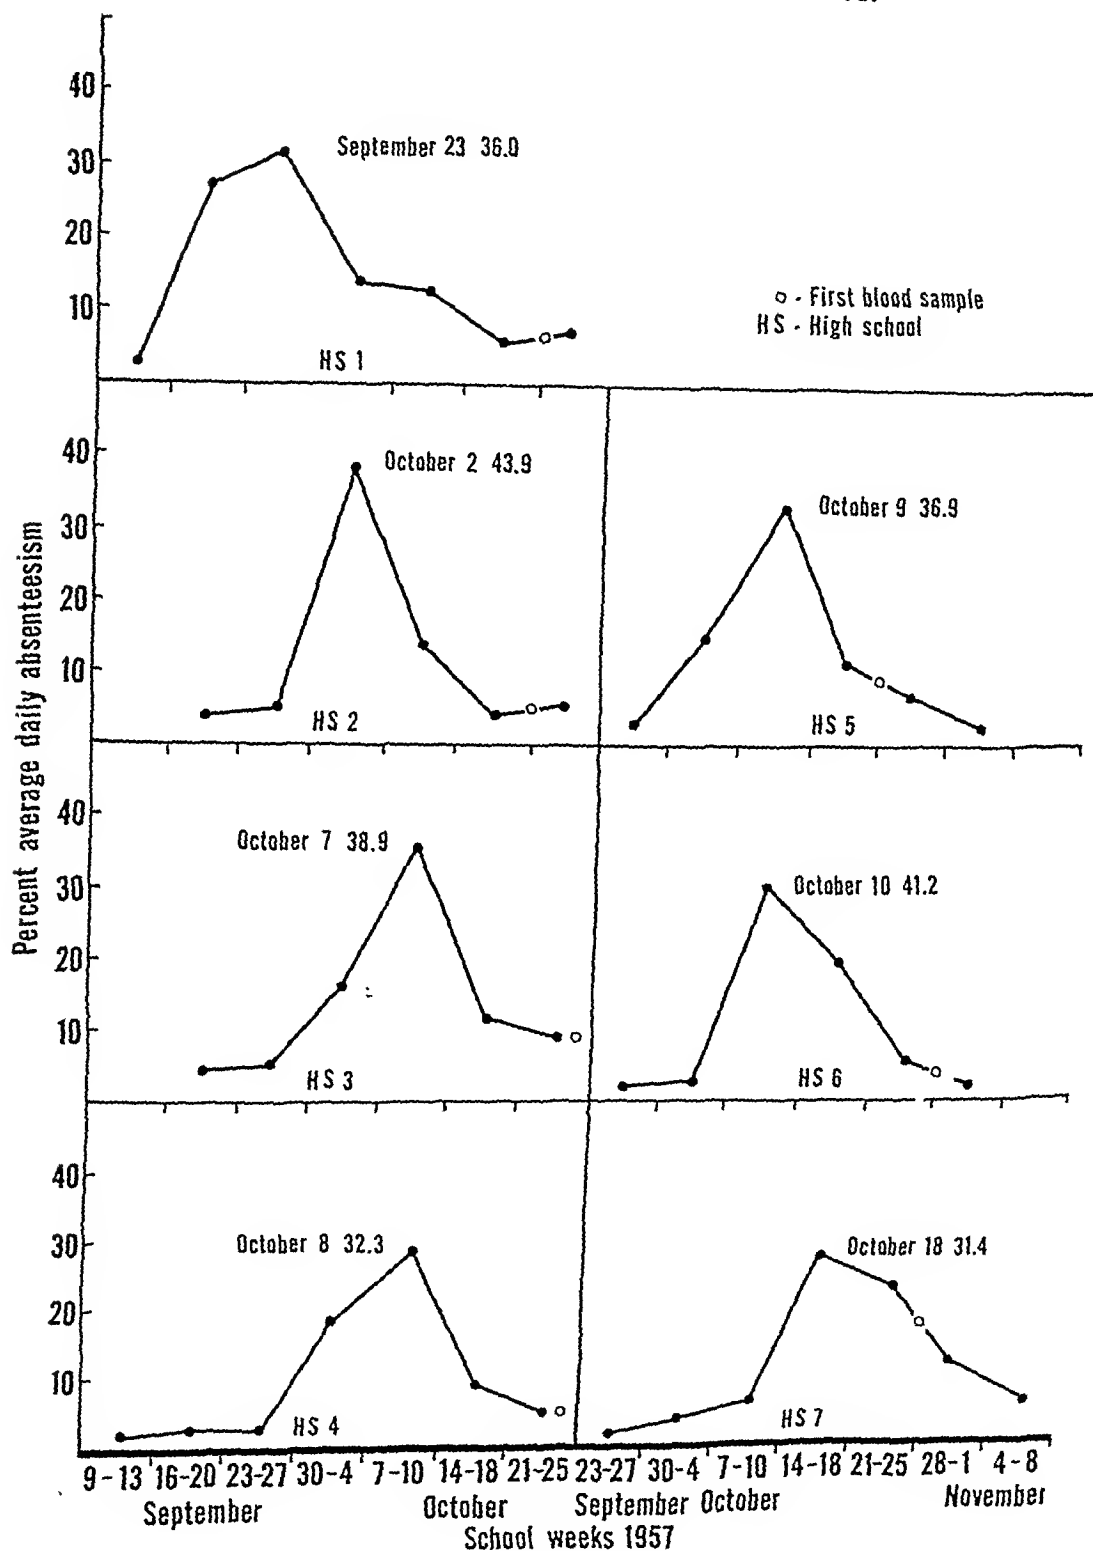

Blood Samples and Illness History

A total of 953 students in seven high schools distributed over the five county health districts were studied. In six of the schools samples were small in number and not selected in such a way as to make them representative of the whole school populations from which they were taken. In the remaining one, Dormont High School, the entire enrollment of 679 students answered questions concerning illness, and 429, or 63 percent, contributed blood samples. Therefore, most of the observations in this study were made on the Dormont school population.

From 10 to 31 days following the peak of absenteeism in each school, student volunteers gave blood samples and, at the same time, answered a simple questionnaire about incidence, duration, and symptomatology of any illnesses experienced in the preceding 30 days. Symptomatology was reported by both the student's written description of illness and a simple checklist of signs and symptoms likely to be present in illnesses of the gastrointestinal, respiratory, or central nervous systems. One year after the first illness history was obtained, the Dormont students were questioned concern-

Dr. Rogers is associate professor of maternal and child health, and Dr. Gezon, professor of epidemiology and microbiology, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, Pa. The study, partially financed by grants from the Pennsylvania Department of Health and the Children's Bureau, Department of Health, Education, and Welfare, was carried out with the cooperation of the Allegheny County Health Department.

Figure 1. Average daily absenteeism by percentage of enrollment in selected high schools, Allegheny County, Pa., September–November 1957

ing illness during the preceding nonepidemic month, September 24–October 24, 1958.

Fourteen to 24 days after the initial blood samples were obtained, additional samples were given by part of the original group. Dormont students who gave blood specimens a second time were chosen in approximately equal numbers according to the time and type of their experience during the epidemic period—not ill, ill and absent at the beginning of the period, ill and absent toward the end of the period, and ill but not absent. Second specimens were obtained from volunteers in other high schools without reference to their previous history.

Laboratory Materials and Methods

Serums. The serum was separated from whole blood on the day the specimen was obtained and stored in rubber-stoppered glass tubes at -10°C . The serum was thawed, diluted 1:20, and inactivated at 56°C . for 30 minutes just prior to testing. Paired serum specimens were tested at the same time. Single serum specimens were tested in large groups with appropriate positive and negative serum controls.

Complement fixation (CF) test. A modification of the standard Kolmer technique was used to detect antibodies against virus of Asian variant influenza type A. The antigen was prepared from pooled chorioallantoic (CA) and amniotic (A) fluid of infected embryonated eggs. Influenza virus A/Asian/Japan/305/57 which had been passaged four times in eggs, once in ferrets, three times in mice, and eight times in eggs was furnished by Dr. Keith E. Jensen. Ten- to 11-day embryonated eggs were inoculated amniotically, harvested after 48 hours incubation at 37°C ., and the CA and A fluids tested separately for hemagglutination using human type O cells. Fluids with a titer of 1:64 or greater were pooled, inactivated at 65°C . for 1 hour, and used as the antigen. Two units of antigen, as determined by titration against positive human serum, were employed. Twofold serial dilutions of serum from 1:20 to 1:320 were tested.

The final test contained 0.2 ml. serum, 0.2 ml. antigen, and 0.2 ml. of guinea pig complement containing two exact units. The tubes were incubated at 37°C . for 75 minutes, and imme-

diately afterwards 0.4 ml. of 2 percent sheep red blood cells sensitized with two units of rabbit hemolysin was added. The results were read after incubation for 20 minutes at 37°C . Comparative studies with incubation at 37°C . for 20 minutes and at 4°C . for 18 hours showed greater specificity with the former but greater sensitivity with the latter.

Virus isolations. Specimens were stored in sealed ampules at -70°C . until tested. Lung tissues were ground with sterile aluminum and prepared as a 10 percent suspension in nutrient broth containing 250 $\mu\text{g./ml.}$ penicillin and 250 $\mu\text{g./ml.}$ streptomycin. Nose and throat swabs in tryptose phosphate broth (Difco) were first plated on sheep's blood agar. Penicillin and streptomycin were then added and the broth inoculated amniotically into five 10- to 11-day embryonated eggs. Eggs were harvested after 48 hours incubation at 37°C . and CA and A fluids tested for hemagglutination. Specimens giving a negative reaction were passaged again in eggs and those giving positive reactions identified with the antisera to the influenza strains, A/Denver/1/57, B/GL/1739/54, and A/Asian/Japan/305/57.

Pattern of Spread

In six of the seven schools children answered questions regarding the presence and characteristics of illnesses occurring in the preceding month. Although there was a variation in the several schools, the relative order of frequency of various signs and symptoms was similar. For example, fever, headache, and sore throat were commonly reported, while diarrhea was infrequently reported. Because of the common clinical characteristics, it was considered likely that the same epidemic disease was present in the various schools.

The pattern of absenteeism in the seven high schools was also similar. All showed an abrupt rise in absence rates reaching a peak of 30 to 40 percent of the enrollment within 7 to 10 days and returning to near normal levels by the third week of the epidemic. Schools 3, 4, 5, and 6, which were in widely separated parts of the county, had the time of maximum absence October 7 to 10 (fig. 1). The peak absence dates for the other three schools preceded or followed this period by 1 or 2 weeks.

The pattern of spread within Dormont (HS 4) was examined in detail. It was assumed that students within a given grade were more intimately in contact with one another and that if the epidemic within the school had started first in a small group, such a pattern of spread might be detected by studying absence by grade and time. The daily incidence rate of absence by grade during the period of the epidemic showed no evidence of differences in time, except possibly in the more explosive development of disease in the ninth grade (fig. 2).

Severity of Illness

In Dormont High School, severity of illness in children of different ages was estimated from the relationship between absence and illness. Illness which was accompanied by absence from school was assumed to indicate greater severity than illness without absence. The students, by grades, were classified into three categories according to illness-absence experience during the period September 24 to October 24,

1957. The pattern was similar in all four grades.

Grade	Ill and absent (percent)	Ill, not absent (percent)	Neither ill nor absent (percent)
9-----	72	10	17
10-----	75	7	19
11-----	76	8	14
12-----	72	11	17
All students-----	74	8	18

Illness Characteristics by Time Periods

To determine if the illness exhibited by Dormont students changed in characteristics during the period of greatest absence frequency, students who volunteered to give blood specimens were divided into three subgroups according to the week in which their first day of absence occurred. The frequency of symptoms and signs reported was similar for the three groups although it tended to be lower in the last time period (table 1). The duration of individual absence was similar for the first two periods but tended to be shorter in the last. Since data were collected the day following

Figure 2. Daily incidence rate of absence by week in students by grade, Dormont High School, September–October 1957 and 1958

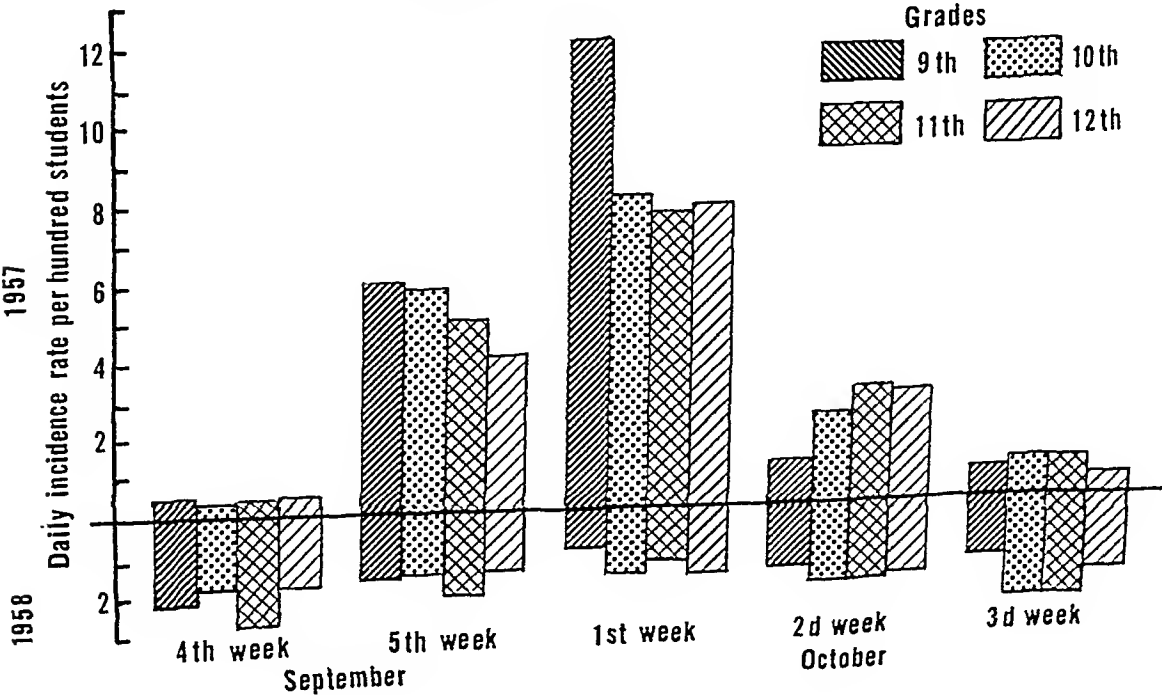

Table 1. Percent frequency of signs and symptoms in 300 students¹ of Dormont High School by week of onset of illness, September–October 1957

Sign or symptom	Onset of illness		
	Sept. 30–Oct. 6 (N=109)	Oct. 7–13 (N=141)	Oct. 14–23 (N=50)
Cough.....	80	85	72
Fever.....	81	80	66
Headache.....	71	77	70
Sore throat.....	67	72	52
Running nose.....	60	70	58
Weakness.....	58	55	42
Body aches.....	61	40	46
Chills.....	49	45	44
Dizziness.....	39	30	28

Diarrhea.....	2	6	6
Days absent:			
3 days or less.....	49	51	78
4 days or more.....	51	49	22

¹ Includes only ill students in volunteer group.

the end of the last time period, observations were not available on students still absent because of illness. Because of persisting absence these students might have been expected to have a large number of symptoms and signs to report and to have longer illnesses.

Serologic Studies, 1957

Approximately two-thirds of the Dormont pupils volunteered to give blood samples in the 1957 study. The rate of volunteering was equal for girls and boys (69 percent and 68 percent, respectively). Girls in all grades volunteered at approximately the same rate, but boys were more numerous in the 9th and 10th grades (80 percent) than in the 11th and 12th grades (53 percent). Participation by classrooms varied from 52 to 89 percent. The lowest rate of volunteering was in one sophomore classroom; only 47 percent of the girls volunteered to give blood samples.

To determine the degree to which the volunteers were typical of the entire high school population, they were compared with the non-volunteering students in respect to rate of ab-

sence and characteristics and severity of illness experienced in the preceding month. The frequencies of specific signs and symptoms are similar in the two groups (table 2). The rates of absence and illness were also similar for the two groups. The close agreement in illness experience in the two groups indicates that the students volunteering to give blood specimens were representative of the whole school population.

Student	Ill and absent (percent)	Ill, not absent (percent)	Neither ill nor absent (percent)
Volunteer	74	9	17
Nonvolunteer	75	6	19

The association was determined between levels of influenza CF antibody and various aspects of illness experience in the 429 Dormont volunteers. There was a consistent tendency for students with higher antibody titers to report various signs and symptoms more frequently. The frequency of symptoms as well as illnesses was markedly diminished in those without detectable antibody (table 3). Similarly, in the other six schools, children without measurable antibodies (titers less than 1:20) were less often ill during the preceding month or, when ill, had fewer signs and symptoms than children with detectable levels of antibody.

Only 23 Dormont students reported receiving influenza vaccinations sometime in the 6 weeks

Table 2. Symptomatology of volunteers and nonvolunteers in Dormont High School ill during September–October 1957

The pattern of spread within Dormont (HS 4) was examined in detail. It was assumed that students within a given grade were more intimately in contact with one another and that if the epidemic within the school had started first in a small group, such a pattern of spread might be detected by studying absence by grade and time. The daily incidence rate of absence by grade during the period of the epidemic showed no evidence of differences in time, except possibly in the more explosive development of disease in the ninth grade (fig. 2).

1957. The pattern was similar in all four grades.

Grade	Ill and absent (percent)	Ill, not absent (percent)	Neither ill nor absent (percent)
9-----	72	10	17
10-----	75	7	19
11-----	76	8	14
12-----	72	11	17
All students-----	74	8	18

Illness Characteristics by Time Periods

To determine if the illness exhibited by Dormont students changed in characteristics during the period of greatest absence frequency, students who volunteered to give blood specimens were divided into three subgroups according to the week in which their first day of absence occurred. The frequency of symptoms and signs reported was similar for the three groups although it tended to be lower in the last time period (table 1). The duration of individual absence was similar for the first two periods but tended to be shorter in the last. Since data were collected the day following

Severity of Illness

In Dormont High School, severity of illness in children of different ages was estimated from the relationship between absence and illness. Illness which was accompanied by absence from school was assumed to indicate greater severity than illness without absence. The students, by grades, were classified into three categories according to illness-absence experience during the period September 24 to October 24,

Figure 2. Daily incidence rate of absence by week in students by grade, Dormont High School, September-October 1957 and 1958

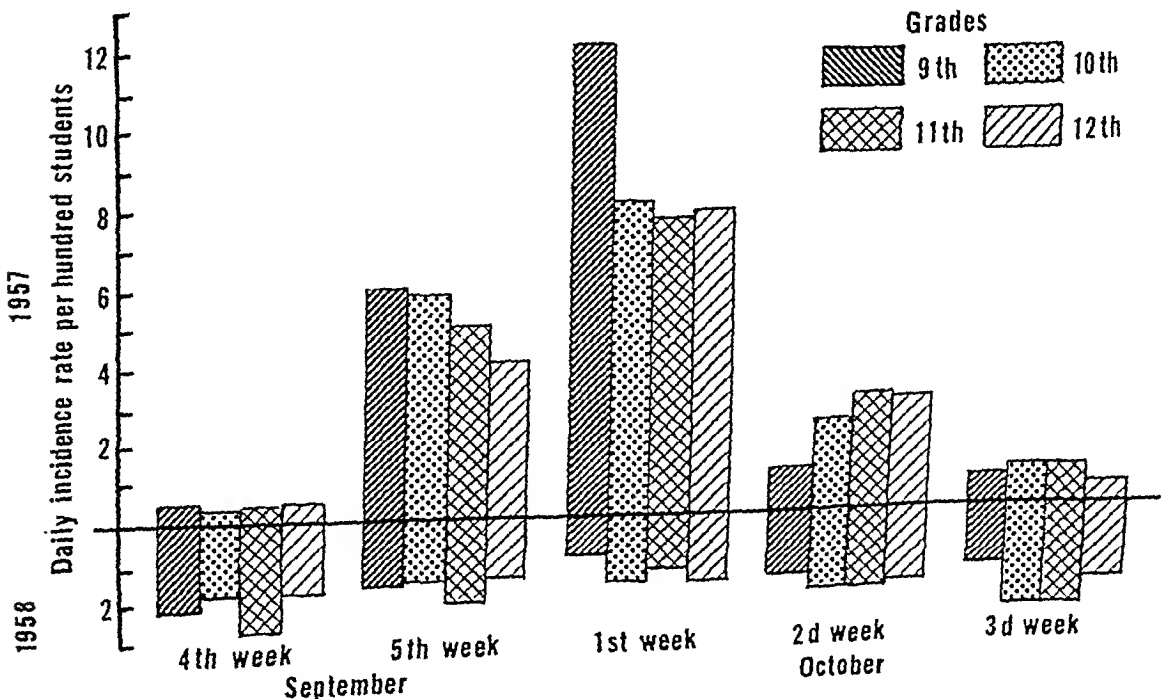

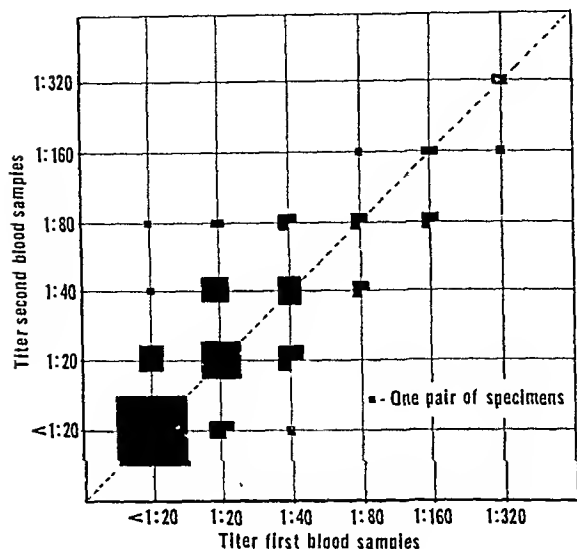

Figure 3. Relationship of first and second influenza CF antibody titers in 175 students, Allegheny County, Pa., October–November 1957

versely, of those with illness late in the epidemic, more had rising than falling titers. However, the magnitude of most of these rises and falls was only twofold, and only 7 percent of patients previously negative became positive by the time the second specimens were obtained. The constancy of antibody level in successive samples suggests that presence of antibody was not a transient phenomenon likely to be missed by variations in the time of sampling. Therefore, the absence of antibody with the influenza syndromes can not be explained on the basis of the time the specimens were obtained.

Second blood samples, obtained from an additional 79 students in two other high schools, confirmed the close agreement between antibody levels on specimens obtained 3 to 4 weeks apart (fig. 3).

Hypothetical Influenza Syndromes

The signs and symptoms were ranked in order of frequency of occurrence in Dormont students exhibiting measurable antibody (table 3). This was assumed to constitute a measure of sensitivity of a particular symptom or sign as indicating influenza infection. However, certain of these were also noted with high frequency in children lacking antibody. Therefore, a measure of specificity was also de-

veloped and was expressed as the ratio of the frequencies with which given symptoms and signs occurred in the antibody present and undetectable groups. These ratios were ranked in order of magnitude. The sum of the rank order of sensitivity and the rank order of specificity was calculated. For example, cough was first in sensitivity and fourth in specificity, giving a sum of five. The signs and symptoms with the lowest sums of sensitivity-specificity ranks were presumed most likely to be characteristic of Asian influenza. These were cough, fever, headache, weakness, chills, and dizziness.

Using the results of these sensitivity-specificity ratings, three categories of illness were arbitrarily defined: (a) strict influenza syndrome which consisted of a history of absence from school with an illness having three or more of the following symptoms or signs: cough, fever, headache, weakness, chills, and dizziness; (b) modified influenza syndrome which consisted of an illness having three of the above symptoms or signs without absence or two of the symptoms and signs with absence; (c) other disease which consisted of any illness, regardless of absence, not fitting the strict or modified syndrome categories. The three groups were mutually exclusive.

When students were divided into these illness categories or grouped according to antibody titer, there appeared to be a gradient of illness involvement (moving from strict syndrome, to modified syndrome, to other disease, to no disease) which was directly associated with the height of antibody titers (fig. 4).

Comparison 1957, 1958

All 804 Dormont students again answered questions concerning the characteristics of illness experienced during September and October of 1958. These data were compared with data collected in 1957. Illness-absence experience for 1958 was classified by grade.

Grade	Ill and absent (percent)	Ill, not absent nor (percent)	Neither ill (percent)
9	23	9	68
10	24	11	65
11	27	6	67
12	22	5	73
All students	24	8	68

No illness.....	3	10	32	.2

¹ Titer 1:20 or greater. ² Titer less than 1:20. ³ Derived from fewer than 35 students.

preceding October 24, 1957. In this small group the proportion of those with present or undetectable antibody titers as well as the proportion of those experiencing illness in the September–October period paralleled that of the nonimmunized group. For this reason the effect of immunization was not considered in this study.

Duration of absence also varied in relation to CF antibody titers. Dormont students (including those without illness) with titers of 1:80 or greater against Asian influenza averaged 3.7 days absence; with titers of 1:40, 3.5 days; with titers of 1:20, 2.8 days; and with titers less than 1:20, 1.7 days.

While it was possible to identify certain symptoms and signs with the epidemic illness and to demonstrate that students exhibiting these were more likely to have detectable CF antibody, the association of history of illness and serologic evidence of infection was not absolute. Students ill and absent but without detectable antibodies and students with less severe illness not requiring absence had quantitatively rather than qualitatively different symptomatology from students with typical

illness and detectable antibody levels. Even with mild illness, symptoms and signs, although less frequent than with typical illness, were often those associated with influenza-like disease rather than with distinctly different disorders.

These observations were consistent with infection by a single rather than several agents. Individual variations in response to infection could have resulted from differing degrees of exposure to the agent, differing host thresholds for clinical symptoms and signs with infection, or from differing host ability to produce CF antibody following infection. The fact that children without a history of illness also gave evidence, in some cases, of CF antibody formation supports this interpretation.

Many students gave histories of illness typical of the epidemic disease during September and October 1957 but showed no demonstrable influenza CF antibody. One explanation for this observation would be that these students experienced illness so near to the time when blood samples were obtained that antibody rise had not yet taken place. Therefore, to test this hypothesis, second samples were obtained from 175 children 2 to 3 weeks later.

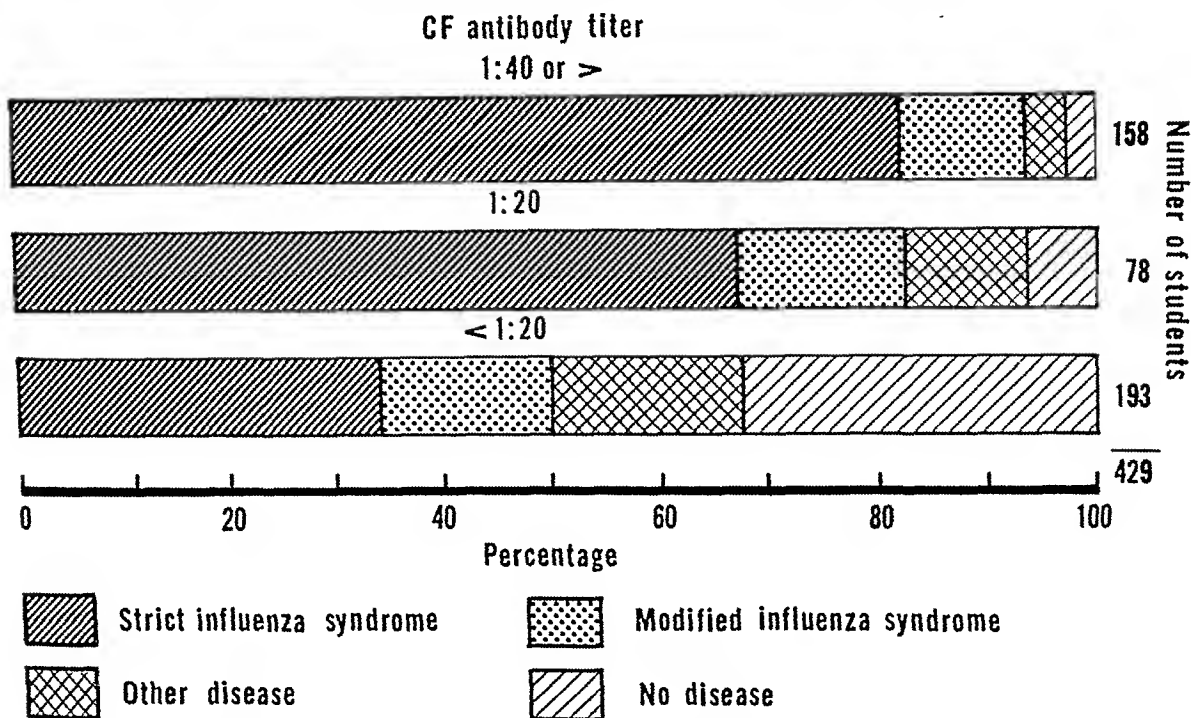

At Dormont, 96 donors of second blood samples were selected from the original volunteers according to their illness experience. The results in the various groups are given in table 4. Of those with illness early in the epidemic, only 3 percent had a rising titer, while approximately 20 percent had a falling titer. Con-

Table 4. Relationship of first and second influenza CF antibody levels in paired specimens from 96 students with varied illness experience, Dormont High School, 1957

week, and about 70 percent of the children were absent at some time during this period. Prevalence rates and length of absence (approximately 3.5 days) were similar for all grades. Attempts to isolate an influenza virus from throat swabs of 17 students in the first day of clinical illness were unsuccessful.

Clinical characteristics of the illnesses were studied to determine the possible etiological agent and the proportion of absence caused by the illnesses. The 1957–58 questionnaire concerning signs and symptoms of illness was given to 103 children returning from absence on March 16 and 17, 1959. Sixty percent of children had symptomatology compatible with the strict influenza syndrome previously described, 17 percent were classified as modified syndrome, and 23 percent as other disease. These figures were in close agreement with the symptomatology reported with Asian influenza in 1957 and markedly different from the experience in October 1958.

Because of the high prevalence of the characteristic influenza syndrome, the known high level of immunity to Asian influenza in this population, and the isolation during the same

time period of influenza type B in similar outbreaks in other parts of the United States, it was considered likely that most of the absence in Dormont High School from March 9 to 27, 1959, was due to influenza type B infection.

Virus Isolation

Starting in July 1957 throat swabs and washings for virus isolation from patients suspected

Figure 5. Gradient of illness involvement of Dormont High School students, September–October 1957 and 1958

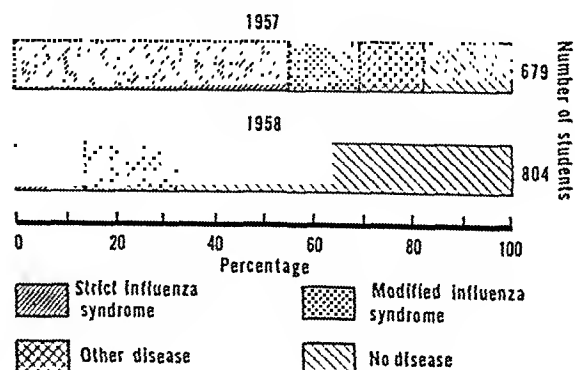

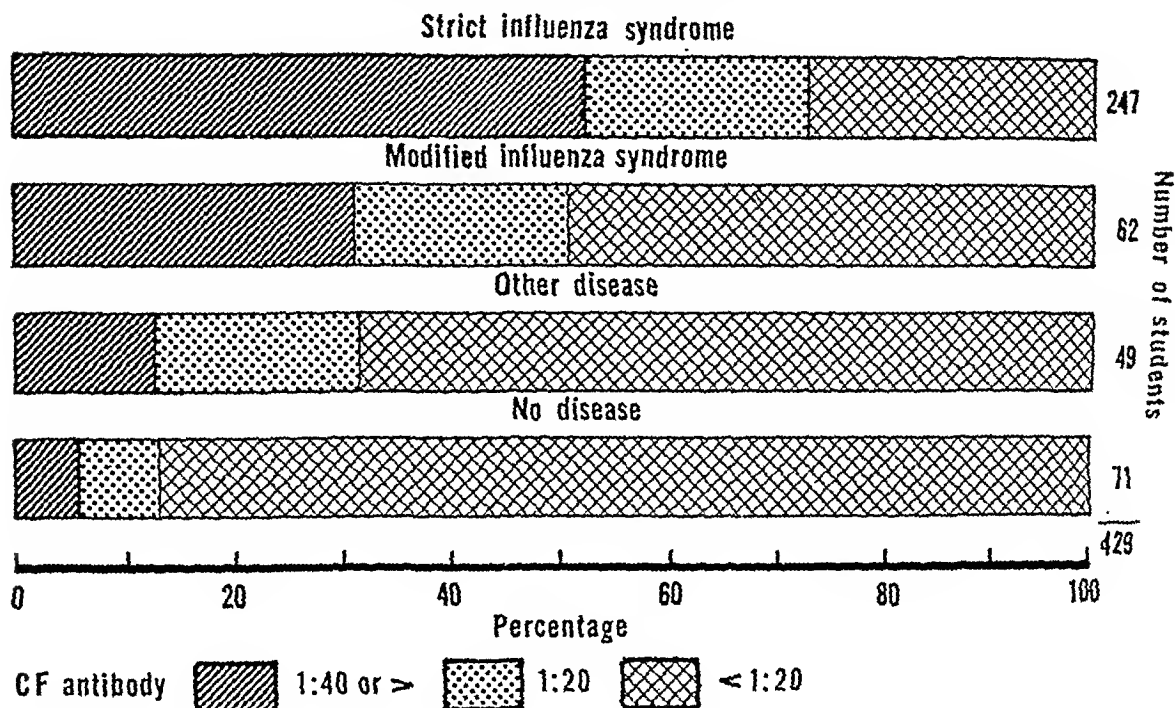

Figure 4. Relation of clinical gradient of illness involvement to level of influenza CF antibody, Dormont High School, September–October 1957

Again, there was no difference in the pattern by grade. However, when the 2 years were compared, there were approximately one-third as many in the category of ill and absent and approximately four times as many in the category neither ill nor absent in 1958 as in 1957.

When 1958 incidence rate of absence was plotted by grade (fig. 2), there was no variation by week or grade.

When symptoms and signs exhibited during illness were compared for the 2 years, students in 1957 not only reported almost twice as many symptoms and signs per illness, but certain specific signs and symptoms were much more frequently reported. Fever, weakness, chills, body aches, and pain behind the eyes were reported two and a half to more than three times as frequently in illnesses occurring in the epidemic year. On the other hand, the frequencies with which diarrhea, nausea or vomiting, and stomach ache were reported were essentially the same in both years.

Illnesses of 1958 were grouped according to the 1957 classification of strict and modified influenza syndromes, other disease, and no disease. The percentage of students falling into each

category differed markedly in the 2 years (fig. 5). Because of the great difference in the numbers of children with no disease between 1957 and 1958, only ill children were considered. It appears that the illnesses experienced in 1957 and 1958 differed markedly not only in attack rate but also in symptomatology.

Category	Percent ill children by category	
	1958	1957
Strict influenza syndrome.....	17.9	68.6
Modified influenza syndrome.....	25.3	17.7
Other disease.....	56.8	15.7

Spring 1959 illness

During March and April 1959 increased school absenteeism due to influenza-like illness was reported to the Public Health Service from 29 States and the District of Columbia. In 16 States and the District isolations of type B influenza were reported but they were few in number and made with difficulty.

Between March 9 and 27, 1959, absence in Dormont High School reached a peak of 23 percent of the enrollment during the second

but also development of serologic evidence of infection in asymptomatic subjects. Therefore, the minimum incidence of Asian influenza infection in the Dormont school was considered to be represented by the number of children exhibiting specific antibody or a history consistent with the influenza syndromes, or both. The incidence, thus determined, was 78 percent.

Since the antibody test identified few children who were not already identified by the clinical pattern of illness, but not vice versa, it was concluded that clinical history alone (presence of influenza syndromes) might constitute a satisfactory estimate of the incidence of Asian influenza infection. If such a clinical history index were also a valid measure of incidence of influenza infection due to other types, it would have the advantage of minimizing the need for laboratory studies. However, the syndrome derived from an epidemic experience is not necessarily applicable in non-epidemic years. In the fall of 1958 no isolations of influenza virus were made locally and essentially none was reported nationally. Yet, during this same period 5 percent of the population of Dormont High School demonstrated the strict influenza syndrome, and 7 percent, the modified influenza syndrome.

The method described in this study for establishing incidence of a specific infection during an epidemic might be applied to the study of other epidemic illnesses. The method consists of selecting the signs and symptoms reported most frequently with illnesses during an epidemic period (sensitivity); obtaining blood samples during the acute and convalescent stage (or in the convalescent stage only with a newly introduced agent) from a representative sample of the study population to determine antibody against the determined etiological agent; and calculating the signs and symptoms most frequently present in patients exhibiting changes in titer of specific antibody (specificity). By combining sensitivity and specificity indexes, a clinical syndrome may be

constructed for use in estimating incidence of specific illness in other groups during an epidemic.

Summary

The etiology of an epidemic of acute influenza-like illness in Allegheny County, Pa., in the fall of 1957 was investigated. High school students were questioned concerning symptomatology of any illnesses during this time period and CF tests against the Asian variant of influenza type A were done on blood samples from part of this group. The signs and symptoms reported most commonly with illness during this period (sensitivity) were combined with the signs and symptoms most frequently present in patients exhibiting changes in titer of specific antibody (specificity). The combined sensitivity-specificity index was used to construct a clinical syndrome considered appropriate for estimating incidence of specific illness during an epidemic period.

¹ No specimens.

of having influenza were received at the Allegheny County Health Department laboratory. As illness in the community increased and physicians became more aware of the diagnostic service available, more specimens were submitted. In the last quarter of the year lung tissue and bronchial secretions obtained at autopsy were also submitted. Asian variant type A influenza virus was isolated in 1957 only during September, October, and November. The data indicate that the highest percentage of virus isolation from specimens from all sources occurred during October when the population of the county was experiencing the peak of an epidemic (table 5).

Discussion

Both serologic and clinical indexes were used to estimate the incidence of infections caused by Asian variant influenza type A virus in the 1957 epidemic in Dormont High School. Since this virus was newly introduced into the United States during the summer and late fall of 1957, the percentage of persons showing antibody to it after an epidemic of influenza-like illness could be considered one index of group infection. In other populations studied after such an epidemic illness in the same year, specific antibodies (CF or hemagglutination inhibition) were reported in 35 to 75 percent of persons (with and without history of illness) from whom blood samples were obtained (1,

2). In Dormont High School specific antibody was exhibited by 55 percent of the total population studied and in 63 percent of those children ill during the epidemic.

The validity of using the clinical history as an index of influenza infection was based on the highly characteristic signs and symptoms occurring in previous influenza epidemics and reported in the 1957 influenza-like illnesses in various parts of the world (1, 3–6). These were fever, headache, cough, sore throat, fatigue or malaise, chills or chilliness, ocular pain, and bone, muscle, and joint ache. Nausea, diarrhea, abdominal pain, chest pain, and rash were almost always absent. In addition, these illnesses were characterized by sudden onset, high attack rate, moderate severity, short duration, and rare complication by secondary infection.

A majority of these symptoms was also evidenced in histories given by ill students in the Dormont school. Sixty-seven percent exhibited a strict influenza syndrome consisting of absence from school plus three or more of these signs and symptoms—fever, cough, headache, dizziness, chills, and weakness. Further evidence that this 1957 epidemic illness had distinct symptomatology was supplied by a study of illness characteristics during the same time period the following year. In 1958 only 18 percent of the ill children exhibited the strict influenza syndrome.

In the previously cited studies of Asian influenza infections in other populations, positive association between a clinical history of influenza-like illness and presence of specific antibody was reported. In Dormont High School this was also true. Sixty-seven percent of children with strict influenza syndrome had detectable levels of specific antibody as compared with 50 percent with the modified influenza syndrome, 31 percent with other illness, and 13 percent with no illness. However, the lack of association between presence of antibody and a history of influenza-like illness has also been reported previously in both natural and experimental infections. Bell and associates (7) artificially induced Asian influenza infections in volunteers and demonstrated not only variations in clinical response of different individuals given equal dosage of virus

Health Research Facilities Grants

Fifty-seven grants to help build and equip additional health research facilities were approved by the Public Health Service in August 1959 for 47 institutions in 23 States and the District of Columbia.

The grants, totaling \$11,235,480, are made on a matching-fund basis. They are authorized by the contingent resolution for fiscal year 1960 passed by the Congress on June 30, 1959, and are the first awards under the 3-year extension authorized by the 85th Congress during 1958. The extended program, like the initial one set up in 1956, has at its disposal \$30 million annually.

Administered by the National Institutes of Health, Public Health Service, the health research facilities construction program awards grants to both public and nonprofit hospitals, medical and dental schools, schools of public health, and other research institutions. The recipient institutions and facilities follow.

Animal Inhalation Exposure Chambers

Public Health Monograph No. 57

Exposure Chambers for Research in Animal Inhalation. By David A. Fraser, Ronald E. Bales, Morton Lippmann, and Herbert E. Stokinger. Public Health Monograph No. 57 (PHS Pub. No. 662), 54 pages, illustrated. U.S. Government Printing Office, Washington, D.C., 1959, price 40 cents.

The accompanying summary covers the principal contents of Public Health Monograph No. 57, published concurrently with this issue of *Public Health Reports*. The authors are with the Occupational Health Field Headquarters, Occupational Health Branch, Public Health Service.

For readers wishing the data in full, copies are on sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. Official agencies and others directly concerned may obtain single sample copies without charge from the Public Inquiries Branch, Office of Information, Public Health Service. Copies will be found also in the libraries of professional schools and the major universities and in selected public libraries.

The phenomenal increase in the amounts and kinds of chemicals used in industry, in the defense establishments, and in the home, with attendant concern about the potential health effects of community air pollution, has aroused a demand for toxicity information that can be gained only through carefully controlled studies of inhalation toxicology. New investigators entering the field often encounter a bewildering array of sizes and shapes of exposure chambers and accessory equipment, and are faced with the choice of either copying a chamber designed by a previous worker for a different set of conditions or developing their own design through a time-consuming series of trial and error experiments.

To help these investigators avoid some common difficulties and sources of error, the Occupational Health Branch of the Public Health Service has prepared a monograph on exposure chambers for research in animal inhalation, drawing on more than 40 years' experience with animal inhalation studies by investigators in its laboratories, as well as the experience of other research centers and private investigators.

The Occupational Health Field Headquarters laboratory currently uses four types of total-enclosure exposure chambers: large-scale, control, small-scale, and pilot. The features of each type that have proved of value in ease of operation and maintenance, in reliability of performance, and in adaptability are described in detail. Emphasis is placed on the fundamental requirements of the chambers and the reason for each particular design. Design considerations, such as size, shape, construction materials, maintenance, animal complement and placement, airflow requirements, heat balance, and air conditioning, are discussed.

Since the maintenance of a desired test atmosphere is the most important aspect of animal exposure chamber operation, attention is given to the various interdependent factors which influence this atmosphere. All test atmospheres fall into one of three general categories: dispersion of solid particulates in air, mist or dispersion of liquid droplets in air, and gas or vapor forming a single and homogeneous phase with air. These are dealt with in order of decreasing complexity and difficulty of producing and maintaining satisfactory performance in the chamber. Basic equations and formulas affecting particles and chamber dynamics are given and used to predict the performance of specific chambers.

Routine day-to-day operation of the chambers is described with suggestions for safety

Animal Inhalation Exposure Chambers

Public Health Monograph No. 57

Exposure Chambers for Research in Animal Inhalation. By David A. Fraser, Ronald E. Bales, Morton Lippmann, and Herbert E. Stokinger. Public Health Monograph No. 57 (PHS Pub. No. 662), 54 pages, illustrated. U.S. Government Printing Office, Washington, D.C., 1959, price 40 cents.

The accompanying summary covers the principal contents of Public Health Monograph No. 57, published concurrently with this issue of *Public Health Reports*. The authors are with the Occupational Health Field Headquarters, Occupational Health Branch, Public Health Service.

For readers wishing the data in full, copies are on sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. Official agencies and others directly concerned may obtain single sample copies without charge from the Public Inquiries Branch, Office of Information, Public Health Service. Copies will be found also in the libraries of professional schools and the major universities and in selected public libraries.

The phenomenal increase in the amounts and kinds of chemicals used in industry, in the defense establishments, and in the home, with attendant concern about the potential health effects of community air pollution, has aroused a demand for toxicity information that can be gained only through carefully controlled studies of inhalation toxicology. New investigators entering the field often encounter a bewildering array of sizes and shapes of exposure chambers and accessory equipment, and are faced with the choice of either copying a chamber designed by a previous worker for a different set of conditions or developing their own design through a time-consuming series of trial and error experiments.

To help these investigators avoid some common difficulties and sources of error, the Occupational Health Branch of the Public Health Service has prepared a monograph on exposure chambers for research in animal inhalation, drawing on more than 40 years' experience with animal inhalation studies by investigators in its laboratories, as well as the experience of other research centers and private investigators.

The Occupational Health Field Headquarters laboratory currently uses four types of total-enclosure exposure chambers: large-scale, control, small-scale, and pilot. The features of each type that have proved of value in ease of operation and maintenance, in reliability of performance, and in adaptability are described in detail. Emphasis is placed on the fundamental requirements of the chambers and the reason for each particular design. Design considerations, such as size, shape, construction materials, maintenance, animal complement and placement, airflow requirements, heat balance, and air conditioning, are discussed.

Since the maintenance of a desired test atmosphere is the most important aspect of animal exposure chamber operation, attention is given to the various interdependent factors which influence this atmosphere. All test atmospheres fall into one of three general categories: dispersion of solid particulates in air, mist or dispersion of liquid droplets in air, and gas or vapor forming a single and homogeneous phase with air. These are dealt with in order of decreasing complexity and difficulty of producing and maintaining satisfactory performance in the chamber. Basic equations and formulas affecting particles and chamber dynamics are given and used to predict the performance of specific chambers.

Routine day-to-day operation of the chambers is described with suggestions for safety

precautions and increased precision of operation through the use of automatic accessory equipment. Some of the forms and methods that are used by the laboratory for recording data can serve as a guide for newcomers in the field.

With an understanding of these fundamental concepts, the investigator should be able to modify any of the chambers described to meet

the requirements of his own experiment with a minimum of time and effort and little sacrifice of essential performance characteristics.

The monograph also includes a comprehensive and critical summary of the literature and history of animal inhalation exposure chambers from the first report in 1865 to the present. There are more than 80 references and 30 illustrations and tables.

Epidemiological Notes

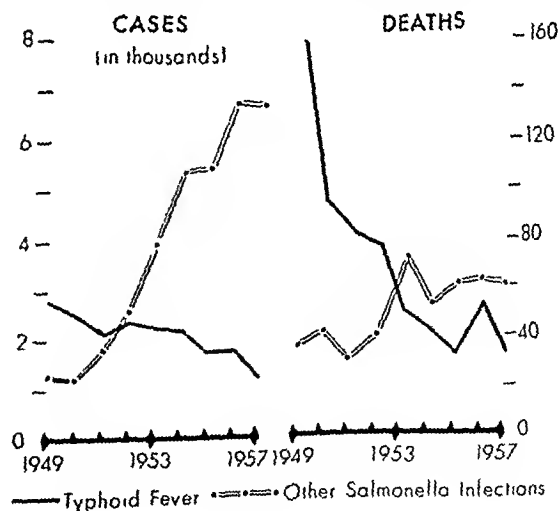

Salmonellosis

During the past decade, while typhoid fever has been reported less frequently and has caused fewer deaths from year to year, other *Salmonella* infections have shown the opposite trend. In 1950 twice as many cases and deaths from typhoid fever were recorded as for other *Salmonella* infections (see chart). In 1957, however, there were five times more cases of the latter than of typhoid fever, and the number of deaths was also in excess of those for typhoid fever. The increase in deaths has been more evident in young children and in persons over the age of 55 years.

The increase in number of reported cases of *Salmonella* infections, exclusive of typhoid fever, probably is due mainly to more complete notification which has followed greater awareness of these infections and an improvement in facilities for laboratory diagnosis. It also seems reasonable to assume that more frequent certification of deaths from these infections is due partly to such factors.

As typhoid fever has only one known reservoir of infection, man, its control is relatively simple. The other *Salmonella* infections are common to many species of animals, as well as man, and the disease can be transmitted not only by contact with infected animals and their excreta but also by consumption of the meat or other products of infected animals. The control of these infections is difficult because they are so widely distributed.—CARL C. DAUER, M.D., medical adviser, National Office of Vital Statistics, Public Health Service.

Numbers of cases and deaths from typhoid fever and other *Salmonella* infections, 1949-57

Federal Publications

Working Paper on Financing Migrant Health Services. *The President's Committee on Migratory Labor; June 1959; 67 pages.*

Methods either currently in use or proposed to finance health services for foreign, offshore, and domestic migratory farmworkers in the continental United States are discussed. A resource document based on the study initiated in May 1957, this paper also describes inherent problems of migratory laborers and emphasizes the need to provide them with year-round health insurance coverage.

A limited number of copies are available from the Division of Special Health Services, Public Health Service, or the President's Committee on Migratory Labor, Department of Labor, Washington 25, D.C.

Brucellosis in the U.S.S.R. A review of the literature. *PHS Publication No. 635; 1959; by Julian Hoptman; 77 pages; 30 cents.*

Designed to acquaint medical scientists with research activities and progress within the U.S.S.R., this monograph evaluates the investigations, related developments, and control of brucellosis in the Soviet Union.

Discussions of the history, epidemiology, clinical aspects, pathology and pathogenesis, biochemical studies, diagnosis, resistance and immunity, and therapy provide a description of brucellosis in man and veterinary problems pertaining to it.

Activities of the National Institutes of Health in the Field of Gerontology, January 1959. *PHS Publication No. 695; 1959; 121 pages.*

Intramural and extramural research and training projects on aging conducted by the National Institutes of Health are listed and briefly described.

Identified as being either primarily or secondarily related to

gerontology, the projects are classified according to major discipline. General, major multidisciplinary, and training projects are listed separately.

Names and addresses of the principal investigators are provided.

Mid-American Conference on Migratory Labor. *Council of State Governments and President's Committee on Migratory Labor; 1959; 50 pages.*

This presentation of the conference proceedings includes recommendations, papers by the principal speakers, and general discussion summaries on children and youth, housing and sanitation, public health and public assistance, and employment.

Copies may be obtained from the President's Committee on Migratory Labor, U.S. Department of Labor, Washington 25, D.C.

Directory of State and Territorial Health Authorities, 1959. *PHS Publication No. 75; 1959 revision; 102 pages; 35 cents.*

Revised as of May 1959, this directory lists personnel of each State and Territorial health department. Included also are officials of other State agencies directing grant-in-aid programs of the Public Health Service and of the Children's Bureau grant program for crippled children's services.

Personnel of the Public Health Service in charge of functions closely associated with State health departments are listed in the appendix.

Serologic Tests for Syphilis, 1959 Manual. *PHS Publication No. 411; revised 1959; 142 pages; \$2.50.*

This water- and grease-proof plastic covered manual provides a ready reference to the latest technical procedures for performing each of the serologic tests for syphilis

commonly employed in the United States.

New tests include fluorescent treponemal antibody, rapid plasma reagin, *Treponema pallidum* complement fixation using small volumes, *T. pallidum* immobilization, one-fifth Kolmer with Reiter protein antigen, and the Kahn test with cardiolipin antigen.

General information and general equipment are included as well as an appendix which describes methods of collecting and preserving sheep blood, preparation of hemolysin, preparation and preservation of complement, and use of merthiolate as a bacteriostat.

Proceedings, 1959 Biennial Conference of the State and Territorial Dental Directors. *PHS Publication No. 698; 1959; 62 pages.*

Principles of human behavior derived from behavioral research and their implications for dental public health practice are the subjects of seven papers. Also included are the address by the president of the Association of State and Territorial Dental Directors, recommendations of the conference, and recommendations of the association.

Sinus Infection (Sinusitis). *PHS Publication No. 172 (Health Information Series No. 34); revised 1959; leaflet; 5 cents, \$2 per 100.* Presents latest information on sinusitis, outlining causes, signs, prevention, and treatment.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D.C.

The Public Health Service does not supply publications other than its own.

APPORTIONMENT OF FINANCIAL AID FOR COUNTY HEALTH WORK

By ELBRIDGE SIBLEY, Statistician, Tennessee State Department of Health, and
JOSEPH W. MOUNTIN, Surgeon, United States Public Health Service

INTRODUCTION

There is rapidly developing in the United States a plan of local health organization commonly known as the county health department. Under this plan the rural portions of the county, as well as the contained cities and towns, are served by a single health department. These departments have developed, in most instances, under the leadership and guidance of the State health department.

Financial aid from the State and other sources outside the county has played an important part in the development and stabilization of this movement; yet there does not seem to have been developed an equitable plan of apportionment which could be applied successfully under varying conditions.

PURPOSE OF STATE AID¹

In general, there are three major ends to be served by any system of subsidies from central to local governments for health work: First, a subsidy may be used to encourage the initiation of new projects; second, a system of aid provides a desirable channel through which the central health agency may discharge its responsibility to the local unit of government; third, the subsidy can ease the burden of relatively poor counties and thus make possible a more uniform grade of continuing service.

JANUARY 3, 1930, pp. 1-10

Elbridge Sibley and Dr. Joseph W. Mountin outline plans of apportioning subsidies to local health departments appropriate to the purpose of the aid as well as to local circumstances and resources.

Characteristics of patients and services received in mental health clinics in the United States are summarized for 1955-56 from data supplied by a continuing reporting system.

First National Report on Patients of Mental Health Clinics

ANITA K. BAHN, B.A., and VIVIAN B. NORMAN, B.S.

A NATIONWIDE program of statistical reporting for outpatient psychiatric clinics was established in July 1954 by the National Institute of Mental Health in cooperation with the State mental health authorities. The purpose of this reporting is to provide a nucleus of uniform data on outpatient psychiatric services to aid in planning programs and facilities on a national, State, and community basis. These data also aid clinics in reviewing their own operations. As a practical first step, reporting is limited to the mental health clinics with outpatient services and a psychiatrist in attendance at regularly scheduled hours who takes the medical responsibility for all clinic patients.

The first publications derived from the reporting program were a national directory of clinics (1) and a monograph describing the characteristics and staff of outpatient psychiatric clinics (2) based on data submitted for 1954-55 by more than 95 percent of the clinics in the United States. In this article we are summarizing for the first time national data reported on the characteristics of clinic patients and the services they receive based on infor-

mation for 1955-56. Several State mental health authorities have issued reports on the data submitted by clinics operating in their jurisdictions (3-7). A national report on the community service activities of outpatient psychiatric clinics will be published later.

Although the national statistical program limits requested data on patients to a minimum of basic items of information, collection is difficult. The complex and varied pattern of outpatient psychiatric service causes many problems of definition. To yield uniform data, the definition of a patient, type of service, and diagnostic classifications in particular continue to require review and modification. In many instances it was necessary to install new clinic recordkeeping systems and mechanical tabulating procedures at the State level (8). As a result, by 1956 only 499, or 39 percent, of the 1,294 outpatient psychiatric clinics in the United States were reporting information about their patients.

The number of clinics reporting, by type of clinic and by State, is shown in table 1. Data on patients were reported for some but not all clinics in most of the States. Reporting procedures have since been established for the clinics of the Veterans Administration, the clinics in New York State, and additional clinics in other States.

Since the clinics that reported in 1956 are not

Mrs. Bahn is chief and Miss Norman is a staff analytical statistician, Outpatient Studies Section, Biometrics Branch, National Institute of Mental Health, Public Health Service.

a probability sample of all clinics in the United States and difficulties of definition still exist, the findings in this summary are provisional and no comparisons are made between States, communities, and types of clinic. These data on nearly 500 outpatient psychiatric clinics, however, provide some insight into the characteristics of patients and the services provided by these facilities. The data also provide a basis for estimating total clinic patients in the United States.

Although outpatient psychiatric clinics perform professional training, research, educational, and other important community serv-

ices, the largest proportion of total effort is spent in direct services to patients with mental disorders or emotional problems who come to the clinic for diagnosis and treatment.

The following definition of a patient was established for statistical reporting: An adult is classified as a patient upon his first face-to-face interview about his own situation with a professional staff member; a child becomes a patient at the time of the first professional interview with the parent or parent substitute about the child's difficulty. If a parent, spouse, or other related person is diagnosed and accepts a separate treatment plan, he is transferred

from collateral to patient status. Services to a patient are considered terminated upon completion of treatment or other appropriate action, or when the patient fails to return to the clinic within 90 days.

Patient Caseload

An estimate has been made of the total patient caseload, by age and sex, for all clinics in the United States for 1955, based on reports submitted by approximately two-fifths of these clinics. The estimate was based on two assumptions. First, it was assumed that for each type of clinic, those serving children only, children and adults, and adults only, the ratio of child and adult patients to professional man-hours was the same in clinics not reporting number of patients as in those reporting. Second, it was assumed that the child and adult patients enrolled during the year had the same relative age-sex distribution as those for whom services were terminated (only sex and minor age groupings are reported at this time). Data on patients of Veterans Administration clinics were estimated separately and based on reports on a sample of patients.

The estimates provide a description of the outpatient psychiatric clinic population in the United States during 1955, but these data do not indicate the total number of mentally ill

since the clinic population is the result of many selective factors. The relationship of the total number of clinic patients to the total mentally ill is unknown.

An estimated 379,000 individuals were clinic patients during the year. This total is composed of 197,000, or 52 percent, children under 18 years of age and 182,000, or 48 percent, adults. Based on these estimates, therefore, 355 children and 171 adults among each 100,000 persons in the total population of the United States were clinic patients during 1955 (table 2).

An earlier survey (9) reported that there were 150,000 child patients, or 330 per 100,000 population, in the United States in 1950. The apparent increase in child clinic patients from 1950 to 1955 may reflect, in whole or in part, differences in definitions and methods of estimation.

The 1955 estimates indicate that among each 100,000 children in school age groups from 5 to 17 years, probably between 400 and 500 were clinic patients sometime during the year. The estimates also show that there would be about 130 preschool children, 250 adults aged between 18 and 44 years, less than 100 adults 45 to 64 years of age, and only 35 aged 65 years and over. The decrease with age in the number of persons under care in clinics during a year per 100,000 population contrasts

a probability sample of all clinics in the United States and difficulties of definition still exist, the findings in this summary are provisional and no comparisons are made between States, communities, and types of clinic. These data on nearly 500 outpatient psychiatric clinics, however, provide some insight into the characteristics of patients and the services provided by these facilities. The data also provide a basis for estimating total clinic patients in the United States.

Although outpatient psychiatric clinics perform professional training, research, educational, and other important community serv-

ices, the largest proportion of total effort is spent in direct services to patients with mental disorders or emotional problems who come to the clinic for diagnosis and treatment.

The following definition of a patient was established for statistical reporting: An adult is classified as a patient upon his first face-to-face interview about his own situation with a professional staff member; a child becomes a patient at the time of the first professional interview with the parent or parent substitute about the child's difficulty. If a parent, spouse, or other related person is diagnosed and accepts a separate treatment plan, he is transferred

¹ Of 499 reporting clinics, 11 did not provide information on diagnosis.

laterals (parents, spouses, or others) in the interest of a number of patients. In group sessions, one interview is counted for each patient or collateral present. An average of five persons were present at each group session.

About one-third of the reporting clinics held group sessions. Clinics serving only alcoholics reported the highest proportion (16 percent) of interviews in groups.

Diagnoses of Patients

At the time a case is closed, the psychiatric disorder of a clinic patient is reported according to classifications given in the Diagnostic and Statistical Manual of Mental Disorders of the American Psychiatric Association (10).

Prior to the initiation of nationwide reporting, a descriptive sentence or paragraph frequently was used in place of standard terms in recording a diagnosis, particularly of a child patient. A number of general and technical problems resulted from this transition. That is, differing opinion as to the usefulness of recording a single diagnostic term, difficulties in classifying some patients, particularly children, according to the diagnostic definitions, and a lack of uniform interpretation of definitions have been encountered (11).

Of the 135,000 patients on the rolls of reporting clinics during 1956, services were terminated for about 87,000. A psychiatric disorder was reported for 74 percent of these patients; the others either were found to be without psychiatric disorder (4 percent) or were not diagnosed (22 percent). Among children under 5 years of age, 15 percent were without psychiatric disorder and 41 percent were undiagnosed (table 3).

The undiagnosed include (a) patients who were ineligible for service and were referred elsewhere, (b) patients who withdrew before complete evaluation, (c) child patients who were not seen by the clinic staff but whose problems the parent discussed with the clinic staff, (d) patients who received psychological testing only, and (e) other patients who for one reason or another received counseling services without a psychiatric evaluation.

Among the 64,000 patients reported with a diagnosed psychiatric disorder, the diagnostic pattern varied markedly by age (table 4 and fig. 2). Data on diagnoses of clinic patients on termination of service do not reflect the extent or distribution of these illnesses in the community. Also information collected on patients at time of termination of service may not be representative of the characteristics of admitted patients or patients on the rolls at any one time.

The most frequent psychiatric disorder reported for children was "transient situational personality disorder" (see definitions on page 954). The relative frequency of this category decreased sharply by early adulthood.

"Mental deficiency," classified as familial or idiopathic, was also a frequent diagnosis (18 percent) for child patients, particularly for the very young. It accounted for one-third of the diagnoses reported for patients under 5 years of age. The proportion declined to 19 percent for patients of early school age and to less than 3 percent among adult patients. This pattern seems to agree with other findings suggesting that by the time a mental defective passes the age of scholastic demands, he tends to disappear from the problem noninstitutionalized population, possibly because he has been placed in institutional care or has made vocational or other adjustment (12).

markedly with similar age data for patients under care in mental institutions (fig. 1). For example, there were approximately three outpatients to each inpatient under 18 years of age and 1 outpatient to 50 inpatients 65 years of age and over.

Almost 300 males but only 176 females per 100,000 in the population were estimated as being clinic patients during 1955. The highest estimated number per 100,000 for boys, nearly 700, was in the age group 10 to 13 years; for girls, less than 400, among those 14 to 17 years. The higher proportion of boys than girls is typical of outpatient clinic caseloads. For adults, the estimated number of patients per 100,000 population was about 200 males and 140 females. About a third of the estimated number of adult male patients were those reported by the Veterans Administration clinics. Some child guidance clinics count parents as collaterals even when they receive clinic treatment on their own behalf. This practice results in some underestimate of the total num-

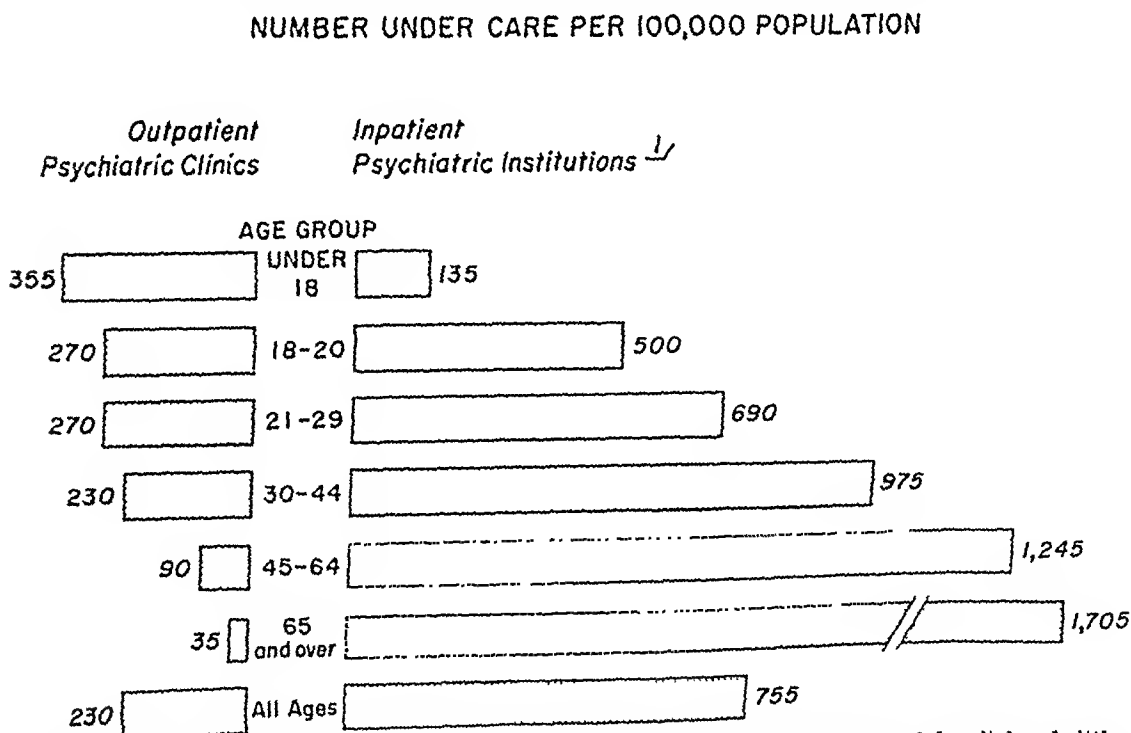

ber of emotionally disturbed adults, particularly for women since mothers are most frequently the collaterals treated by clinics.

Data for the 499 clinics reporting for the year 1956 indicate a rapid turnover of patients in these facilities. A total of 135,000 patients were served during the year. Of this total, 60 percent were newly admitted and 10 percent were readmitted after a previous experience in the same clinic. The remaining 30 percent had continued as patients from the preceding year.

Approximately 990,000 interviews were reported on behalf of the 135,000 clinic patients, an average (mean) of about 7 interviews per patient. Based on detailed information available for patients for whom services were terminated, the median number of interviews is estimated to be about three.

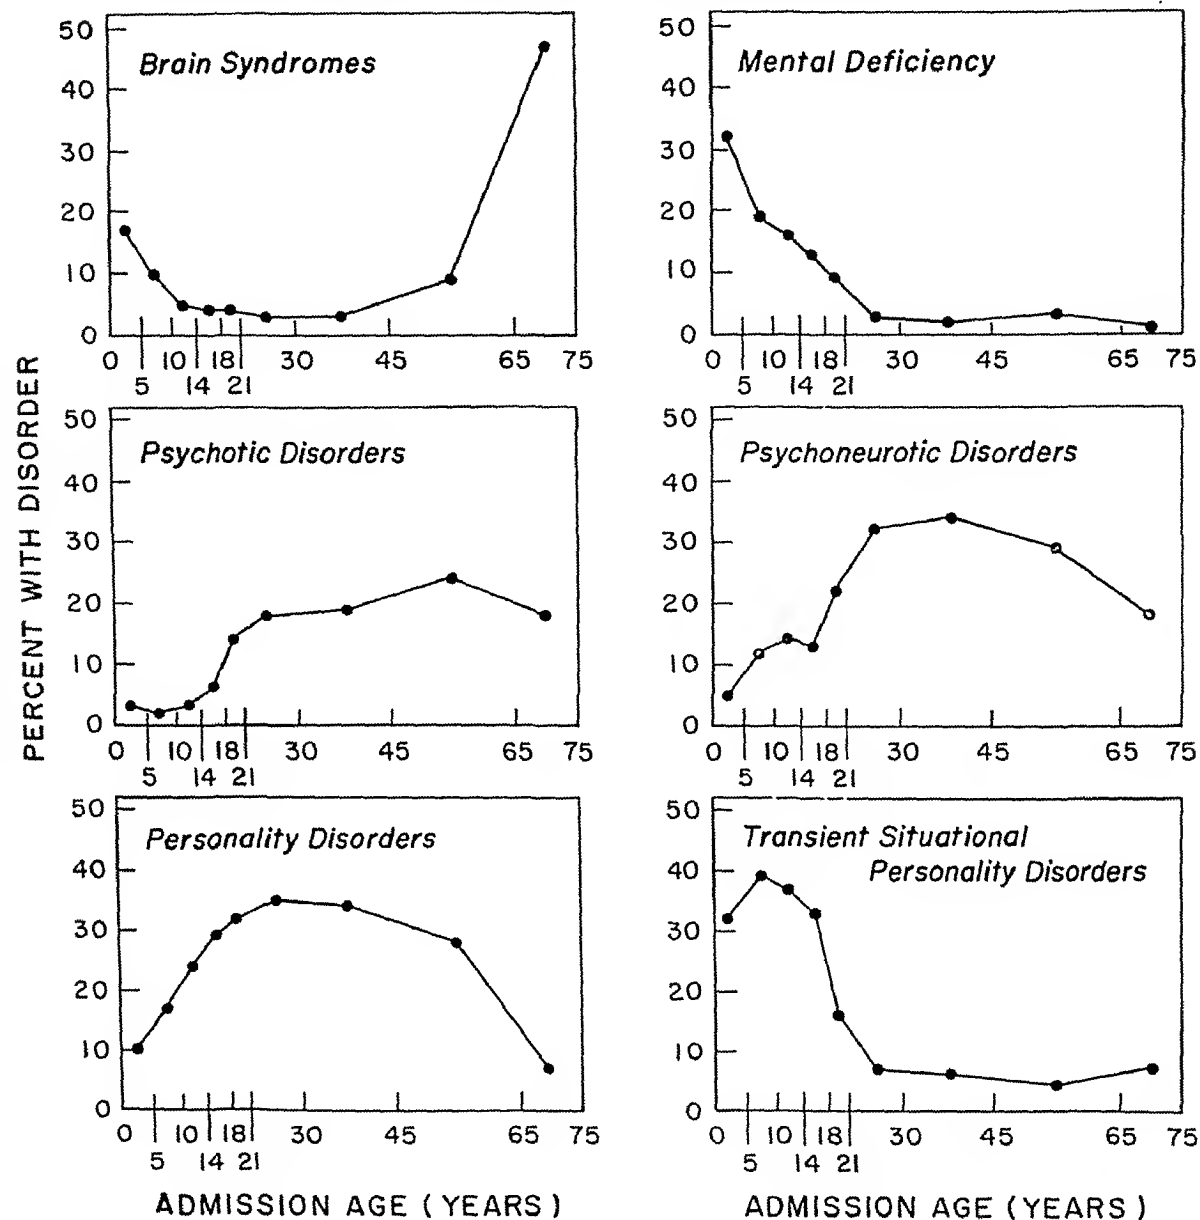

Nearly all of the interviews were individual meetings with the patients, their collaterals, or both. Only 5 percent (47,000 interviews) were held either in group psychotherapy sessions with the patient or in group work with col-

Figure 1. Estimated number of patients under care during the year in outpatient psychiatric clinics and inpatient psychiatric institutions per 100,000 population, continental United States, 1955

^{1/} Includes patients in public and private hospitals for the mentally ill, in general hospitals admitting psychiatric patients, and mental defectives in public and private institutions for mental defectives and epileptics.

Figure 2. Percentage distribution of mentally ill patients for whom services were terminated, by psychiatric disorder and by age group, 488 outpatient psychiatric clinics, 1956

from early childhood through the early adult years. They were only one-tenth of the diagnoses for preschool children, yet as many as one-third of the adults up to 45 years of age were so diagnosed. Among older adult patients these disorders were relatively less frequent. Addiction to alcohol (without recognizable underlying psychiatric disorder) represented about one-tenth of the reported diagnoses in ages 30-64 years. Patients with this

diagnosis were reported by 13 clinics serving alcoholics exclusively and by 161 other clinics. Drug addiction was much less frequently a primary diagnosis of clinic patients. Less than 1 percent of all adults reported were classified with this personality disorder. And drug addicts were identified by only 68 clinics.

"Psychoneurotic disorders" were reported for 13 percent of the child patients; the percentage was more than twice as high among all adults.

"Brain disorders (acute and chronic)" also represented relatively frequent diagnoses for the very young patients (17 percent of those under 5 years of age). At these ages, such disorders are usually associated with prenatal etiology or birth trauma. These disorders were less frequently a diagnosis for child patients of school age. Only 10 percent of those in the early school years (5 to 9 years of age) and no more than 5 percent of the child patients 10 years of age and older were reported with a diagnosis of brain syndrome. Brain syn-

dromes were relatively infrequent as a diagnosis among adult patients except for the aged where, due primarily to cerebral arteriosclerosis and other degenerative changes, brain syndromes represented almost half of all disorders. Brain syndromes associated with convulsive disorders (idiopathic epilepsy) accounted for less than 3 percent of the diagnoses in all age groups.

In contrast with brain syndromes, "personality disorders" increased in relative frequency as a diagnosis with each successive age group

Figure 3. Percent of patients for whom services were terminated receiving treatment for psychiatric disorder, by diagnosis and age group, 468 outpatient psychiatric clinics, 1956

Less than one-fifth of the patients with mental deficiency or brain syndrome, excluding those associated with convulsive disorder, were treated in the clinic. One-third of the children and two-fifths of the adults with psychotic disorders were treated. Generally, one-half of the patients with other disorders were treated.

The amount of service a patient receives is indicated by the number of face-to-face interviews with the patient or with his family or with others, such as an agency worker on behalf of the patient. Length and quality of interviews are not measured. Interviews over the

telephone, case conferences, and a variety of other clinic activities in the interest of the patient are not counted.

For most patients, services were terminated after only a few interviews. More than one-fifth had only one interview and three-fifths had less than five; the median number of interviews was three (table 5). It is estimated that approximately one-half of all reported interviews on behalf of patients for whom services were terminated were interviews with the 8 percent who had 25 or more interviews.

Eighteen percent of the child cases and 28

One-third of the reported diagnoses for adult patients 21 to 44 years of age were in this category. The sharp increase in the relative frequency of this disorder reported for patients in early adulthood, interestingly, is approximately of the same magnitude as the decrease reported for transient situational personality disorders.

"Psychotic disorders" were relatively rare (4 percent) among children but accounted for one in five diagnoses for adult clinic patients. The greatest increase in relative frequency occurred in early adulthood. Schizophrenic reactions strongly predominated among psychotic patients less than 45 years of age. After this age, involutional psychotic reactions and affective (manic-depressive) reactions were increasingly important. Paranoid reactions were of minor numerical importance in all age groups.

Less than 3 percent of the diagnoses for each age group were "psychophysiological autonomic and visceral disorders."

Clinic Service to Patients

The type and amount of service a clinic patient receives is determined by such factors as clinic policies, availability of clinic staff and other community resources, reasons for referral to the clinic, and patient and family cooperation, as well as diagnosis.

The type of service is classified at the time the case is closed into three principal categories: (a) diagnosis and treatment, (b) diagnosis only, and (c) other services only, including psychological testing only. "Other services only" in general include situations previously enumerated for patients reported as undiagnosed. "Diagnosis only" includes instances where diagnostic evaluation and interpretation have been completed but either the patient was sent elsewhere for treatment, he left before treatment was initiated, or treatment was not indicated. "Treatment" is considered to begin only after a diagnostic evaluation or determination of the problem and includes individual or group psychotherapy, counseling of parents, or other types of therapy provided by the psychiatrist, clinic psychologist, psychiatric social worker and other professionals. Patients reported "treated" may not have completed the prescribed treatment.

Of each 10 patients for whom service was terminated in the reporting clinics in 1956, on the average 3 had received both diagnostic and treatment services, 5 had received diagnostic evaluation but no treatment, and 2 had received only a partial psychiatric evaluation, application interview, referral, or other services (table 5). A larger proportion of adult patients than child patients received treatment (two-fifths of the adults and one-fourth of the children). To some extent this difference reflects the relatively high proportion of children undiagnosed. In addition, a larger proportion of child than adult patients were mentally deficient, a disorder often not treated in psychiatric clinics. For nearly every psychiatric disorder, however, the proportion treated is greater for adults than for children (fig. 3).

Table 5. Type and amount of outpatient psychiatric clinic service received by patients for whom service was terminated, by major age group, 1956¹

Objective criteria for classifying and validating change in the degree of impairment are needed to evaluate adequately the outcome of treatment.

Discussion

Data available for 1955 and 1956 on about 500 mental health clinics located in almost every State provide a basis for estimating the total number of clinic patients in the United States by age and sex, and for describing the psychiatric disorders of patients and services performed. Patterns of experience evident from the limited data provide a starting point for assessing outpatient mental health services.

While the data suggest some preliminary answers to questions on the patients served by mental health clinics and the services received, they also raise pertinent questions for research. Some relate to general areas of investigation presently underway and others to possible new areas.

First, more comprehensive clinic reporting is needed for a national analysis of clinic patient characteristics and services. It would also permit comparisons between States and between types of clinics, such as child guidance clinics and clinics serving both children and adults, clinics in rural health departments, and those in university medical centers. Observed differences still may be difficult to interpret, however, because of wide variation in available facilities, purpose, orientation, policies, and practices.

The nationwide clinic reporting program collects only summary data from each clinic and is necessarily limited in scope. Information recorded on mechanical tabulating cards for individual patients has been made available for national use on about 100,000 patients for whom services were terminated in 1957. These cards contain additional information on referral source, reasons for termination, recommended disposition, and fact of previous clinic admis-

percent of the adult cases were closed after one interview. About one-fifth of the patients in both age groups had 10 or more interviews. Only slightly more than one-half of all interviews reported for children were interviews with the patients; 42 percent were with a parent and 6 percent were with another significant person such as a welfare or social agency worker seen on the child's behalf. Ninety percent of the interviews reported for adults were with the patient himself (table 5).

The number of interviews is related to the type of service received. Special tabulations, provided by more than 220 of the 499 reporting clinics, indicate a median of 12 interviews for treated patients, while for those receiving diagnostic evaluation, usually with interpretation and referral service, the median was 3 interviews. The median number of interviews for both diagnostic and treatment services was about twice as high for child as for adult patients (table 6).

Child and adult patients with brain syndromes or mental deficiency had a pattern of receiving fewer interviews than those with a nonorganic disorder. The largest number of interviews per patient was reported on behalf of children with a psychoneurotic disorder (table 7). A large proportion of child patients, as many as 20 percent of those under 5 years of age, received psychological testing only, primarily for adoption, home, or school placement. More than 70 percent of these pa-

tients had only one or two interviews. Relatively few patients 65 years of age and over were treated and most received only a few interviews.

Data are collected routinely as to whether the patient is improved or unimproved or worse after treatment, based simply upon the best judgment of the therapist or clinic staff. Any gain in the patient's condition at termination as compared with admission is considered improvement; the improvement may be not only in mental state, symptoms, or social adjustment, but also in the environmental or familial situation.

Three-fourths of 11,300 child patients, and two-thirds of 13,600 adults for whom results of treatment were reported upon termination, were classified as improved according to this definition. The proportion improved was highest among patients with those disorders most frequently treated. Between 45 and 55 percent of patients with brain syndromes, mental deficiency, psychotic disorders, alcoholism, and drug addiction were reported as improved. Among patients with other disorders, all of psychogenic origin, between 70 and 80 percent improved. In most diagnostic groups, more favorable results from treatment were reported for children than for adults, but the differences were not marked and may reflect in part differences in the types and severity of illness for the two age groups and possibly also differences in the criteria used by the staff.

Table 6. Number of interviews with or about patients for whom service was terminated since latest admission, by type of service and major age group, 227 outpatient psychiatric clinics, 1956

Type of service	Total number of patients	Percentage distribution by number of interviews with or about patient						Median number of interviews
		1	2	3-4	5-9	10-24	25 or more

Diagnosis only	7,488	26.6	29.9	21.8	9.1	2.3	.2	2
Other services only	2,704	57.7	22.9	11.5	5.6	2.0	.3	1

patients reported as undiagnosed at the time service was terminated also poses a number of questions in methodology and analysis.

Clinic admission rates, services received, and results after treatment are probably related to such demographic and familial characteristics as marital status, education, occupation, and type and size of family—all items of information not collected annually in the nationwide reporting program. A special study of such possible correlates is being considered in limited geographic areas for 1960.

Followup of patients after clinic discharge is needed to answer such questions as: What is the subsequent history of the individual discharged after treatment? How many patients seen for only a few interviews are adequately helped? What proportion of these patients follow clinic recommendations?

Lastly, though representing one of the foremost problems, epidemiological information for clinics alone may be misleading. The patient population is the result of many selective factors and its relation to the total mentally ill population is unknown. The collation of data from the various psychiatric facilities in a community or State, however, can provide important baseline information on the total number of medically recognized mentally ill.

Summary

Based on reports about patients submitted by approximately two-fifths of the outpatient psychiatric clinics, it was estimated that 379,000 individuals in the United States, about 197,000 children and 182,000 adults, were clinic patients during 1955.

The estimated number of patients per 100,000 population was higher for children than adults, and higher for males than females at all ages.

Of the child patients with a diagnosed disorder for whom services were terminated by reporting clinics in 1956, one-third were reported with transient situational personality disorder. Personality disorders and mental deficiency also were frequently diagnosed. Adult clinic patients usually were reported with a personality or psychoneurotic disorder although psychotic disorders were not infrequent.

Of each 10 patients for whom services were

terminated, on the average 3 had received treatment after diagnosis, 5 had received diagnostic evaluation but were not treated, and 2 had received only an application interview, partial evaluation, referral, or other similar service.

Relatively short-term service was reported for many clinic patients. More than one-fifth of the patients whose clinic service was terminated in 1956 had received only one interview and three-fifths, less than five.

At termination of clinic services, a median of 12 interviews was reported for patients who had been treated, and a median of 3 for those who had received a psychiatric evaluation only. Patients with brain syndromes and mental deficiency received fewer interviews than those with nonorganic disorders.

The median number of interviews for children was four; for adults, three. More than one-half the interviews reported for child patients were with the child, 42 percent were with the child's parent, and 6 percent were with another significant person such as a social welfare agency worker seen on the child's behalf. Ninety percent of the interviews reported for the adult patient were with the patient himself.

DEFINITIONS OF MENTAL DISORDERS

DISORDERS CAUSED BY OR ASSOCIATED WITH IMPAIRMENT OF BRAIN TISSUE FUNCTION

Brain Disorders (acute and chronic). Organic brain syndromes characterized by diffuse impairment of brain tissue function (orientation, memory, intellectual functions, judgment, affect). Psychotic or neurotic manifestations or behavioral disturbances may be superimposed. Significantly disturbed intellectual development may also be superimposed if brain disorders are present during infancy and childhood.

MENTAL DEFICIENCY

Mental Deficiency. Defect of intelligence existing since birth without demonstrated organic brain disease or known prenatal cause (formerly familial or "idiopathic" mental deficiency).

DISORDERS OF PSYCHOCENIC ORIGIN OR WITHOUT CLEARLY DEFINED PHYSICAL CAUSE OR STRUCTURAL CHANGE IN THE BRAIN

Psychotic Disorders. Disorders characterized by a varying degree of personality disintegration and failure to test and evaluate correctly external reality.

Psychophysiologic Autonomic and Visceral Dis-

orders. Reactions representing the visceral expression of affect. Such exaggerated long-continued visceral states may eventually lead to structural changes. (Includes diagnoses formerly called "psychosomatic disorders" or "organ neuroses.")

Psychoneurotic Disorders. Disorders characterized chiefly by "anxiety" which may be directly felt and expressed or which may be unconsciously and automatically controlled by the utilization of various psychological defense mechanisms.

Personality Disorders. Disorders characterized by developmental defects or pathological trends in the personality structure, with minimal subjective anxiety and little or no sense of distress. In most instances, the disorder is manifested by a lifelong pattern of action or behavior, rather than by mental or emotional symptoms.

Transient Situational Personality Disorders. Reactions which are more or less transient in character and which appear to be an acute symptom response to a situation without apparent underlying personality disturbance. Includes transient symptomatic reactions of children to some immediate situation or internal emotional conflict.

sions. Thus they should provide answers to many questions on characteristics of patients and services received.

For appropriate interpretation of data on clinic patients, admission rates by age, sex, and psychiatric disorder are needed. The need to relate clinic caseloads to population is illustrated in table 2. For example, because of the estimated relatively large number of patients in each year of age in the 5 to 9 group, it would appear that children of early school age have a somewhat greater risk of referral to clinics than other children. However, because of the relatively large number of children 5 to 9 years old in the general population, the clinic caseload per 100,000 population is actually lower for this age group than for the older children. Reporting by all clinics serving a geographic area is a prerequisite for such studies.

As an aid in interpretation of the data, fur-

ther information should be collected on the admission and service policies of each clinic. Services to patients in clinics organized solely for diagnosis of court cases, for example, will differ from clinics where therapy is a planned objective.

Field studies, professional workshops, and other efforts are needed to improve uniformity of definitions and their interpretation and to insure the quality and reliability of the data. In particular, considerably more work is required at all levels on the diagnostic classifications of child patients.

Further work is also necessary on methodology of reporting. For example, as a first step in this new reporting program, detailed information on patients is collected at the time of termination of services and little information is reported at admission. The bias resulting from this method requires study. The lack of a psychiatric description for 22 percent of the

The opportunity to observe every environmental aspect of a patient's life is afforded the staff of a mental health clinic located within a settlement house serving a large community in New York City.

A Settlement House Approach to Community Mental Health

ANNE LAMBERT, M.S., MARGARET S. MAHLER, M.D.,
and VIRGINIA M. MOORE, M.D.

A PSYCHIATRIC clinic, known as the Hudson Guild Counseling Service, offering diagnostic and treatment service to children, adolescents, and their parents, individually and in groups, is operated by the Hudson Guild, a settlement house in New York City. This psychiatric clinic is not part of a hospital. It is a special division of the Hudson Guild's community service, which carries also a day-care and nursery program (ages 3 to 6), and a group work program for school-age children (both preteens and teenagers) and adults. It is a community service established with the objective of meeting the mental health needs of a neighborhood composed primarily of residents of a low-income housing project. Sixty-six percent of the tenants are Negroes or Puerto Ricans.

The following factors led to the establishment of the Hudson Guild Counseling Service:

1. The growing complexity of mental health needs in a rapidly changing, multiracial neighborhood and the resulting increases in demands on the settlement house staff.

2. The special demands for help with mental

health problems of children, stressed by the 608 families of young veterans who moved into the newly opened John Elliott Housing Project in 1947.

3. The strategic position of the settlement house, making the service readily accessible and usable by the community.

Ordinarily psychoanalysis and psychotherapy are accessible mainly to middle-class or high-income families. In facing the need of members of our families for psychotherapy, we were also faced with the need for seeking new ways and means of providing it. A concerted effort of various agencies in and around the settlement under the guidance of the counseling service seemed to be the logical approach.

Sponsorship and Staffing

The initial project, licensed by the State as a psychiatric clinic in 1951, was sponsored in its beginning year by the Hudson Guild alone. In the following years until 1955, the counseling service was sponsored jointly by the settlement house and the New York State Committee for Mental Health. Since 1955, the New York City Mental Health Board has become the secondary sponsor.

When the counseling service opened in October 1948, funds available were sufficient to

Miss Lambert, before her death in August 1958, was a psychiatric caseworker and director of the Hudson Guild mental health clinic. Dr. Mahler and Dr. Moore are psychiatrists on the clinic staff.

National Science Foundation Fellowships

The National Science Foundation is accepting applications for fellowships for advanced study in the physical and social sciences. The deadline for applications is January 1, 1960, and the final selection of fellows will be announced March 15, 1960.

Fellowships will be awarded in the following fields: the mathematical, physical, medical, biological, and engineering sciences, anthropology, psychology (excluding clinical psychology), geography, mathematical economics, econometrics, demography, information and communication theory, experimental and quantitative sociology, history and philosophy of science, and interdisciplinary fields.

Fellows will be selected on the basis of ability, and applicants are required to take the graduate record examination.

Annual stipends vary from \$1,800 for those entering or with less than 1 year of graduate study to \$2,200 for those beginning the final year of training for the doctoral degree. Dependency allowances of \$500 per year for a spouse and for each dependent child are normally available. Tuition, laboratory fees, and limited travel allowances are also provided.

Applications and further information may be obtained from the Fellowship Office, National Academy of Sciences-National Research Council, 2101 Constitution Avenue, Washington 25, D.C.

The teaching is also aimed at developing more understanding of deviational behavior and its causes.

These seminars are conducted with the active participation of all members. Reports are given on individual cases or group activities, assignments of appropriate reading material are discussed, and the like, but the seminars are aimed at synthesization of general knowledge with the facts given on individuals and groups.

We believe that the following professional groups could benefit from training placement in such a service: psychiatric caseworkers interested in work with children and parent-child relationships; students of social organization seeking to obtain an understanding of interaction between personality factors and social conditions; group work students, who may become sensitized to the personality structure of the individual and so acquire a special skill in doing group work in a psychiatric setting; and psychiatrists who seek training in the community aspects of mental health.

The Caseload

The primary objective of the counseling service has been to meet the mental health needs of children and adolescents. This objective was the determining factor in evaluating the caseload of the clinic. We established the following policy.

All requests or self-referrals for mental health services are given attention to the extent that the problem at referral is diagnostically understood. If the problem falls beyond the scope of the clinic, a referral to an appropriate resource in the community is made. In making such a referral, care is taken to prepare the person and the agency for the contact.

Collaboration between the counseling service and agencies referring cases, especially the children's center and the group work department of the Hudson Guild, starts at the point of referral and continues through diagnostic study and treatment. The collaboration takes the form of interdepartmental conferences. At the initial conference, the basis for the referral is discussed; reports are obtained from the nursery and public school teachers, and from group workers; observational and informa-

tional material on the family acquired from participation in the settlement house program is developed and is extremely valuable in reaching a decision on acceptance and further disposition of the case.

Several questions arise. How much can really be done in cases of severe disturbances? Is the effort to help commensurate with the results? Is a mental health service needed for lesser problems? Our experience has shown that no matter how much or how little is done, it should be done with awareness of what is being done and what is left undone. To get this clear awareness, a solid diagnostic study is very much indicated—not for the purpose of labeling but for the purpose of understanding the degree of pathology, the presence of positive strengths, and the interrelation of those strengths within the individual and the family. It is for this reason that we consider one of the functions of a community mental health service in a setting such as ours is to arrive at a diagnostic understanding of the problem referred in the intake study, even in cases which are then referred to other resources, possibly in another community.

Our intake policy has been to carry out the diagnostic study as soon as possible, establishing priority for acceptance on the basis of the results. The wealth of authentic, factual information available to us through the physical location of the clinic within the settlement house, with its close-knit ties to community life, plus the extensive diagnostic study, permits us to differentiate the further disposition of the case as follows:

1. In cases where children can be helped while remaining in their groups, guidance of the nursery teachers or group workers and treatment of the parents is given by the clinic.
2. Adolescents, in need of treatment but not ready for it, are worked with by our group leaders under the guidance of the counseling service, in preparation for a contact with the clinic.
3. Children in need of individual treatment and parents in need of a treatment contact in relation to their children's problems comprise the bulk of the clinic's caseload. It is for these children that frequently a multifaceted treatment is set up.

hire one full-time caseworker, one part-time psychiatrist and one part-time secretary. At present, it has a staff of three part-time psychiatrists, two part-time psychologists, two full-time and four part-time caseworkers, one group therapist, one group therapy consultant, and five psychiatric casework students.

The medical director of the counseling service is one of the psychiatrists. He is also supervising psychiatrist and the diagnostician for adolescents and adults. The second psychiatrist is the clinic's chief consultant for the pre-school child. The third psychiatrist diagnoses school-age children, leads initial team conferences, and treats some children.

The counseling service director and case supervisor is a psychiatric caseworker. She is also in charge of the training program for psychiatric social workers as well as the coordinator of the special projects sponsored by the service.

In developing the staffing pattern, we considered it essential to have psychiatric caseworkers professionally well qualified, capable of using supervision constructively, and interested in working in the community. It was found most economical (and not only in the budgetary sense) to use competent psychiatrists according to their area of specialization. In selecting psychologists, we looked for ability in testing and additional training in therapy. These staff qualifications permit us to use representatives of all three professions in treatment, the psychologists and caseworkers working under a psychiatrist's supervision.

The supervising psychiatrist (medical director) maintains a constant inservice training program for the staff. Actually, the psychiatrist supervises the treatment in individual conference with the caseworker. At intervals, case review conferences are held at which the case supervisor is present as well as all workers active with the family. It is at these conferences that the community aspects as well as the general treatment policies of the clinic are considered.

Difficulties with the untrained workers who comprised the staff of the group work department—the social service area related to group activities of school-age children and adults—arose at the inception of the counseling service.

These difficulties were related to the staff's unwarranted apprehension that the ability of a counseling service worker to help a child who displays behavioral deviations within the group would, by implication, undermine the professional status of the group worker. There were other thoughts and apprehensions as well.

These difficulties resulted in a turnover in this department's staff, replacing untrained workers with trained.

It was a much slower process, however, to develop understanding of the counseling service, even with a trained staff. In view of these complexities, special emphasis was placed on clarification of the role of the counseling service within the setting of the settlement house.

Stimulation of understanding within the group work department was aided through placement of students from the New York School of Social Work, bearers of the professional approach, within the framework of the department as professional working observers. The trained workers on the staff of the group work department are fully occupied with their administrative functions. The actual work with the groups is carried on by volunteers and part-time workers giving limited time. Thus the students are the only workers with the time and interest to concentrate on their groups, eager as they are to intensify their training through a liaison contact with the counseling service.

In the last 2 years, the counseling service has supervised group work students on special assignment, with emphasis on psychiatric orientation.

Since 1955, the State Committee for Mental Health has been sponsoring an enlarged training program for psychiatric social workers. A small number of these in-training workers have been placed with the counseling service since January 1949.

In addition to training programs for the counseling service staff itself, seminars with staff workers from the other departments of the Hudson Guild are held frequently. At these seminars, the work of the counseling service is explained and factual knowledge conveyed about children in different ages and stages of development (biological, social, emotional, structural, and behavioral differences).

2. The evaluation of the child's problem in the intrafamilial psychopathology, and of the role of the deviant child in cementing the intrafamilial pathological emotional balance.

3. The combining of a nursery of good educational standing with a good clinic staff.

At the opening of the counseling service in 1948, there had been a teaching and working contact of 3 years' duration between the day nursery, called the children's center, and the psychiatric caseworker who became director of the service. Thus the establishment of the counseling service presented an opportunity to expand and deepen the contact. From the very beginning, the collaboration was focused on improving the diagnostic methods, intensification of efforts to improve timing of referrals, and closer and more intensive work with the children referred.

Other factors contributed toward the productivity of this collaboration. The children's center was adequately staffed quantitatively and qualitatively. The general educational level of the nursery program was high. The nursery teachers and parents of the younger children were willing to work toward better understanding and handling of the children.

In view of these contributing factors, the counseling service has been able to carry the basic program with the children's center and also to launch small study projects. A study of 6-year-olds and a study of early "runners-away" are examples. These projects have culminated in the demonstration project, the therapeutic nursery group for 4- to 5-year-olds.

The idea of the pilot project arose when we realized that the most intensive and extensive outbreak of difficulties occurred in the whole group aged 4 years. The nursery staff at times felt that the whole group should be referred to the counseling service. This particular phenomenon, understandable in the given developmental stage, led to the idea of trying out the medium of group therapy for those children referred to the service. This project is in its second year. A third year will be necessary in order to arrive at more definite conclusions.

So far, the experience of the first year has shown that children of this age do respond to modified activity group therapy. All children in this therapeutic group have shown progress

and improvement in varying degrees, corresponding to the severity of their difficulties. The children whose deviations were reactions to family attitudes and environmental conditions, have "blossomed" in response to their therapist's handling and to a better understanding by their parents. These children also have been able to function differently in the large nursery group from which they were originally taken to the therapy group. Children with more severe disturbances have shown improvement in their adjustment and relationships to age-mates although their basic disturbances remain.

Under the guidance of our psychiatrist for this age group, we have been able to achieve positive results in the majority of cases in correction of deviational behavior and of developmental growth problems and in strengthening emotional stability.

Positive results have been achieved with parents of younger children in the integration of changed attitudes. Individual contact with the parents has been a part of our study and treatment plan for the child. With most of the preschool children, the contact with the parent (usually the mother) developed into a treatment contact aimed at assimilation of new attitudes toward the child, in accordance with the child's needs and with the parent's capacity to meet them.

Frequently the treatment was focused on the parent's own problems which had led to the difficulty between the parent and child. Where the parent showed a certain degree of self-awareness and insight into the child's difficulty, the contact amounted to counseling. In cases of very disturbed parents, a supportive contact with the parent aimed at forestalling further damage was maintained.

Close collaboration between the counseling service and the children's center has proved invaluable in many ways, particularly in early detection of children's difficulties. Where the deviation was not severe but presented rather a developmental difficulty typical for the given age, it could be helped and would result in a developmental "spurt" of the child. When the difficulty was severe, a thorough diagnostic study enabled us to do "right" from the very beginning. This made it possible to lessen the

Our work with parents in groups started almost with the opening of the service. At first, the group work was educational. It gradually changed into "emotional reeducation."

At present the caseload amounts to 125 cases each month. Primarily, children accepted for treatment have behavioral and personality development problems and impulsive and compulsive neurotic character disorders. There are some borderline cases and problems of parent-child relationship. This means intake and diagnostic studies, individual treatment, and group therapy.

A series of "hardcore" families were referred to our service by the housing authority in December 1956. We started our work with these families with a psychiatric evaluation of the pathology and of the healthy potential of the family unit. We believed this would help us avoid hit-or-miss attempts to clarify what could be done and to concentrate our efforts within the realm of possible achievement. Our main goal was to give appropriate support to these deprived, damaged, and disturbed parents to an extent that would permit us to help the children. Although a grant for this project (which we planned to carry out as a research-in-action project) was not available to support our work with these families, there have been some positive results.

In addition, the clinic has a discussion group for mothers of children 3 to 5 and a therapeutic nursery group for children 4 to 5 years of age. The therapeutic nursery group is a pilot demonstration project under the sponsorship of the New York State Commission on Mental Health.

The caseload consists of 70 percent children and adolescents and 30 percent parents in treatment, and counted as separate cases. In a sizable number of families, more than two members are under treatment.

A constant factor is the waiting list and the large number of cases studied, accepted, but not yet assigned.

Group Work

The group work department of the settlement house conducts the social, educational, and recreational group activities for adults and children. There is no mental health emphasis

as such, but the activities are designed to contribute to the community's mental and social health.

The staff is composed of a graduate social worker, who acts as department supervisor, and five full-time associates, some with degrees in the social sciences and others with advanced training. In any one year, approximately 30 other individuals lead group activities for the Hudson Guild as volunteers or part-time paid workers. In addition, from one to five graduate students from schools of social work in New York City are assigned to the staff as field work placements. All volunteers and part-time workers are skilled in an activity such as handicrafts, dramatics, or dancing.

Group workers are encouraged to request consultation with the counseling service staff whenever they feel they need help in understanding the behavior pattern of a member of their group. When such a request is received, the group worker and a counseling service worker discuss the person and decide whether a formal referral to the clinic is indicated. If it is decided that such a referral is required, the group worker prepares a written report describing the person, his problem, family situation, and his potential acceptance of counseling.

The clinic established this procedure to encourage the group workers to "think through" the help the person needs and is ready to accept. An attempt has been made to avoid either impulsive or inordinately delayed referrals or building barriers to referrals.

From the beginning of the counseling service, the children's center has been the main source of referrals. During the past year, however, there were a large number of teenage referrals from the group work department, and the number of referrals from other Hudson Guild departments has steadily increased.

The Preschool Child

We feel that the specific value of our work with the nursery child lies in:

1. The early detection of deviant behavior (gauged, as it were, by comparison with the normal range of behavior of the identical age group in question).

belongs and that it belongs to him. In other words, he feels that he has a real and personal place in this neighborhood social unit with which he soon becomes highly identified. Therefore, whatever the clinic sets up for him in situ psychotherapy, special group experiences, and treatment contacts with his parents become joined for the child as concrete evidence of his personal importance and place in a specific structuralized social unit—the settlement house.

Everyone needs a sense of possessing positive social significance, but no one needs this more than the severely damaged child whose self-identity requires strengthening. The increasing development of positive object relationships, with their concomitant stimulation of ego development, requires satisfying experiences. When the school-age child achieves gratifying relationships with the individual staff members of the counseling service, to whom he is in reality important as a warmly valued human being, he is concomitantly feeling that he has positive meaning in the wider social context of the community center itself. This serves to reinforce the constructive aspects of his total experience in relation to the Hudson Guild.

It is interesting and significant to see the functioning of these severely damaged children change in response to such a multifaceted treatment plan. Typical of such children is Billy.

At the age of 4 years Billy was placed in the nursery by his mother. His nursery teacher described him as follows: "Billy has a downcast, sad expression on his face, but laughs a gurgling, baby laugh when played with individually. His relation to adults is complicated. He is quite dependent and wants a lot of exclusive attention. He accepts affection hungrily but does not ask for it. When picked up, he just seems to melt into one's shoulders. He is responsive to firmness but bewildered by choices. He is not ready for group activities but resents being left out. When the group is together, he throws himself on the floor with his eyes closed." His relation to other children was further described by his teacher as extremely hostile. "He hits, pushes, pounces on children, pulls their hair or pretty nearly chokes them without apparent reason. He often brushes his

hand in front of his face as though to dispel unpleasantness and trouble."

Billy's disturbed behavior at the age of 4 was rooted in developmental traumata which left him with a great deal of anxiety. Billy is now 9. From the age of 4 until the present, the clinic has been in contact with Billy and his mother. Billy has been given the multifaceted treatment plan in situ, which has included psychotherapy and also therapeutic types of group experiences. He is now in the fourth grade of school. He has done good school work since the first grade and was described by his last teacher as concentrating well upon school work and progressing in each subject. He "participates in classroom discussion, does beautiful art and clay work. He continues to make friends and is popular."

In the last 2 years, Billy has, without regression, met the birth of a third sibling and situational stress at home set up by acute marital discord and increase in his father's alcoholism. He has maintained an obsessive-compulsive line of defense against regression. He feels that he has both peer age and adult friends. He can increasingly express his conflicts and feelings in psychotherapy, and he has developed a far more secure relationship to his mother, who has also been in treatment contact with the clinic. He is still a particularly vulnerable child with ego weaknesses disclosed clearly in his Rorschach, but his functioning has improved tremendously. He can now enjoy social contacts, visualizes himself as having a future, and has achieved modes of mastery and sublimation which are social modes.

It is reasonable to assume that without the early establishment of a treatment plan which anticipated continuing, long-term contact, this severely damaged child would not have ceased to be such a behavior problem in groups where he had become a menace to other children. Neither would he have developed as well his capacity for academic achievement and for finding gratifying and socially acceptable outlets for his fantasy life.

Billy is only one of many children who have been highly deprived in this oral period and whose maturation continues to be uneven because of continued traumatic experience before the age of 4. Children of this type need com-

disturbance or arrest it. Such a lessening of the disturbance would improve the adjustment and functioning of the child at a given period, which had a therapeutic value as well. These children frequently still need therapy at a later point, but they enter therapy with a better prognosis. In a few cases our first contact with a severely disturbed child was at nursery age, and such a child, returning to our clinic in the early teens, benefited from the treatment contact.

The School-Age Child

In the school-age group of children referred to the counseling service, not a few have suffered severe traumata in infancy and early childhood, reflected in ego weakness expressed symptomatically in their behavior and functioning. These children will not respond to relatively short-term treatment. Less damaged and less vulnerable children, when assisted in reducing an immediate phasic anxiety, frequently respond with a developmental spurt which consolidates treatment gains sufficiently for them to make satisfactory adjustment without further clinic help. The severely traumatized school-age child does not possess as much basic ego strength to build upon. Therefore, a proper treatment plan for such a child must anticipate long-term contact which will continue to provide constructive, anxiety-diminishing types of help over a period of years.

Psychiatric treatment is of enormous value and definitely indicated. An adequate treatment plan for these particularly vulnerable children must include, however, more than direct psychotherapy, as the therapist possesses no magic which can provide other kinds of therapeutic experience equally important to such children. A severely damaged child may make increasingly secure contact with his therapist, but the gulf between this contact and the therapeutic vacuum to which he returns outside the clinic can be a gulf too wide for psychotherapy alone to bridge. Mobilization of therapeutic potential requires extension of treatment planning to include usual aspects of the severely damaged child's life, not only inside but outside his home.

In this regard, the very position of a psy-

chiatric clinic in a neighborhood settlement house makes a multifaceted treatment plan, extending constructively into various channels of the child's usual life, easier to achieve in a well-integrated, closely knit fashion.

Since the number of such children is large and the need great, it is highly pertinent to consider what community treatment resources can be developed for them. In this regard, a clinic in a neighborhood settlement house lends itself to becoming such a community treatment resource.

The clinic, through its position, is readily entwined with other strands of the school-age child's specific neighborhood life. Obviously, the more such entwining occurs, the stronger the clinic can make its net of supportive therapeutic assistance. In this respect, it is a very real asset to have the clinic sharing the same neighborhood with the child's home and the school he attends.

As a result, the clinic's clear understanding of the child's personality organization and special needs can be shared with the school, sometimes at the point the child enters the elementary grades. The clinic can continue contact as these nursery children enter the pre-adolescent period between 6 and 12.

The severely damaged child, with low self-regard and insufficient sense of being able to hold his own adequately with peers, can profit by a special facility set up purposively to help him find group contact as therapeutic for him as it can become. This need is supplied as part of a total treatment plan when such a child, with weak ego and low self-confidence, is placed by the settlement house clinic in a special small group (therapy or transitional) which has an adult leader from the clinic staff and group members who are familiar neighborhood peers.

It is significant that when a multifaceted treatment plan for the severely damaged school-age child occurs in a settlement house setting, the child's relationship with the clinic assumes a particular social meaning. The settlement house, as a structuralized social unit, becomes increasingly a part of the child's and the family's neighborhood life. The clinic therefore becomes to the child not only specific contacts at regular intervals with a therapist but also "the Hudson Guild" to which he feels that he

A Preliminary Report On RPR Test for Syphilis Using Unheated Serum

JOSEPH PORTNOY, Ph.D.

WARFIELD GARSON, M.D., M.P.H.

THE RAPID plasma reagin (RPR) test was developed chiefly to permit rapid and economical screening of large numbers of persons so that reactors could be given immediate specific and prophylactic treatment (1). As reported recently (2), the objectives of the RPR test were realized when it was used at the reception center in El Centro, Calif., where large numbers of Mexican farm laborers were processed rapidly and economically by a small staff in an improvised laboratory at the site of operations. The success of the El Centro operation led to the establishment of four additional RPR testing stations on the border between Mexico and the United States.

Observations made during the development of the RPR test had suggested that the RPR antigen suspension could be applied to tests with unheated serum. It was found that the RPR antigen gave a satisfactory level of sensitivity and specificity in the SERA study (3) when 0.05 ml. of unheated serum was tested with 1/45 ml. of RPR antigen suspension.

As an extension of these studies, the testing of unheated serum using the RPR antigen and the same technique as for testing unheated plasma was undertaken. The results of testing two groups of specimens are reported here.

Materials and Methods

One group of 149 specimens was obtained during evaluation studies of anticoagulants for the RPR test on unheated plasma. These specimens were duplicate samples drawn to produce the conventional clotted-blood specimen.

Most (1,740) of the specimens studied were collected in North Carolina during a serologic survey conducted by personnel of the venereal

disease control section, North Carolina State Board of Health, under the direction of Dr. B. J. Rosenblum.

The technique used for testing with unheated serum was as follows:

Preparation of antigen suspension. The RPR antigen suspension was prepared by the method originally described for use with the RPR test on unheated plasma (1).

Preparation of specimens. The blood specimens were centrifuged at room temperature at 1,500-2,000 rpm for 4 minutes. The serum was allowed to remain in the original collection tube. Specimens were then tested without heating.

Performance of test. Procedure was the same as originally described for performance of the RPR test (1), except that three drops of serum instead of three drops of plasma were used with one drop of antigen suspension. Both serum and antigen suspension were at room temperature at the time of testing.

In addition to the RPR test on unheated plasma (performed as described (1) on the first group of specimens only), the other serologic tests used were the VDRL slide (4) and the tpcf 50 (5). These two tests were performed on serum separated from the clot after completion of the RPR test with unheated serum. For both tests the serum was heated at 56° C. for 30 minutes.

Results

Samples of all 149 of the first group of specimens were subjected, over a period of several months, to the four serologic tests. Comparative serologic findings for this group are shown in table 1.

The reactivity rates (the sum of reactive plus weakly reactive results expressed as percentages of the total results) of the four tests were quite similar for this group of specimens. The RPR test on unheated serum and the VDRL slide test were 45.0 percent reactive, the tpcf 50 test was 47.0 percent, and the RPR test on unheated plasma was 49.0 percent reactive.

Dr. Portnoy and Dr. Garson are with the Venereal Disease Experimental Laboratory, Communicable Disease Center, Public Health Service, at the University of North Carolina's School of Public Health, Chapel Hill. Dr. Portnoy is an immuno-serologist and Dr. Garson is laboratory director. Technical assistance was provided by Carl Adams.

munity provision of a specific treatment resource which will focus upon their special long-term treatment needs.

The school-age child has been treated individually and in therapeutic groups (adjustment, transitional, and activity). For the severely disturbed children, we have set up the multifaceted treatment plan as described. The

public school plays an important role in the functioning of this multifaceted treatment plan. At present, a number of these severely disturbed children still on our caseload have been suspended from school. They are not delinquent and are of prepuberty age. A special effort is very much needed to provide the necessary help for these children.

exhibit

A Second Look is Worth 1,000 X-rays

Dual reading of chest X-rays taken in tuberculosis caseload programs is generally recognized as being productive but as yet has not been employed extensively in the United States. The Tuberculosis Branch of the Public Health Service is promoting the use of this technique in tuberculosis control by various means, including the exhibit shown here.

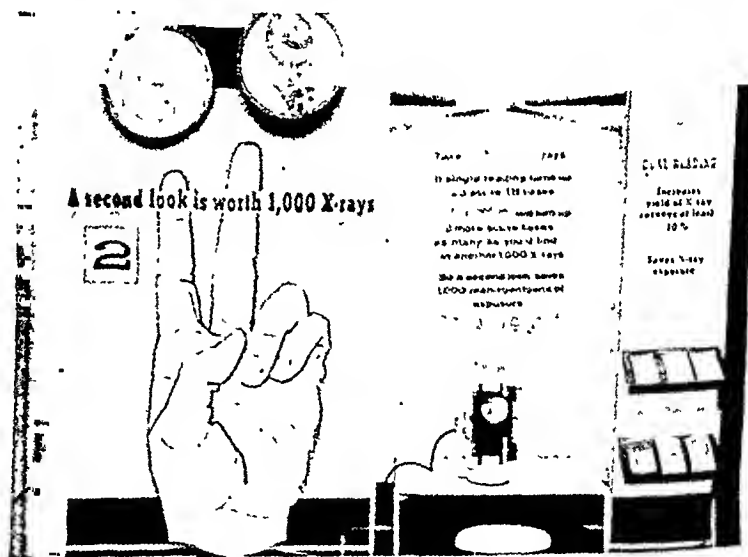

The exhibit points out the two main benefits of dual reading: increased yield of new cases from the same number of films and reduced radiation exposure. A roll of films with examples of suspected abnormalities missed on a single reading is shown in a viewer to allow physicians to check their own interpretations. Reports which indicate that dual reading increases the yield of new cases by at least 10 percent are summarized in an accompanying leaflet, which can be used for future reference.

Designed for use at national, re-

gional, and other meetings and conferences of people concerned with tuberculosis control and exposure to radiation, the exhibit is available free upon request. However, it must be manned by a Tuberculosis Branch staff member, and its availability will depend on whether a member can be assigned. Shipping

costs are paid by the borrower, but leaflets are provided for free distribution.

For further information write the Tuberculosis Branch, Division of Special Health Services, Public Health Service, U.S. Department of Health, Education, and Welfare, Washington 25, D.C.

Specifications: A 3-panel exhibit on legs, fabricated of lacquered plywood and steel framing, 9 feet long, total weight 580 lbs., including 2 packing crates. Only one electrical outlet, 110 a.c., 500 watts, is needed for illumination. The film viewer, containing X-rays, is an integral part of the exhibit.

Table 3. Comparison of results of original RPR test with unheated serum and retest 1 week later of 68 specimens

Type of reaction	Original RPR test with unheated serum	Repeat RPR test with unheated serum stored approximately 1 week		
		Reactive	Weakly reactive	Nonreactive
Reactive.....	16	14	2	0
Weakly reactive.....	2	0	2	0
Nonreactive.....	50	0	1	49
Total.....	68	14	5	49

storage of serum separated from the clot, repeat tests with unheated serum were performed on 68 specimens about 1 week after the first test (table 3). Of 16 originally reactive specimens, 14 were reactive and 2 weakly reactive on the retest. No change occurred for the 2 weakly reactive specimens. Of the 50 originally nonreactive specimens, 1 was weakly reactive on the retest.

Discussion

The results of testing the group of 149 specimens (table 1) indicated a close correlation between the RPR test on unheated serum and the RPR test on unheated plasma, as well as between RPR (unheated serum) and the VDRL slide and tpcf 50 tests. Agreement between test results on the group of 417 specimens (table 2) was somewhat lower.

Most of the disagreement observed for the group of 417 specimens was confined to the 94 specimens which tested either weakly reactive or negative rough on the RPR test with unheated serum (table 2). Since these 94 represented almost 25 percent of the total group of 417 specimens, a greater effect on the degree of agreement for that group could be expected than for the group of 149 specimens, where the 11 weakly reactive specimens comprised only 7.3 percent of total specimens. The percentage of agreement would be higher for the RPR test and both the VDRL and tpcf 50 tests if the specimens giving negative rough reac-

tions in the RPR test with unheated serum and a reactive or weakly reactive result in the other serologic tests (table 2) were considered to be in agreement.

The two groups of specimens also may have undergone dissimilar losses of reactivity due to different lengths of time between the taking and testing of the samples. This is another possible explanation of the lesser agreement of the 417 samples (table 2). The 149 specimens were examined within 24 to 48 hours after withdrawal, but a longer period separated the withdrawal and the testing of the 417 specimens. Although there could thus have been a change in reactivity to the RPR test with unheated serum between the time when these 417 samples were drawn and the time they were first tested, no significant changes in reactivity after the first test were observed in the 68 samples retested about 1 week later (table 3).

Although the RPR test with unheated serum appears to be less reactive than the RPR test on unheated plasma, its reactivity compares favorably with that of the VDRL slide test. The demonstration that RPR antigen can be used in tests with unheated serum widens the field and program usefulness of this antigen, since specimens collected in anticoagulants or in tubes without anticoagulant can be examined rapidly and economically with the same equipment, reagents, and personnel. However, if the objective is to obtain the maximum screening efficiency of RPR antigen, the test with plasma should be employed.

Conclusion

RPR antigen suspension may be used to test unheated serum using the same procedure as for unheated plasma. This broadens the usefulness of RPR antigen in syphilis control screening programs, though its maximum screening efficiency is realized in its use with the plasma test.

Table 1. Comparison of results of RPR test (unheated serum) with results of 3 other serologic tests on 149 specimens

Type of reaction	RPR test with unheated serum	RPR test with unheated plasma			VDRL slide test			tpcf 50 test	
		Re-active	Weakly reactive	Non-reactive	Re-active	Weakly reactive	Non-reactive	Re-active	Non-reactive
Reactive.....	56	55	1	0	50	4	2	53	3
Weakly reactive.....	11	9	2	0	6	2	3	11	0
Nonreactive.....	82	3	3	76	3	2	77	7	75
Total.....	149	67	6	76	59	8	82	71	78

Defining agreement as a reactive or weakly reactive result to one test accompanied by a reactive or weakly reactive result to the other test, results to the RPR test on unheated serum and to the RPR test on unheated plasma agreed in 96.0 percent of the cases. Results to RPR on unheated serum and to both VDRL slide and tpcf 50 tests agreed in 93.3 percent of the cases.

The group of 1,740 specimens obtained from the serologic survey were given the RPR test with unheated serum in the Venereal Disease Experimental Laboratory, with the following results:

	Number of specimens	Percent of specimens
Reactive.....	156	9.0
Weakly reactive.....	48	2.8
Nonreactive.....	1,536	88.3
Total.....	1,740	100.1

On the basis of results, 417 specimens were selected for comparative testing with the VDRL

slide and tpcf 50 tests. The specimens, when sufficient serum was available, included all those which had tested reactive, weakly reactive, or "negative rough," as well as an approximate 10 percent sample of the nonreactives (showing no clumping). Specimens in the "negative rough" category showed some clumping, but less than those categorized as weakly reactive and were reported nonreactive.

The VDRL slide and tpcf 50 tests were performed on these 417 specimens 6 to 7 days after the RPR test with unheated serum (table 2). The RPR test on unheated serum showed the lowest reactivity rate—45.6 percent. VDRL slide test results were 49.9 percent reactive, while the tpcf 50 test, with results 54.5 percent reactive, showed the highest reactivity rate. RPR test (unheated serum) results agreed with VDRL slide test results in 86.8 percent of the cases, with tpcf 50 test results in 82.7 percent of the cases.

To determine the effect on the RPR test of

Table 2. Comparison of results of RPR test (unheated serum) with results of 2 other serologic tests on 417 specimens

WORLD HEALTH FOR WORLD PEACE

Many of the Nation's leaders in medicine, public health, education, science, and industry and leaders in Congress and the executive branch of the Federal Government gathered at the Second National Conference on World Health held in Washington, D.C., May 7-9, 1959. The meeting was sponsored by the National Citizens Committee for the World Health Organization with the assistance and participation of more than 200 health, educational, welfare, civic, and business organizations. The committee was organized 6 years ago to inform Americans about international health problems, the work of WHO and other agencies in solving these problems, and why international cooperation is important both for health and for peace.

Dr. Milton S. Eisenhower, president of Johns Hopkins University, served as chairman of the conference, which was held immediately prior to the 12th World Health Assembly in Geneva. Dr. Ernest L. Stebbins, president of the National Citizens Committee for WHO, opened the conference, which was attended by approximately 1,500 persons.

In addition to providing stimulus and direction, the conference was significant in shaping and clarifying U.S. policy on international health matters, according to Dr. Leroy E. Burney, Surgeon General of the Public Health Service.

More than 50 speakers and discussion leaders ranged over subjects related to international health within the general context of the conference theme, "World Health for World Peace." Following this summary of their comments is the full text of the speech given by Dr. Abraham Horwitz, director of the Pan American Sanitary Bureau, the Regional Office for the Americas of the World Health Organization.

There was striking unanimity in support of a bigger, stronger World Health Organization,

an organization more adequately financed to meet the challenge of a world in which two-thirds of the population live in conditions of disease, malnutrition, poverty, and ignorance.

Speaker after speaker stressed the vital part that world health must play in reaching world peace and stability. And pervading the conference was the feeling that the atomic age had placed humanity at a crossroads, the road to annihilation or the road to peace through cooperation. Dr. Andrew W. Cordier, executive assistant to the United Nations Secretary General, expressed this feeling when he said that "the threat of the atom is a threat which is countered in turn with the promise of the atom, and therefore the delicate balance between that which is destructive and that which gives vast promise is a balance fraught with greater consequences than ever before in the history of the world."

International Understanding

An opinion voiced by several speakers was that, of all the fields of international endeavor, world health is best suited to provide experience in working together without competition in a cause in which all believe. In his opening statement Dr. Eisenhower said:

"Peoples of vastly different cultures can work together in harmony in this noncontroversial area. Here an achievement in one country is a benefit to all others. Here multilateral cooperation is not a subtraction in one nation to achieve addition in another. Rather it is a multiplication of benefits to all. Massive success in international health cooperation could well serve as a model for other efforts to build a cooperative world characterized by peace, freedom, and justice."

Reinforcing this view, Arthur S. Flemming, Secretary of Health, Education, and Welfare stated that "an effective health for peace cru-

New Members of the PHR Board of Editors

Three new members have joined the Board of Editors of *Public Health Reports* for a period of 3 years. Outgoing members are Mary Switzer, Dr. Franklin H. Top, Dr. Maudel E. Cohen, and Dr. Carl C. Datter.

Roger W. Howell, M.D., is currently an associate professor of public health practice in the School of Public Health at the University of Michigan. He has held positions on the faculties of the medical schools of the University of Michigan and the University of Minnesota, as well as in the School of Public Health of the University of North Carolina.

Dr. Howell has worked in public health programs since 1951. He has served on several committees in the American Psychiatric Association and is a member of the Committee on Preventive Psychiatry of the Group for Advancement of Psychiatry. He also serves as a consultant for the Public Health Service in the field of mental health.

Most of Dr. Howell's psychiatric training was obtained at the University of Michigan, where he also received his basic medical training.

Albert L. Chapman, M.D., has been Assistant Surgeon General and chief, Division of Special Health Services, Public Health Service, since 1956. He was regional medical director of Region II during 1954-56, and of Region III in the period 1951-54, after serving 2 years as assistant chief of the Chronic Disease Branch.

After he was graduated from the Long Island College of Medicine in 1937, he received the master of public health degree from Johns Hopkins University

in 1941. Dr. Chapman held the post of regional medical director of the New Jersey State Health Department at Trenton for 2 years. During the following 3 years, he held successive posts with public health agencies at town, county, and State levels and with the Public Health Service in Region II.

Dr. Chapman is a fellow of the American Public Health Association and the Royal Sanitary Institute of England. In addition to membership in numerous professional organizations, he is prominent in activities of the National Safety Council and the American Public Health Association.

Helen M. Wallace, M.D., M.P.H., has been professor of maternal and child health at the University of Minnesota School of Public Health since 1956. Previously she was professor and head of the department of preventive medicine and public health in New York Medical College, 1953-56. During the preceding 13 years, she served in the New York City Health Department as chief of the maternity and newborn division and director of the bureau for handicapped children. Dr. Wallace received the degree of master of public health, cum laude, from the Harvard School of Public Health after earning a doctorate in medicine at the Columbia University College of Physicians and Surgeons.

Besides serving as the current national health chairman of the National Congress of Parents and Teachers, Dr. Wallace is secretary of the maternal and child health section and a member of the committee on child health of the American Public Health Association. She is, in addition, assistant editor of the *Journal of the American Women's Medical Association*, as well as a diplomate of both the American Board of Pediatrics and the American Board of Preventive Medicine.

ous areas in the Philippines, areas now freed from that disease. In one small region in Greece, he said, following a malaria eradication program, the rice yield increased four times. In many countries deficient in food production, like India, potentially rich agricultural lands have lain fallow for centuries, depopulated by the ravages of malaria and other preventable diseases. Such lands are now being brought back into cultivation with the restoration of health, Dr. Rusk said.

Another point developed at the conference was that, once people generally recognize their enormous economic stake in the improvement of world health, they will be more generous in their contributions to the funds necessary to get on with the job.

Dr. Flemming urged voluntary organizations to develop and support private programs to provide medical care and teaching in other nations. "I am convinced that these voluntary groups, through their international organization and counterparts in other countries, can bring peoples of other countries to the point where they will have an appreciation of the values that flow from private groups within their communities taking the initiative in dealing with their own health programs," he said.

Congressman Judd also stressed that voluntary organizations and individuals can make important contributions because they are not bound by government protocol and have more opportunity for imagination, experimentation, and demonstration.

"Strong support of the United Nations and its various specialized agencies such as the World Health Organization represents a fundamental part of United States foreign policy," Mr. Wilcox assured the conference in reviewing the benefits, both indirect and direct, that the United States had derived from WHO's work in raising health standards everywhere. He listed these benefits as the control or eradication of infectious disease at the source, rapid reporting of disease outbreaks almost worldwide, exchange of information and ideas on health and medical advances, the international laboratory networks, and recommendations of common names and standards of purity and potency for drugs and biologicals and the preparation of biological standards.

Secretary Flemming urged that the major contributing nations of the world, including the United States, increase their financial support of WHO. This position was strongly endorsed by Senator Hubert Humphrey, who urged increased contributions, stating that the present total of \$26 million available annually to the Organization (including all sources of funds, not only the regular budget) was not enough even to scratch the surface of WHO's responsibilities. Several speakers contrasted the vast sums spent annually on research and production of weapons for mass destruction with the relatively insignificant amounts devoted to promoting better health throughout the world.

During the conference many suggestions were made concerning the manpower necessary to carry out an effective "health for peace" crusade. Participants in a forum discussion devoted to international medical research emphasized the importance of developing a career pattern which would permit young scientists and teachers to accept assignments in other countries. They suggested collaborative arrangements between universities in the United States and other countries to permit rotating persons as a requisite of career advancement.

Both WHO and the International Cooperation Administration are using regional training centers more extensively, according to Dr. Howard M. Kline, Division of International Health, Public Health Service. He felt that it was best to train candidates in their own countries or in areas where educational traditions, culture, and language are familiar, and that training in the United States was a last choice because our educational centers are adapted to interests and traditions foreign to students from most other countries.

Congressman Judd urged more care in selecting personnel, earlier and more intensive study of languages, and 3-year tours overseas.

Expanding WHO Activities

Looking to the future, a number of suggestions were made for the expansion of international health activities. Secretary Flemming asked for a mobilization of the resources of national and international, official and voluntary agencies in a coordinated plan to accom-

sade could do more to bring peace in our time than any other single program." Senator Eister Hill quoted Dr. Gunnar Gundersen, president of the American Medical Association, to the effect that "medicine with its influence and its resources fully mobilized, can perhaps do more for world peace than all the billions of dollars poured into armaments."

Leo Cherne, chairman of the board of the International Rescue Committee, pointed out, "Medical aid cannot be misrepresented as flowing from self-interest; it cannot be regarded as action remote from the needs of people; it cannot be linked with regimes which may or may not be popular." He added, "When we apply our resources and our talents to the medical needs, the life and death needs of diseased and deprived peoples, we take the final step and one which cannot be misinterpreted."

Cooperation in medical research and in disease control is setting habits and attitudes that "are transferable and will subtly but surely have a beneficial influence on the political climate in the world," stated Assistant Secretary of State Francis O. Wilcox, adding that future historians will credit the present campaigns for the total elimination of disease as among the most remarkable and important achievements of mankind.

Several speakers warned their fellow Americans against attitudes of smugness and self-sufficiency in their relations with some of the lesser developed areas of the world. We have as much to learn from people of other countries as they have to learn from us, stated Dr. Cordier. United Nations technical workers, he said, have found so much individual skill, understanding, and wisdom in the so-called underdeveloped countries that they have come back from their overseas assignments with feelings of great humility and a more realistic perspective of the world.

Brains are not the monopoly of any country, said Congressman Walter H. Judd, who himself spent many years in China as a medical missionary. He pointed out that most of the basic medical discoveries "came from some place where you didn't expect them to come from." This brought up reference to a comprehensive listing of hundreds of medical discoveries in general use today and the geographic

source of their origin, published recently in a U.S. Senate Committee report.

Economic Stake in Health

America's stake in world health was a major subject of discussion at the conference. According to Congressman Judd, those countries with the highest health standards have most to gain from improved world health, and most to lose from diseases that can sweep in from abroad. He reminded his listeners that WHO had, in the past 10 years, checked half a dozen tremendous epidemics "that could have swept over the world including the United States."

Americans must be made to realize the health in the rest of the world is in their own self interest, Senator Richard L. Neuberger stated in support of that thesis. And the American stake in world health is not limited only to the protection of health in the United States, it was pointed out.

One of six forum discussions held during the conference was devoted to health and economic development. Improved health standards are indispensable for any real economic development, it was maintained, since the human resource is the richest economic asset in any country. Poverty-stricken, disease-ridden populations are not a good market for industrial products, and their own output is low and poor in quality.

Mr. Cherne urged that "we recognize that military and economic progress cannot be separated from the physical strength and vitality of any people. Effective economic aid requires a reasonably healthy work force. Viable operation of new industries, no matter how modest, requires a community reasonably free from infection, reasonably capable of applying energy, a community free from unnecessary blindness, debilitating diseases, malnutrition, and a whole variety of ills which affect the stomach, the hands, the limbs, the muscles of men, women, and children of so much of the world."

A related aspect of America's stake in world health was brought out by Dr. Howard A. Rusk, associate editor of the *New York Times*. He maintained that Americans had been paying a 15 percent hidden tax on every article exported to this country from certain maluri-

In so doing, public health lays the foundations of human dignity and self-respect and promotes peace of mind, the basis for harmonious existence within families, groups, and communities.

So conceived, health has a universal projection as part of the efforts of mankind to achieve welfare, peace, and happiness. Gulen said 2,000 years ago, "Health is a sort of harmony."

Constant Interrelationships

Good health, however, does not solve all the problems of welfare. For the progressive evolution of organized communities, human energy of high quality is essential, and this in turn implies an equally high quality of public health. But equally essential is education appropriate to the different periods of life, with a minimum indispensable for all, in order to facilitate adaptation to the environment and thus bring about good human relations. Of no less importance are adequate nutrition, housing, and income; in sum, rational and balanced economic development. It is from such development that will come the production of enough to satisfy the needs of an increasing population.

There is a constant interrelationship among health, economy, and social progress. Experience shows that immediate results can be obtained through organized public health, but the effect will not be lasting unless the other factors which condition well-being are improved simultaneously. It is not enough to maintain a healthy population able to produce and consume, even though it has a sense of responsibility and awareness of common effort to achieve common good. Such a population, constituting a veritable reserve of human energy, demands opportunities for self-realization which can be supplied only by means of well-rounded economic development.

The vicious circle of poverty and disease cannot be successfully broken by attacking disease only. The important thing is to take positive action on all the major factors relating to poverty.

These principles are, in our opinion, the basis for a cooperative effort throughout the Americas to bring about economic development and the welfare of the people in orderly and progressive fashion. To achieve this aim, govern-

ments and the international organizations they have created, supported by individuals and groups in all walks of life, must join together. The urgency of this task is revealed by the present condition of the peoples of the Americas.

Latin America is today the world region which shows the most rapid increase in population. The present rate is almost double the average of other regions, so that the figure of 182 million estimated for 1958 may approximate 592 million by the year 2000. Seventeen of the twenty Latin American countries are expected to double their populations in less than 35 years. Furthermore, this is a young region with 40 percent of its population under 15 years of age. Life expectancy at birth is generally less than 50 years and only in a very few urban communities reaches 60. If to this predominantly youthful population the weight of disease is added, there cannot be enough productive capacity to meet the needs of all.

In these countries infant mortality and child mortality are tragically high, largely because of poor sanitation, prevalence of acute communicable diseases, inadequate nutrition, ignorance, and poverty. The predominance of communicable diseases as the major problem offers great possibilities for organized public health in the Americas, particularly if integrated in a program of economic development.

Water is as important to health as it is to industrial development, yet a water supply in the home is all too uncommon in Latin America. Even in urban areas, at least 30 million people live in dwellings without water; adequate sewage disposal is found even less often. Furthermore, tourism is an important industry in Latin America, and tourism cannot really thrive where water supply and sewage disposal are inadequate and unsafe.

There is still a high proportion of illiteracy, in many of these countries reaching over 50 percent of the population. No community can progress where illiteracy reigns since the people do not have access to sources of knowledge and information.

Latin America has shown in recent years an impressive increase in total production of food, yet, with a rapidly growing population, per capita output has decreased by 6 percent. At the same time, in the great majority of the coun-

plish three health objectives: mass control of preventable diseases, provision of modern health and medical services to the total world population, and advancement of medical science through pooling of knowledge and skills and through development of worldwide research potential.

To accomplish these objectives, Dr. Fleming advocated far greater reliance on WHO than at present. It should be up to the World Health Organization, he said, to set the goals and priorities and to map programs for common action to be carried out cooperatively by international, regional, national, official, and voluntary organizations. He stated further that United States bilateral health programs should be directly related to the attainment of agreed-upon world goals as they are worked out through WHO. "As we as a Nation step up our support of international health, we should shift to a multilateral program as rapidly as this can be done, consistent with our overall foreign policy objectives," Secretary Fleming said.

Senator Humphrey proposed that WHO move more fully into the field of the health aspects of atomic radiation. This is one area, he said, in which WHO will have an unparalleled opportunity for leadership, a leadership in a field which overlaps and overflows the scientific into the political—the area of radioactive fallout. "WHO is uniquely qualified to play a far larger role than at present in securing scientific meeting of the minds as to effects of radioactive fallout on present and future generations," he stated.

Urging a greatly expanded WHO program, Senator Humphrey stated that the existence today of malaria, smallpox, hookworm, yaws, trachoma, and tuberculosis "represents a blot on the conscience of modern man. They are a formidable barrier on the road to any world of progress, peace, and plenty." To cope with this on a really effective scale, he urged the bold mobilization of American resources. WHO should be encouraged and helped, he said, to launch campaigns for the eradication, not only of smallpox, but a whole selection of those diseases amenable to eradication. And WHO should be supplied with the funds necessary to accelerate man's search for answers to

the "battering" diseases such as cancer, heart disease, and arthritis, he said.

The Senator then made a dramatic proposal for the use of food surpluses aimed at breaking the vicious circle of, as he put it, hunger breeds disease—breeds poverty—breeds hunger. Storage costs of surplus foods in warehouses, he said, have amounted to a billion dollars a year, to which should be added another quarter of a billion dollars for the annual cost of deterioration.

Dr. Thomas Parran, former Surgeon General of the Public Health Service and a past president of the National Citizens Committee for WHO, struck a note of optimism for the future outlook when he suggested that although progress toward world health has been substantial, "we may be on the eve of the greatest forward movement in this relatively new type of collaboration and cooperation among peoples that the world has ever seen."—HAROLD BALLOU, consultant, Office of the Surgeon General, Public Health Service.

The Humanistic Relevance Of Public Health

From its beginnings, medicine has evolved as an art based on moral and aesthetic principles, pursuing the knowledge of man as a whole being, both in his physical and spiritual aspects, to assist him in health and disease. As the scientific phase of medicine developed, knowledge of human nature was deepened and the scope of medicine was enlarged. The good physician serves mankind with generosity, sensitivity, and kindness.

Medicine is thus, in essence, humanism—understanding man in historical perspective and social evolution, surrounded as he is by an ever-changing environment. With these objectives, medicine today is both a biological and a social science bearing directly on all the complexities of society, including man's beliefs, traditions, ideas, and ways of living.

For man as a member of society living in a community, community medicine becomes public health. And public health is the expression of man's endeavors to prevent disease, to protect and promote health, and to lengthen life.

Standardization of the crude birth and death rates of the U.S.S.R. indicates that, contrary to the claims, Soviet mortality is higher than that of the United States and its fertility is lower.

Analysis of Mortality and Fertility Data of the Soviet Union

ROBERT J. MYERS

BOTH MORTALITY and fertility are sometimes measured by so-called crude rates. The crude death rate is merely the number of deaths in a year divided by the average total population during the year (or the total population in the middle of the year). Similarly, the crude birth rate is based on the total number of births in the year and the total population. Analysis of these crude rates possesses a certain significance if confined to a single country over a period of a few years, but even here there are certain limitations and dangers. Even greater difficulties, and in some instances insurmountable ones, arise if international comparisons are made. The main reason is the difference in age structures of the basic populations, either in the same country at different times or in different countries.

The following extreme example of the effect of age structure on the crude death rate is indicative of the weakness of this measure for analytic purposes. Consider town A, consisting primarily of a large university, with accompanying service facilities. It would naturally be expected that this town would have a very low crude death rate because most of its residents are young students. On the other hand, consider town B, which because of its favorable warm climate is a haven for retired persons. This town would obviously show a relatively high crude death rate, one much higher than town A, despite the fact that it

might be the "healthier" place in which to live if the population structures were the same.

This paper examines and analyzes the available data on mortality and fertility in the U.S.S.R. In recent years, the data that have been released have been extremely limited. They include only such items as crude birth and death rates, total population, and expectation of life at birth. There are no figures by age for the population or for deaths, births, or expectation of life.

The Soviet Union frequently lays great emphasis on its crude birth and death rates. For instance, its first report on the 1959 census stated that the death rate is the lowest in the world (1). This statement has also been made a number of other times about previously published crude rate figures, despite the fact that the U.S.S.R. has released figures for the expectation of life at birth for recent years that are some 6 percent lower than those of the United States. Similarly, on the basis of crude birth rates, the U.S.S.R. claims a high fertility rate.

World Comparisons of Death Rates

Before analyzing the effect of standardizing the U.S.S.R.'s mortality rates, let us see whether

Mr. Myers is chief actuary, Social Security Administration, Department of Health, Education, and Welfare.

tries, the consumption of protein of animal origin is far below the physiological minimum.

The housing problem in Latin America is proverbial. In large areas houses are completely inadequate, and the amount of construction does not keep pace with the normal increase of the population.

As a corollary of all this several countries are undergoing serious inflation, with increasing cost of living, which further reduces an income already insufficient for basic needs.

Economic Roots

At the root of the entire process of development are the economic conditions. Cultivation of arable land in Latin American countries is limited to 4 percent of the total surface. There is an acute insufficiency of capital. Industrial development is in its beginnings and exports are limited. Production is not sufficiently diversified, and all too often countries depend on a single product. Geography is difficult, with large rural areas and inadequate means of communication and transportation, which often make access to resources impossible. If one adds the constant increase of population, it is easy to understand the high rate of unemployment.

Although there is sufficient knowledge to cope with most of the major public health problems of the Americas, the number of trained professional and auxiliary personnel is inadequate. Besides the insufficiency of material resources, local and national health services do not have adequate organization to obtain the best possible yield from the available personnel and resources.

In spite of these shortcomings, progress has been and will continue to be substantial, and the efforts of the governments, with the assistance provided by international organizations, have major accomplishments to their credit.

The World Health Organization and the Pan American Health Organization are actively collaborating with the member governments in strengthening national and local health services, in training professional and auxiliary personnel, in controlling or eradicating acute and chronic communicable diseases, and in searching for new methods for the protection and promotion of health.

The greater the progress toward elimination of pestilence, the clearer becomes the relationship between health and economic progress.

The basic activities in public health, those which further optimal human growth and development by diminishing risks stemming from the physical and social environment, require good planning and organization, well-trained personnel, and large amounts of capital. In the present stage of Latin American growth this capital can be obtained by cooperative measures among all the governments, through a carefully planned and progressive program. The creation of the Inter-American Bank for Development and the current discussions about a common market are excellent indicators of the desires motivating the governments of the Americas. When combined with other similar steps, these measures will clearly serve to improve the living conditions of the people of our hemisphere, while respecting their ideals and individual cultures.

Because this development is so consistent with the philosophy expressed in the constitutions of the World Health Organization and the Pan American Health Organization, it seems to me inevitable that public health activities will be a major aspect of the balanced plan for economic progress which I foresee.

Our countries are passing through a phase of destiny which calls for genuine merging of forces to face the major problems of today and tomorrow. But we must always keep before us that our ultimate aim is the welfare of mankind.

The moment in which we live is a real challenge to fate which needs to be expressed in simple and direct terms and requires equally simple and direct answers.

We health workers believe that we have shown what international collaboration can do to give incentive to progress. We offer this experience in order to help find the answers so badly needed in the world today. We do so with the conviction that in fighting for health we are fighting for peace.—ABRAHAM HORWITZ, M.D., *director of the Pan American Sanitary Bureau, Regional Office for the Americas of the World Health Organization.*

of a given standard to the age-sex distribution of the particular population under study. The deaths "expected" on the basis of the mortality standard can then be obtained. The standardized crude death rate can be computed for these "expected" deaths and then compared with the actual crude rate. The comparison indicates the relative level of the actual mortality of the population as against that of the mortality standard.

For analysis of the mortality experience of the U.S.S.R. in 1956, the actual experience of the United States in the same year is used as the mortality standard (7a). (Rates for the age group 0-4 years were modified because of the theoretical consideration that the number of births each year in the past 5 years in the United States would not necessarily have the same pattern as in the U.S.S.R. The difference, however, has relatively minor effect on the results as a whole.)

Table 1 sets forth the basic data used in the analysis and also the estimate of deaths that would have occurred in the U.S.S.R. population if U.S. mortality had applied. The resulting crude death rate is 6.18 per 1,000 (1,231,300

deaths divided by 199,336,000 population), or 20 percent below the reported U.S.S.R. rate of 7.7 per 1,000. This is a very low crude death rate and is due to the Soviet Union having a very young age distribution. The age-specific U.S. death rates when applied to the U.S. age distribution in 1956, of course, yield the previously mentioned crude death rate of 9.6 per 1,000, 25 percent above the reported Soviet crude rate, but 55 percent above what the Soviet crude rate would have been if that country's age-specific rates had been equal to those of the United States. The relatively young age distribution in the U.S.S.R. may be seen from the fact that only 7.8 percent of its population is aged 60 years and over as against 12.6 percent in the United States in 1956 (and about 20 percent for a stationary life table population based on current U.S. mortality and a constant annual number of births). The relatively low crude death rate currently reported by the U.S.S.R. is thus clearly due in considerable part to its relatively young age distribution.

Calculations standardizing mortality similar to those in table 1 have also been made for the U.S.S.R. for the officially reported age-sex dis-

Table 1. Application of U.S. mortality rates to U.S.S.R. population, Jan. 1, 1956

[Population and deaths in thousands; rates per thousand]

¹ Reference 5. Subdivision of data for ages 70 years and over from unpublished data of the U.S. Bureau of the Census.

² Reference 7a, except that rates for age group 0-4 years are based on values obtained from abridged life tables (with weighting by relative proportions of white and nonwhite populations in this age group).

the reported crude death rate of the Soviet Union is the lowest in the world. The figure was 7.7 per 1,000 for 1956, which was definitely below the corresponding figure for the other major industrially developed countries in the world, such as Australia, Canada, New Zealand, the United States, and the Western European nations, most of which had crude death rates of from 8 to 12 per 1,000 (2a). On the other hand, there were a number of countries that had lower crude death rates than the Soviet Union: Greece (7.4), Iceland (7.2), Iran (6.8), Israel (6.6), Lebanon (5.5), Peru (6.8), Syria (5.4), and Uruguay (7.0). Many of these countries are not particularly noted for their favorable health or economic conditions. Probably the reason for the low crude death rates of these countries lies in the dual circumstances of a relatively young age distribution and the very significant postwar reductions in certain communicable diseases. Also, in some of these countries the accuracy of reporting of deaths and enumeration (or estimate) of the population may be questioned.

In 1956 certain outlying U.S. possessions and territories had lower crude death rates than the U.S.S.R.: Alaska (5.8), Guam (6.6), Hawaii (5.8), Puerto Rico (7.0), and Samoa (7.4). A number of small possessions of European nations, such as Angola, Cyprus, Fiji Islands, and Sarawak, also had very low crude death rates.

Trends in Crude Death Rates

The only official Soviet data on mortality for the last 30 years are crude death rates and infant mortality rates. Eliminating periods of war and civil strife, the decline in the crude death rate has been striking, from 30.2 per 1,000 in 1913 to 20.3 per 1,000 in 1926, to 18.3 per 1,000 in 1940, and then to 9.6 per 1,000 in 1950, followed by a steady decline each year thereafter to 7.7 per 1,000 in 1956 (3a). These figures are indicative, to a certain extent at least, of a real improvement, but how much the decline in mortality is due to improved health and how much to changes in age structure is a question.

Similar declines in the crude death rate occurred in other countries that had relatively

high levels of mortality before World War II. In Japan, for example, the crude death rate was 19.4 per 1,000 in 1913 and 19.2 per 1,000 in 1926, and declined to 16.2 per 1,000 in 1940, to 10.9 per 1,000 in 1950, and then to 8.0 per 1,000 in 1956 (2a, 4). Thus, the trend of the crude death rate in the period immediately preceding World War II and thereafter has been very similar in Japan and in the U.S.S.R.

The United States had a much lower level of mortality before World War II than the U.S.S.R. or Japan. Accordingly, although there was a significant improvement in mortality in the past half century in the United States, the crude death rate had a much smaller decrease than in many other countries. Thus, the U.S. crude death rate was about 14 per 1,000 in 1915. Over the next 40 years, in general, it declined gradually to a level of 9.6 per 1,000 in 1956. The actual improvement in health conditions was even greater than this because the age structure of the population shifted to a much older age distribution.

Standardization of U.S.S.R. Mortality Data

No recent information on deaths in the Soviet Union by age and sex is available. Without such data the only possible method of analyzing mortality experience is by standardization. The results achieved are not too informative, since it is desirable to analyze the experience by age and by sex in order to determine the true significance of any changes. But, in the absence of complete data, the standardization procedure is certainly better than no analysis at all.

The method of standardization requires that the age distribution of the population be available even though that for deaths is not. The Soviet Union has not released figures about the age distribution of the population since the 1939 census. However, detailed estimates for 1956 have been prepared by the U.S. Bureau of the Census (5) and also by an eminent French demographer (6). Although the two sets of figures differ somewhat, the resulting standardized death rates (and birth rates) differ by less than 3 percent.

The method of standardization is to apply the age-specific mortality rates, separately by sex,

thereafter in such manner as to give age-specific mortality rates that reproduce exactly the Soviet crude rate of 7.7 per 1,000 when they are applied to the 1956 age-sex distribution.

The age-specific mortality rates shown by U.S. experience were uniformly increased by 24.6 percent for the first assumption; for the second assumption, by 78 percent for age 0, 77 percent for age 1 year, decreasing by 1 percent for each year until there is no differential for ages 78 years and over. This latter treatment produced a crude death rate of 7.72 per 1,000 for the 1956 age-sex distribution and was adopted because of its simplicity (rather than beginning at 80 percent at age 0 and then working down to a zero differential in a more complex fashion). The U.S. age-specific mortality rates were developed from the complete life tables for 1956 prepared by the Metropolitan Life Insurance Co. from the official abridged life tables for 1956 (2b), which are for all persons and for each sex by race. The author developed therefrom corresponding tables for all males and all females, using also the official abridged tables for these two categories (unpublished data from the National Office of Vital Statistics).

The expectations of life at birth were then computed from the life tables developed from such age-specific rates. The results of these computations of expectation of life at birth for 1956 are shown in the following table, in comparison with the reported Soviet data for 1955-56:

Category	Reported figures	Computed figures	
		Constant differential	Decreasing differential
All persons---	67	66.5	65.7
Males-----	63	63.3	62.3
Females-----	69	70.0	69.5

The male and female figures obtained by assuming a constant mortality differential with age between U.S.S.R. and U.S. experience are actually somewhat above the reported values. However, the male and female figures based on a decreasing differential (starting higher and ending lower), which are probably the more logical, are reasonably close to the reported values. The reported figure for both sexes

combined is higher than the two computed values, but this has no significance because of the excess female population in comparison with what would be expected in a life table population.

Trends in Crude Birth Rates

Soviet data on fertility are as sparse as they are for mortality. The only official figures available are crude birth rates, the trend of which has been just as strikingly downward as that of the reported death rates. Thus, the reported crude birth rate was around 45 per 1,000 in both 1913 and 1926 and fell to 32 per 1,000 in 1940. In the 1950's, this rate has been relatively level at 25 to 27 per 1,000, with the 1956 figure being 25.0 (3a).

The trend and level of the crude birth rate in most of the industrialized and well-developed countries in the past half century (2b) have been somewhat different from the pattern in the U.S.S.R. In general, there was a steady decline until about 1940. In the 1950's, in most countries, the level has been definitely higher than that in the 1930's. However, in some countries (for example, Austria, Denmark, the Netherlands, and the United Kingdom) the level is about the same as in the 1930's and in a few, primarily in the Mediterranean area, the current level is lower than in the 1930's, just as in the U.S.S.R.

In the United States, the crude birth rate dropped from about 30 per 1,000 in the 1910's to a low of about 19 in the 1930's. Since World War II it has been about 25 per 1,000. In most of the Western European countries, the crude birth rate has been somewhat lower than in the United States, but with the same general trend: currently, the rates in these countries are about 16 to 22 per 1,000. Canada, too, has had about the same trend in the crude birth rate as the United States, but the level has generally been about 10 percent higher. In Japan, which has had somewhat the same trend in the crude death rate as the Soviet Union, the crude birth rate has displayed an entirely different trend from that of the U.S.S.R. (or for that matter, different from that in any other major country). The rate was level at about

tribution of the population in 1926 and for the estimated age-sex distribution in 1939. The estimate for 1939, prepared by Michael K. Roof, Legislative Reference Service, Library of Congress, is based on the officially reported census distribution by broad age groups (under 7, 8-11, 12-14, 15-19, decennial age groups up to 60, and 60 and over), supplemented by sex breakdowns from literacy data and by projections to 1939 of the 1926 census data and of data on subsequent births.

The mortality standards used for the 1926 and 1939 population distributions are the actual age-specific death rates, by sex, for the United States for the same years. For 1926, the U.S. age-specific death rates are available only for certain age groups (under 1, 1-4, decennial age groups up to 85, and 85 and over); therefore, the Soviet census data were grouped accordingly. For 1939, the U.S. age-specific death rates are available for the following age groups (unpublished data from the National Office of Vital Statistics): under 1, 1-4, quinquennial age groups up to 85, and 85 and over. The estimated Soviet age distribution for 1939 is available in similar groups except that ages 70 and over are combined, but breakdown into quinquennial groups has been made by assuming that the proportionate distribution of the population aged 70 and over in 1939 was the same as in 1926.

The resulting standardized crude death rates are compared with the reported crude death rates of the U.S.S.R. for closely corresponding periods in the following table:

Year	Crude death rate	Standardized death rate	Excess of crude over standardized rate (percent)
1926---	20.3	11.87	71
1940----	18.3	8.71	110
1956-----	7.7	6.18	25

The excess of the reported U.S.S.R. crude death rate over the standardized crude death rate based on U.S. experience has decreased very significantly in the past three decades, although immediately before World War II it was more than 100 percent and it still amounts to 25 percent. This change would seem to indicate that

there has been a very significant improvement in mortality in the Soviet Union in recent years, according to the reported crude death rates.

U.S.S.R. Data on Life Expectancy

Although no Soviet data on mortality experience by age have been released in the past three decades, figures have been published as to the expectation of life at birth (3*b*, 8). These, along with corresponding figures for the United States (9*a*), are as follows:

Period	All persons		Males		Females	
	U.S.S.R.	U.S.	U.S.S.R.	U.S.	U.S.S.R.	U.S.
1926-27----	44	58.6	42	57.2	47	60.0
1954-55----	64	69.6	61	66.7	67	72.9
1955-56----	67	69.6	63	66.7	69	73.0

The reported improvement in the expectation of life at birth in the U.S.S.R. in the last three decades is very significant. Although the U.S.S.R. rate of improvement has been greater than that of the United States, the latter still shows a significantly higher expectation, by 3.7 years for males and 4.0 years for females. Interestingly, the difference is only 2.6 years for both sexes combined, which is the result, in large part, of the higher proportion of women in the U.S.S.R. than in the United States (the 1956 sex ratios of the total population were 887 and 984 men per 1,000 women, respectively). This comparison demonstrates why it is desirable to consider mortality experiences separately by sex.

The data on expectation of life at birth in the U.S.S.R. for 1955-56 can be analyzed, to a certain extent, on the basis of the standardization analysis previously made. This indicated that, in the aggregate, Soviet mortality in 1956, when standardized by age and sex, was 24.6 percent higher than U.S. mortality for the same period. It may first be assumed that this difference applies at each age, although this is almost certainly not the case. Since the infant mortality rate in the Soviet Union was reported as 47 per 1,000 in 1956 (10), or about 80 percent higher than that of the United States for the same year, another possible approach is to assume a graded differential that is about 80 percent at age 0 and that decreases

order, showing the ratio of children of a particular birth order to total children:

Birth order	U.S.S.R. (percent)	U.S. (percent)	Ratio U.S. to U.S.S.R. (percent)
1 -----	8.6	11.1	129
2 -----	4.6	5.8	126
3 -----	2.5	3.2	128
4 and higher -----	2.2	5.0	227
Total -----	17.9	25.1	140

The higher birth orders in the United States are clearly more prevalent than in the Soviet Union. This finding confirms the results of the other analyses; that is, that fertility is significantly higher in the United States than in the U.S.S.R.

Summary and Conclusions

The Soviet Union frequently makes the claim that its mortality is the lowest in the world, whereas in the past it was extremely high. These statements are made on the basis of the crude death rate, which is currently reported at a relatively low level, for 1956 some 20 percent lower than the United States. However, the Soviet Union has also reported figures for the expectation of life at birth, which, for 1956, are about 4 years lower than for the United States, for both men and women.

Similarly, the only figures available as to fertility are the crude birth rates. On the basis of these, the U.S.S.R. claims a high fertility rate. Actually, in recent years, the Soviet crude birth rate has been well above that of most Western European countries, but virtually the same as for the United States.

This paper has analyzed mortality and fertility in the U.S.S.R. on the basis of standardization by age. This procedure is especially necessary in dealing with data for the Soviet Union because of the unusually young age distribution of the population. The resulting analysis indicates that Soviet mortality as reported, after taking into account age and sex distributions, is about 25 percent higher in the aggregate than that of the United States, while fertility is about 24 percent lower.

Analysis tends to confirm to a considerable extent the reliability of the reported Soviet figures on expectation of life at birth, assuming the accuracy of the reported crude death rates. The differential in life expectancy between the United States and the U.S.S.R., for each sex, currently amounts to about 4 years (in favor of the United States).

Considerable improvement in mortality in the U.S.S.R. has undoubtedly occurred since the pre-World War II period. This same trend, however, has been present in many other countries throughout the world that had relatively high mortality in the past.

33 per 1,000 from the turn of the century to the beginning of World War II and for a few years thereafter (4), but then it declined sharply to about 18 per 1,000 in 1956.

The current level of the Soviet crude birth rate is thus relatively high as compared with that of other major industrialized countries, although not high in comparison with many of the underdeveloped countries, which have rates as high as 40 to 50 per 1,000. But this high crude rate is not necessarily an indication of high fertility in the U.S.S.R.

Standardization of U.S.S.R. Fertility Data

Just as mortality is sometimes erroneously measured by the crude death rate, it is not uncommon to see measurement of fertility attempted through the use of the crude birth rate. Here, too, proper analysis requires at least age-specific fertility rates (births to mothers of a given age, divided by total women in the population in that age group), and more adequate analysis can be made if consideration is given also to marital status and birth order.

When, however, data on births by age of mother are not available, but rather only the total female population by age groups is at hand, the only possible analytical procedure is standardization. If data were available by marital status and birth order, further standardization could be done. But, in any event, standardization by age is of some significance.

The method of standardization of crude birth rates is the same as described for crude death rates, except that only the female population is considered.

Actual experience of the United States in 1956 has again been used as the standard (7b). The basic data of this analysis and also the estimated births that would have occurred in the U.S.S.R. population if U.S. fertility had applied are shown in table 2. The resulting crude birth rate is 32.69 per 1,000 (6,516,400 births divided by 199,336,000 population), or 31 percent above the reported U.S.S.R. rate of 25.0 per 1,000. The relatively young age distribution of the U.S.S.R. population is clearly responsible, in considerable part, for the moderately high crude birth rate currently reported by that country. It may also be inferred that,

Table 2. Application of U.S. fertility rates to U.S.S.R. population, Jan. 1, 1956

[Population and births in thousands; rates per thousand]

Age group (years)	U.S.S.R. female population ¹	U.S. 1956 fertility rates ²	Estimated U.S.S.R. births
10-14-----	7,685	1.0	7.7
15-19-----	10,653	94.2	1,003.5
20-24-----	8,057	251.3	2,024.7
25-29-----	10,096	195.5	1,973.8
30-34-----	8,573	116.4	997.9
35-39-----	6,359	60.3	383.4
40-44-----	7,452	15.9	118.5
45-49-----	6,918	1.0	6.9
Total-----	65,793	-----	6,516.4

² Reference 7b.

on the whole, fertility in the Soviet Union is 24 percent lower than in the United States.

U.S.S.R. Fertility and Family Allowances

Another indication of the level of U.S.S.R. fertility may be found in data from the country's family allowance program. Under this program, monthly payments are made to children aged 1 through 4 years who are of fourth or higher order of birth, the amount varying according to the birth order. At the end of 1956, 3,312,000 children were reported to be receiving such allowances, representing 17.9 percent of children in the country aged 1-4 years, as estimated by the author on the basis of data on total population and births presented by Biraben (6). The corresponding figures for the end of 1950 were 3,079,000 children receiving allowances, representing 19.2 percent of the children aged 1-4 years.

Although census data on children by birth order are not available for the United States, adequate and proper analysis can be made by considering birth-order data reported to the National Office of Vital Statistics. For 1953-56, births of the fourth and higher orders were 25.1 percent of all births in the United States, significantly higher than in the Soviet Union. The following table compares the figures for the two countries, with subdivision by birth

order, showing the ratio of children of a particular birth order to total children:

Birth order	Ratio U.S. to U.S.S.R.		
	U.S.S.R. (percent)	U.S. (percent)	U.S.S.R. (percent)
1 -----	8.6	11.1	129
2 -----	4.6	5.8	126
3 -----	2.5	3.2	128
4 and higher -----	2.2	5.0	227
Total -----	17.9	25.1	140

The higher birth orders in the United States are clearly more prevalent than in the Soviet Union. This finding confirms the results of the other analyses; that is, that fertility is significantly higher in the United States than in the U.S.S.R.

Summary and Conclusions

The Soviet Union frequently makes the claim that its mortality is the lowest in the world, whereas in the past it was extremely high. These statements are made on the basis of the crude death rate, which is currently reported at a relatively low level, for 1956 some 20 percent lower than the United States. However, the Soviet Union has also reported figures for the expectation of life at birth, which, for 1956, are about 4 years lower than for the United States, for both men and women.

Similarly, the only figures available as to fertility are the crude birth rates. On the basis of these, the U.S.S.R. claims a high fertility rate. Actually, in recent years, the Soviet crude birth rate has been well above that of most Western European countries, but virtually the same as for the United States.

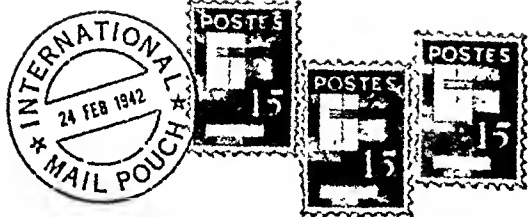

This paper has analyzed mortality and fertility in the U.S.S.R. on the basis of standardization by age. This procedure is especially necessary in dealing with data for the Soviet Union because of the unusually young age distribution of the population. The resulting analysis indicates that Soviet mortality as reported, after taking into account age and sex distributions, is about 25 percent higher in the aggregate than that of the United States, while fertility is about 24 percent lower.

Analysis tends to confirm to a considerable extent the reliability of the reported Soviet figures on expectation of life at birth, assuming the accuracy of the reported crude death rates. The differential in life expectancy between the United States and the U.S.S.R., for each sex, currently amounts to about 4 years (in favor of the United States).

Considerable improvement in mortality in the U.S.S.R. has undoubtedly occurred since the pre-World War II period. This same trend, however, has been present in many other countries throughout the world that had relatively high mortality in the past.

Milk Week

Milk Week for all Ceylon ended on Independence Day, February 4, 1959, with 2,500 school children marching in a parade and pageant in Colombo. Approximately 70,000 people saw a physical education demonstration and floats in Independence Square. Similar demonstrations were held in other parts of the island.

During Milk Week schools held poster competitions and exhibited health and nutrition work. Posters, film shows, radio, and newspaper stories focused public attention on the value of milk and its availability through CARE in the schools.

The celebration was part of a long-range effort to improve nutrition in schools and homes and to encourage use of home and school gardens.

—PHILIP RILEY, *public health education adviser, U.S. Operations Mission, Ceylon.*

Training Medical Students

Quinta Normal Health Center will serve as a demonstration teaching center for medical students and as a demonstration of a comprehensive integrated health program. Chile's National Health Service has assigned a section of the center's building to the Medical School of the University of Chile for carrying out this project of the school's division of preventive medicine and public health.

The medical school will assume responsibility for the health of 2,000 families in one area served by the center. Two pediatricians, an internist, and a psychiatrist from the school; and two pediatricians, an internist, an obstetrician, two nurses, and two social workers from the National Health Service will staff the project.

When a birth occurs in a family living in the area, the mother and child will be given maternal and child health services, and, through them, the rest of the family will be reached. As they provide hospital, outpatient, and home care, medical students will learn about social and economic as well as medi-

cal and public health problems. Students are responsible for specific families during their studies in preventive medicine and public health.

—G. HOWARD GOWEN, M.D., *chief, division of preventive medicine and public health, U.S. Operations Mission, Chile.*

Courses for Rural Physicians

Nearly 300 rural physicians have taken postgraduate courses at the Institute of Rural Occupational Medicine and Rural Health in Lublin, Poland. The 3- or 4-week courses were started in 1952 after investigations revealed that rural physicians had inadequate training in sanitary and preventive methods.

The institute offers a course stressing hygiene and prophylaxis, a general clinical course emphasizing traumatology and the more common diseases of the rural environment, a course in laboratory and X-ray techniques, and a course in internal medicine and pediatrics focused on diseases associated with rural living and working conditions.

The institute has planned the curriculum for a fifth course, which deals with epidemiology and the anthroponozoonotic diseases, to be offered to physicians and veterinarians, and hopes to start courses for rural nurses and rural health instructors.

Some 300 rural physicians as well as many scientists and specialists in rural health service organizations attend the annual nationwide conference of rural practitioners organized by the institute. Since 1957 the section of rural medicine of the Polish Medical Society has assisted in organizing these conferences.

—DR. Z. KAWECKI, *chief, methods organization section, State Institute of Rural Occupational Medicine and Rural Health, Lublin, Poland.*

Fluoridation

Public water supplies are being fluoridated, as a dental health measure, in Penang (234,000 population), Federation of Malaya, and in the State of Singapore (1,467,000 population). Fluoridation has been approved also for the public water supply of Hong Kong (2,600,000 population).

—DR. A. KARIM, *assistant director of medical services (dental), Ministry of Health, Federation of Malaya.*

By Leroy E. Burney, Surgeon General,
Public Health Service, August 28, 1959

Live Poliomyelitis Vaccine Status

The present status of attenuated live poliovirus vaccines has been reported by the Public Health Service's Committee on Live Poliovirus Vaccine, headed by Dr. Roderick Murray, chief of the Service's Division of Biologics Standards.

The committee has reviewed the rapidly accumulating data on the development and field use of attenuated live poliovirus vaccines and has considered the initial problems involved in the preparation of provisional specifications for their production. It has been given responsibility for evaluating all available information, for determining what additional information is needed, and, where necessary, for initiating studies to supply the answers to questions that must be resolved before licensing can be recommended.

If energetic efforts are continued to find answers to the remaining technical questions concerning safety, effectiveness, and manufacturing procedures, one or more of the three vaccines now being proposed may be under production within 1 to 2 years. Meanwhile, in the Salk vaccine there already is at hand a potent weapon whose value and effectiveness have been proved. I continue to urge all persons, particularly those under 40 years of age, to complete their series of Salk injections so that no one will remain unprotected at the time of the next poliomyelitis season.

The status of live poliovirus vaccine as reviewed by the committee follows:

1. Three sets of attenuated poliovirus strains have been proposed for use as oral vaccines. The Sabin strains (Dr. Albert Sabin, University of Cincinnati) have all had extensive field trials in Eastern Europe, Mexico, and Singapore. The Lederle strains (Dr. Herald Cox,

Lederle Laboratories) have been widely used in Latin America. The Koprowski type 1 strain (Dr. Hilary Koprowski, Wistar Institutes, Philadelphia) has been used in a large trial in the Belgian Congo. However, no significant amount of field information is available concerning Koprowski's type 2 strain, and only limited information is available in relation to his type 3 component.

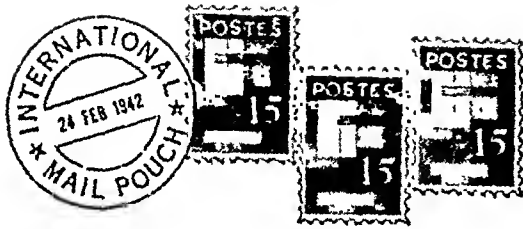

2. There is considerable difference in the neurovirulence or damaging effect on nerve cells for monkeys of the three sets of strains as determined by intrathalamic and intraspinal inoculation. On this basis, the Sabin group has an advantage over the others, but none of these strains is completely nonvirulent when inoculated into monkeys by the intraspinal route.

3. No evidence has been reported to indicate that any of these vaccines produced any harm to the individuals to whom they were administered. The thoroughness with which the observations were made has varied in different studies.

4. In some studies the ability of these strains to multiply and thus produce antibodies is less than could be expected on theoretical grounds. Apparently a number of factors operate in the field which may prevent alimentary infection and the subsequent development of immunity.

5. A number of workers have reported that virus excreted by vaccinated individuals has shown increased neurovirulence for monkeys. There is considerable disagreement among investigators as to the significance of these reversions in virulence.

6. Field experience with any strain to date cannot be interpreted as affording reasonable

Courses

for

Nursing Home Personnel

The advent of chronic and degenerative diseases as major health concerns has ushered in an era in medical care that requires, more than ever before, the personal and active cooperation of many persons. Often these people have the desire and ability to participate in caring for the senior citizen but do not possess the skills required to do so.

Since the fundamental goal in public health is to make available the best health protection and guidance to all, health departments have a role in the training of people caring for the chronically ill and aged. Throughout the country various State and local health departments have assumed this responsibility and are offering training courses for nursing home personnel.

As a contribution to this effort, *Public Health Reports* has assembled three articles dealing with some of the techniques that may be used in training personnel to care for the chronically ill and aged in nursing homes and homes for the aged.

The techniques described in these articles are not panaceas. They merely represent three approaches to training that are being tried. It is sincerely hoped that they will be of assistance to those who are interested in training personnel for nursing homes and homes for the aged.

proof that the community of nonvaccinated persons will be free of danger from possible reversion of virulence in excreted virus under a great variety of readily anticipated circumstances. This is one of the most important unresolved problems.

7. There is evidence which indicates that under some circumstances the simultaneous administration of all three types of virus may be effective.

The committee reported the following major problems which remain to be solved before definitive decisions can be made regarding licensing:

1. The significance of increased neurovirulence for monkeys of virus excreted by vaccinated individuals.

2. The demonstration of adequate measures of effectiveness of live poliovirus vaccines in field trials which, to be definitive, must involve

large population groups. The capacity of the virus to spread among contacts means that in such a controlled field trial some nonvaccinated controls will become infected and thus presumably become immune—a complicating factor in such a study.

3. The development of standards to determine the possible presence or absence of stray agents in the vaccine. More than 40 simian agents, including B virus, have been encountered in the routine testing of killed poliovirus vaccine. These are derived from the monkey tissues used. Little is known of their pathogenicity for man except B virus, and even for this the minimum infecting dose is not known.

4. The establishment of carefully designed and evaluated studies to demonstrate the production of specific antibodies in 90 percent or more of inoculated susceptibles in order to assure the potency of such vaccines.

First 20 Years of the Crippled Children's Program

The number of handicapped children served annually by the crippled children's program of the Children's Bureau increased from 110,000 in 1937, when the program began, to 313,000 in 1957.

Between 1950 and 1957, the number of children who received care and treatment for epilepsy alone increased 387 percent. According to the Children's Bureau, changes in the attitude of the public toward epilepsy coupled with drugs which now can largely control epileptic seizures have made it possible for more and more children so handicapped to become contributing members of society. Those treated for eye conditions increased 234 percent, for diseases of the nervous system and sense organs, 162 percent, and for congenital malformations, 80 percent.

In 1950, only about 2,200 children with congenital heart malformations received serv-

ice in the crippled children's program. By 1958 because of rapid developments in diagnosis and treatment of congenital heart disease, more than 12,000 such children were helped.

At the same time, the crippled children's program is helping to establish and expand programs for services to child amputees. The Bureau has received reports from 30 States which show that they have slightly more than 2,000 children who lack one or more limbs or parts of limbs, and who can benefit from prosthetic devices and training.

At the beginning of the crippled children's program, children stayed in the hospital an average of 43.6 days. In 1957, they were staying an average of 24.4 days. From 1945 to 1957, the average cost per hospital-day went up almost 200 percent, from \$8.95 in 1945 to \$26.81 in 1957.

from the manual, the rapid training method of teaching was used to instruct 51 administrators and 133 nursing aides from 71 homes during the project period (January 1-December 31, 1958). After the study was completed the State continued the course, and an additional 186 aides and 55 administrators have been trained. In 1958 Oklahoma had 554 licensed nursing homes with a total of 7,738 beds employing an estimated 1,200 nursing aides but only 14 graduate registered nurses and 35 licensed practical nurses. The division of public health nursing of the Oklahoma State Department of Health administered the pilot study, and an appointed State advisory committee assisted at the State and local levels.

The Public Health Service has also helped nine other States in developing nursing aide programs. In two of the States registered nurses received instruction in the rapid training method of teaching in teacher-training workshops.

The rehabilitation training program for nursing home personnel being conducted in Illinois under joint Federal, voluntary, and State auspices is an outstanding example of what can be done in inservice instruction. Through intensive training for all personnel in the nursing home this project is endeavoring to ascertain whether effective rehabilitation services can be given to the chronically ill and aged in a nursing home setting. (See pp. 989-994.)

In the Illinois program, a training team composed of two rehabilitation nurses and one occupational therapist goes into the nursing home and works with the staff demonstrating and teaching the techniques to be employed in caring for patients. The team works in the home for approximately 2 months, giving a 1-hour lecture and 7 hours of demonstration daily. The Peoria Institute of Physical Medicine and Rehabilitation provides medical direction.

In evaluating this project one should consider first that it is directed toward a concept and not toward a particular group of employees. Every person working in the home, including the administrator, participates.

Second, it is primarily a teaching and training enterprise, although it does include some patient care. It was considered desirable that

Red Cross Helps Train Nursing Home Aides

Authorized instructors in the Red Cross home nursing program will train paid nursing home aides employed in nursing homes, according to an agreement concluded by the Public Health Service with the American National Red Cross and the American Nursing Home Association.

This cooperative program will be an additional resource for public, private, and nonprofit nursing homes throughout the United States in their efforts to train nursing aides in order to improve the care of their patients.

Nursing home operators are also permitted to take the course since many give nursing care. Because they are administratively responsible for patient care they need familiarity with nursing procedures.

Course enrollments may range from 10 to 14 students, the hours for each course from 20 to 30 hours, and the course content will be adapted to the nursing home situation after the instructor visits the home.

For the students, the textbook is "How To Be a Nursing Aide in a Nursing Home," by Dorothy E. Reese of the Public Health Service; and for the instructor, the guide is "Care of the Sick and the Injured," published by the American Red Cross.

the personnel be trained in the environment where they worked and where the techniques that would be most effective in each home could be adapted and adjusted to the needs of the patients in the specific home.

The program has achieved excellent results and has been enthusiastically received by the participants. Other States are considering similar programs.

Many States have found it desirable to work with all the personnel providing care in nursing homes rather than just with nursing aides. In these States it was felt that only through educating the entire staff in certain basic concepts could the best results be obtained.

An important factor in the success of all three types of instruction has been the interest and enthusiasm of the local physicians, nurses, therapists, and others directly and indirectly caring for patients. It is they who will carry

Filling Training Needs

BRUCE UNDERWOOD, M.D.

THE LACK of trained personnel is not unique to nursing homes. Perhaps the shortage appears to be more pressing in this than in other health fields because of the great increase in the number of nursing homes in recent years.

What are the facts that highlight this shortage?

There were approximately 25,000 nursing homes containing 450,000 beds in the United States in 1954. Some 7,000 homes were in the skilled nursing home category. The average age of nursing home residents was 80 years, and about half of them were severely incapacitated in one way or another.

Of the 66,000 persons the homes employed to care for these ill and disabled persons, 39,000 could be classified as full-time nursing personnel who performed tasks requiring nursing skill of one kind or another. About 15,000 were either full-time registered nurses or licensed practical nurses. About 60 percent were nursing aides who have received little or no formal training. Only one-third of the homes have either a registered nurse or a licensed practical nurse on their staff.

These figures show that the present staffing of nursing homes with registered nurses and licensed practical nurses is inadequate. We must also realize that, generally, the nursing aides have not been trained as they should be.

Nor will the need for training become less

important. If present projections bear out, we can expect our aging population to number more than 21 million by 1970, and 5 percent of them will require institutional care of one sort or another. Not only will the number of older people increase but their demands for institutional type care can be expected to grow, as insurance and other methods of payment for such care increase. Also, the trend toward living in small homes and apartments will cause more elderly citizens to seek institutional care, since they are unable to live with relatives, as many have in the past.

The problem is twofold; first, to obtain personnel to meet the increasing demands being placed on nursing homes for care, and second, to train them. At present, there is recognition that at least three types of instruction may be applicable in training nursing home personnel: accredited courses in vocational and other educational institutions; special workshops, institutes, and training sessions at central locations outside the nursing home; and training within the home.

Many States have found that the first type of instruction is effective in training licensed practical nurses, food service managers, and other similar personnel.

An example of the second type is a pilot study conducted by the Chronic Disease Branch, Public Health Service, and the Oklahoma State Department of Health to test the effectiveness of the manual entitled "How to be a Nursing Aide in a Nursing Home." This handbook was developed by the Division of Nursing Resources, Public Health Service, published in 1958, and is being distributed by the American Nursing Home Association.

With subject matter for the course drawn

Dr. Underwood is nursing home consultant, Chronic Disease Branch, Division of Special Health Services, Bureau of State Services, Public Health Service. The article is based on a speech given at the annual meeting of the Kentucky State Association of Nursing Homes in Lexington, April 29, 1959.

Instructing Nursing Home Personnel in Rehabilitation Techniques

JOHN A. HACKLEY

IN ILLINOIS, as in most other States, complete and intensive rehabilitation services are limited to a few urban areas, notably Chicago and Peoria. Elsewhere in the State public and private nursing homes are expanding rapidly to care for chronically ill and disabled persons. Some of these persons at other times and under other circumstances would have been hospital patients. But hospital care for such patients is frequently inappropriate, unavailable, or economically prohibitive, or no agencies are available to help them obtain hospital care.

In many sections of Illinois hospital care is not available in the patient's community, and the local physician must rely upon the nursing home for inpatient care when care at home cannot be provided. The shrinking size of private dwellings and the dwindling number of family members available to provide home care has further increased the use of commercial and county nursing homes for both private pay patients and recipients of public assistance.

Likewise, there is frequent evidence of the need for general hospitals to concern themselves more with measures to prevent the development of conditions which may require nursing home care after a hospital stay.

Mr. Hackley is coordinator of the rehabilitation education service of the Illinois Public Aid Commission, Peoria. The project is supported by grants from the Office of Vocational Rehabilitation, Department of Health, Education, and Welfare, the Forest Park Foundation of Peoria, and the Illinois Public Aid Commission.

The vocational rehabilitation of residents of nursing homes presents several significant problems. For instance, in the average Illinois community there is often little knowledge or appreciation of the philosophy and techniques of rehabilitation and the vocational potentials that may emerge from physical rehabilitation. Similarly, there is often little knowledge of the interests or services of the Federal Office of Vocational Rehabilitation and its counterparts in many of the States.

The Office of Vocational Rehabilitation, the Forest Park Foundation of Peoria, through the Peoria Institute of Physical Medicine and Rehabilitation, and the Illinois Public Aid Commission joined forces to conduct a 3-year research demonstration project, the rehabilitation education service. Begun in February 1957, the project, the first of its kind in the United States, proposed to look for the answers to these questions.

- What are the rehabilitation needs among patients of a selected group of public and private nursing homes?

- Can the existing staffs of these homes, in cooperation with local physicians and services in the local community, meet these needs if they receive adequate training in the philosophy and techniques of rehabilitation?

- What kind of training can be developed to provide staffs with a knowledge of rehabilitation techniques and to increase their appreciation of the philosophy of physical and vocational rehabilitation?

- What kinds of teaching materials can be developed that other agencies and schools can

the responsibility for continuing and expanding programs of improved patient care. Without their help most training programs probably will fail to achieve their objectives.

Various professional schools should also be encouraged to participate in training programs for nursing home staffs. The assistance these schools can give is invaluable.

A portent of the schools' interest in this field was the workshop on chronic disease and nursing service conducted by the division of nursing education, Teachers College, Columbia University, in New York City, June 8-19, 1959. Participants were 15 graduate nurses selected because of their knowledge and nursing experiences in chronic disease and aging, educators and administrators from the faculties of several schools of nursing, and resource consultants.

The nurses appraised and organized their knowledge and experience, and the faculty members developed a plan for the integration of this knowledge into the curriculum of schools of nursing. A report on the workshop will be published this year.

However, the fundamental dilemma is how to organize a training program adapted to the needs and circumstances of an individual community. In my opinion, the first step might be the formation of a statewide advisory committee. It should not be too large but should have representatives from any or all of these interested State groups: hospital and nursing home associations; health, welfare, licensure, and vocational education agencies; medical, dental, nursing, and other professional associations; and the American Red Cross and other voluntary agencies.

This statewide committee can advise on such matters as what program is desirable, how it can be implemented, policies and procedures to be followed, financing and coordination of the training effort, and formation of local advisory committees.

The second step might be to set up local ad-

visory committees. Their membership should also be limited but representative of all the vitally interested official and voluntary agencies as well as the press and interested lay groups.

We believe it is essential to assign a qualified, full-time person to act as coordinator for the statewide training program. His responsibility is to implement the committee's recommendations and to coordinate all aspects of the program. Similarly, each local committee should designate an individual who can work in the community and also coordinate local activities with the State program.

The success or failure of a training program often rests with the local advisory committee that, with its coordinator, actually carries out the training. Therefore, it is important that the committee considers these aspects of the local training program.

- The need for training and whether it should be formal, informal, or on-the-job instruction.

- The number, size, and location of the homes and the number and type of personnel they employ.

- The interest and concern of the homes' administrators, health, welfare, and licensure personnel, and medical and nursing professions.

- Securing a sufficient number of teachers and consultants.

- Methods of financing and various other factors that are essential to such a project.

It is hoped that some of these suggestions will assist the promotion of training programs to improve the care of persons in nursing homes. Ultimately, improved care for them depends on the interest and concern each of us has for their well-being. We can establish and maintain good training programs for nursing aides and we can effectively engage in many other activities in behalf of residents of nursing homes and homes for the aged only if we focus on the needs of the individual patient.

tend. These lectures cover the following subjects:

- Philosophy of rehabilitation and rehabilitation nursing.
- Occupational therapy.
- Patient approach and motivation.
- Body alignment, bed positioning, deformities, and contractures.
- Body motion and exercise.
- Activities of daily living and training, including devices.
- Bladder and bowel control and training.
- Ambulation activities.
- Passive range of motion, group exercises.
- Personal hygiene, speech and hearing rehabilitation.
- Recreational, functional, and group activities.
- Prevocational services.
- Physical environment.
- Social services.
- Community and volunteer programing and services.
- General nutrition.
- Role of the family in a patient's rehabilitation.
- Resource material for the nursing home staff.

Team members spend most of each day in demonstration, return demonstration, and bedside work with individual members of the nursing home staff. We have found that nursing home personnel tend to be uncomfortable when dealing only with concepts, and that it is most effective to teach specific, concrete techniques and to let philosophical concepts of rehabilitation emerge as lecture material is put into practice.

The length of the team's stay depends largely upon the size of the nursing home and the number of persons to be trained. In practice, the training period has averaged approximately 6 weeks; the range has been from 4 to 8 weeks.

One nursing home staff member, assigned by the administrator, is trained by the occupational therapy consultant to be the activities director of the home. The activities director has primary responsibility for planning and conducting recreational and diversional programs, recruiting, training, and supervising volunteers, and for promoting community-related activities. The activities he heads embrace all aspects of occupational therapy except prevocational testing and functional work.

The project team presents a list of equipment for rehabilitation nursing and occupational therapy which the nursing home is supposed to provide. Patterns are included for items on the list which the home can make. The rehabilitation nursing equipment is limited to such aids as footboards, sandbags, and pulleys. Their total cost is approximately \$7. The tools, equipment, and supplies requested for starting an occupational therapy program that includes 20 basic crafts and innumerable recreational program materials cost approximately \$32.

Adaptations for toilets and tubs, parallel bars, and similar equipment are not on the list of requested items. We prefer to demonstrate various substitutions or less expensive improvisations which will help the home realize the value or need for such equipment. If the home believes that various pieces of equipment will be useful, we then provide patterns so they can be constructed as inexpensively as possible.

When the rehabilitation program has been operating for 1 year, the project team which conducted the initial training and made the monthly followup visits returns to the home for a 2-day exhaustive evaluation. Several weeks in advance, the administrator and staff are notified of the evaluation and of certain considerations to be discussed at staff meetings and during the evaluation.

Afterwards, the team discusses with the administrator the program's strengths and weaknesses. The team then remains in the home several days to give short-term intensive training to correct the weaknesses found during the evaluation.

Experience seems to confirm that providing training within the facility is most practical. The administrator and staff receive the same lectures and participate in the same discussions, thus improving communication between them. Clinical experience within their own institutions permits the staff to adapt training to the patients they routinely serve and to recognize and deal with problems and approaches in patient motivation.

Inasmuch as rehabilitation services call for a marked change in the nurse's attitude toward patient care and an appreciation of the importance of activities in the total treatment of the

use to increase the competence of nursing home staffs to share in vocational and physical rehabilitation?

Framework of the Project

The Peoria Institute of Physical Medicine and Rehabilitation provides medical supervision for the project. A grant from the Forest Park Foundation enables the director of research and education of the institute to devote 1 day a week to such activities as visits to cooperating nursing homes, meetings with their staffs, direct medical supervision of the project staff, and, upon request, giving more detailed interpretation to the patients' attending physicians.

The project staff consists of four rehabilitation nursing consultants, two occupational therapy consultants, and a supervisor. Two nursing consultants and an occupational therapy consultant, with one of the nurses as supervisor, form a training team.

Because the rehabilitation education service is a staff training program rather than a direct service to patients, the project's particular combination of professional staff does not include a physical therapist or a vocational counselor. The teaching of physical therapy is confined to aspects which the various professions involved have agreed can be legitimately carried out by nurses properly trained and supervised in rehabilitation. Therefore, the teaching embraces such care as passive range of motion exercises and gait training which the nursing home personnel can carry out within the framework of a nursing home program. However, if intensive physical or other therapy for some patients seems indicated, homes are encouraged to employ a physical therapist part time, or, at the request of the attending physician, to obtain the services of a physical therapist who can treat a patient.

Experience seems to indicate the need for a medical social worker on the project staff in the near future. Most nursing homes are not prepared to provide professional casework services for patients or families, but certain techniques for interviewing and other intake procedures are not only useful but needed in many homes. Certainly, basic casework concepts are invaluable to nursing home personnel,

particularly in patient approach and motivation. However, it is our opinion that a patient who needs the integrated services of all the disciplines associated with rehabilitation should be in a rehabilitation center.

During the first 4 months of the project the staff, under the supervision of the institute, designed the materials and procedures to be used in the nursing homes. Fieldwork began June 15, 1957, and we are now conducting the program in the 36th and 37th cooperating homes. The homes have ranged in size from 15 to 243 beds.

The applicant nursing home must meet certain criteria. The administrator or governing body of the home must voluntarily request participation. The home must be currently licensed by the Illinois Department of Public Health. A full-time registered nurse or licensed practical nurse must supervise nursing. The home must accept public assistance patients and currently have such patients.

Approximately 20 percent of the eligible nursing homes in Illinois have applied for the service. The applications on hand are somewhat fewer than the initial number, but the present backlog necessitates a waiting period of approximately 6 months.

After receiving an application from a nursing home, the coordinator of the project visits the home to meet the administrator and staff and to explain in detail the content and procedures of the rehabilitation education service. The project staff then discusses the application and informally consults the regulatory agency to ascertain the home's administrative attitudes, atmosphere, and history of patient care. If acceptance of the application seems indicated, the training team visits the home to work out the details of introducing the service.

Conducting Training

In conducting the training, a project team spends 4 days a week for 4 to 7 weeks at the cooperating home. Mondays of each week are reserved for monthly followup visits to homes that have already received the service. During the training period, daily 1-hour lectures are held for all persons on the staff who are in contact with patients. If necessary, the lecture is repeated so that the entire staff can at-

that they appreciate more the role of occupational therapy in nursing care. They believed that their patients have gradually accepted the rehabilitation philosophy and have willingly accepted responsibility for increased self-care.

The nursing home personnel appraised as the program's two greatest benefits their own change in attitude toward goals for their patients and their acceptance and understanding of the basic principles of rehabilitation. They concluded that programs such as the one established by the project were feasible for a nursing home of any size, but felt that the program's intensity and scope depend upon individual attitudes of the administrator and the nursing personnel.

The administrators of 18 cooperating homes assisted in an exhaustive evaluation of the training content and methods of operation of the rehabilitation education service. For this evaluation, the project staff interviewed orally the administrator, the nursing staff, and selected patients of the 18 homes. They were asked 35 questions covering all aspects of the rehabilitation program.

Some generalizations regarding such training programs were drawn from their answers.

- It is essential that the program be requested voluntarily and desired by the home if the training is to be effective and the program continued.

- The staff must have stable employment, be highly motivated, and be experienced in nursing service if maximum benefit is to be derived.

- A training program can provide the staff with nothing more than specific tools and techniques to be used in medically prescribed rehabilitative care of patients.

- Most problems for staff members were associated with nursing aspects of the program rather than occupational therapy or activities, possibly because in nursing, outmoded techniques and procedures which have become habitual must be unlearned, but occupational therapy is new to them and is not resisted because of tradition or long-established practice.

- Rehabilitation services can be built best upon the soundest basic nursing possible. An institution with good administrative procedures and personnel policies and acceptable in-

take policies and procedures is the most promising setting for such a program.

- The cooperating homes considered the cost of such training and the maintenance of the program reasonable. The greatest expense was the staff time devoted to training sessions during the initial phase of the program. Generally, the cost for equipment and basic preliminary supplies has averaged about \$40 per home. The homes have found various ways of absorbing the cost of materials for continuing occupational therapy. Most frequently, they use income from salable items to purchase additional supplies, or philanthropic groups and service clubs in the community supplement the crafts budget with donations.

Problems

Those concerned with the services of nursing facilities and the rehabilitative care of older patients should remember that a program such as the rehabilitation education service can never solve all problems. There is no question in the minds of the project staff but that the scope, quality, and philosophy of service have been markedly changed in each nursing facility in which the program has been conducted. But staff education cannot be expected to meet such problems as placement of patients in inappropriate facilities, conflict between high standards of service and low rates of payment, lack of counsel and casework services for patients and their families, and lack of appropriate facilities for discharged patients.

However, such projects as this are in a relatively ideal position to observe the frequency of such problems and indicate possible useful tools in exploring and developing solutions. Also, the project serves as an excellent unit for the finding of patients in need of certain facilities and services. The project staff constantly encourages nursing homes to see themselves as casefinding units with regard to patients, their families, and overall community needs.

Although stability of staff in the cooperating homes is extremely difficult to measure adequately, our observations indicate a trend toward reduced turnover in some facilities after such a training program has started. In others, continued turnover tangibly affects the efficiency of the rehabilitation services that

patient, during full-time association with the staff the teaching team can demonstrate how the philosophy of rehabilitation must permeate every nursing activity extended to the patient.

Also, this approach creates an excellent opportunity to interpret further to physicians the nature and scope of the nursing home's services. Most patients in the cooperating homes have their own physicians, and we require the physician's prescription before a patient may participate in any phase of a rehabilitation program. Finally, in this setting the teaching staff can identify problems of patient care in the specific home and assist the administrator in working out a plan of care suitable for the individual patient in terms of staff capabilities.

Results

We are frequently asked our goals for a nursing home patient. Since this is not a treatment program but a training program for nursing home staff, goals are for the staff rather than the patient. No one can delineate absolute goals for an individual patient; his potential and response to treatment, frequently unpredictable, govern his rehabilitation.

In general, the patients' responses to treatment have fallen into three general categories. Approximately 5 percent of the initial patients indicated adequate potential to warrant a referral to the Illinois Division of Vocational Rehabilitation. However, this percentage is diminishing. Response to rehabilitation measures has resulted in the discharge or the pending discharge from the nursing home of approximately 25 percent of the patients. Rehabilitation measures have brought increased self-care and independence within the nursing home to about 60 percent of the patients. The attending physicians of the remaining 10 percent did not prescribe participation in rehabilitation activities. Most of these patients had severe cardiac disorders or terminal illnesses.

Nursing homes which have had this training are being used for maintenance rehabilitation or the completion of rehabilitation of some patients, permitting their early transfer from the Institute of Physical Medicine and Rehabilitation. The improvement of some patients would allow their return to the community, but they are unable to because they lack financial

resources, the family is unable to fulfill its role in the situation, or community resources are inadequate.

In assessing the training, we find that every moment spent in a home is a demonstration of our conviction of the need and efficacy of rehabilitation. Indirectly, we see a new motivation for the staff stemming from the improved morale and health of the patients and a new reason for both patients and staff to do more than was formerly considered not only enough, but actually was thought to be good care.

Similarly, there emerges that almost inevitable change in attitude that goes hand in hand with the consciousness of improved technical skills, especially if the result is happier, healthier patients. This attitude is evident in comments from cooperating homes. None has expressed disappointment with the conduct of the training or the continuing program. However, on innumerable occasions staff members have said that it is a slow process for them to incorporate the philosophy of rehabilitation in all aspects of administration, planning, and care.

Frequently, staff members are discouraged because only a small number of the present patients can benefit dramatically from rehabilitation services. We endeavor to point out that if work is begun with a patient 5 to 10 years after the initial insult, there is rarely an opportunity to see as graphic a demonstration of the benefits of rehabilitation as with newly admitted patients. On monthly followup visits the teams have found that nursing home personnel are most eager to demonstrate their work with newly admitted patients and the gains they have seen these patients make.

Evaluations

Administrators and staff of the first 10 homes in which the annual evaluations, described previously, were held indicated what they had gained from the project. Nursing staff members said they now know more about caring for patients, especially the patient with hemiplegia, a fracture, or arthritis. They felt that their training has also improved the quality of the basic nursing care they give to patients.

Administrators and staff members indicated that they are much more aware of patients' needs for social activities and motivation, and

Training Nursing Home Administrators

HERBERT R. DOMKE, M.D., Dr.P.H., and JOHN C. MURPHY, M.D.

THE TRAINING of nursing home administrators and staff is recognized as an essential component of programs for improving the care of patients in such institutions. Although inspection and regulation have proved of great value, a considerable area of nursing home operation remains outside the scope of legislation. Various nursing home associations and Federal, State, and local agencies have developed training courses and materials (1), and the National Conference on Nursing Homes has recommended development of training programs (2). In Missouri, the St. Louis County Health Department has conducted a training program for administrators of these homes.

A description of the training project has been published (3). We present here a brief review of some pertinent general aspects with a summary of the program's development.

In reviewing the St. Louis program, we do not attempt to evaluate degree of success in achieving the ultimate product, that is, the improvement of services to residents. It would be difficult to separate the effects of a formal training program from those of other activities, such as official inspection, which also influence patient care in nursing homes. Also, there were major legislative and regulatory changes during the course of the program.

There are 57 nursing homes in St. Louis County providing 2,500 beds. One of the

homes, operated by a church, is not included in the analysis. In comparison with nursing homes throughout the Nation, those in St. Louis County are reasonably typical. Data on the age distribution of residents, and their medical and nursing service needs, as well as financial support, show that the county is in the median range for the United States.

When the department developed an intensified inspection program in 1954, it quickly became clear that the nursing home administrator's education or experience usually did not include medical or other professional training. It was also clear that other information on operation of a physical plant and administrative techniques, such as cost accounting, might be discussed profitably in an educational program. Certainly, the administrator needs many skills which he has little opportunity to develop except by unguided experience. It seemed desirable therefore to develop a series of educational meetings with the primary purpose of instructing nursing home administrators.

Educational Meetings

To help plan the educational meetings, a policy committee was formed with representation from two independent nursing home associations and from homes not participating in either association. Also on the committee were medical, nursing, and sanitation personnel of the health department. Topics for the programs were selected by the committee, which recommended that 2-hour sessions be held in the afternoon once a month. Seventeen meetings were held, the first in June 1956, and the last in January 1958.

Dr. Domke, who is now health director of the Allegheny County Department of Health, Pittsburgh, Pa., served as commissioner of health of St. Louis County, Mo., when this paper was written. Dr. Murphy is assistant commissioner of the St. Louis County Health Department.

have been started. Eventually, a plan may be devised to give new staff members the same intensive training the rest of the personnel have already received.

The loss of a home's activities director would critically impair this phase of the rehabilitation work. During the remaining demonstrations, we plan to try to prevent or solve this possible interruption in a home's program.

In spite of the growing prominence of nursing homes in the total medical care spectrum of the community, far too few administrators or medical personnel appreciate adequately the appropriate role of nursing home care in rehabilitation. In the nursing home lectures, community interpretations, associations with related services, and discussions with patients' families, we stress the totality of services needed for realistic rehabilitation planning—social, economic, vocational, psychological, and physical. No other area of concern for people involves such a multiplicity of patient needs.

Because of their profit-making nature, proprietary nursing homes frequently are reluctant to consult with community agencies or to request direct services from them for patients. The rehabilitation education service staff assists these homes in contacting pertinent agencies such as the Illinois State Division of Vocational Rehabilitation and public and private agencies and establishing close working relationships.

This reluctance may perhaps be explained by the similar feeling of some agencies and programs to serve nursing homes which are operated for a profit. In some areas, the nursing home, as a medical care facility of the community, still does not enjoy broad understanding of its role in the care of the chronically ill, nor is it afforded its rightful position of respect by professional and lay people.

Conclusions

Dr. Theodore G. Klumpp, in his paper entitled "Promotion of Health Maintenance and

Restorative Services," stated, "The achievement of absolute and unquestioned scientific proof of the many basic facts concerning the aging process will take time, perhaps years and generations in the life of man. Are we to sit by and do nothing until the pieces of information are collated and nailed down as solid facts or are we justified in taking the best we have at the time as working hypotheses and apply them to useful ends? I think we are."

We feel the rehabilitation education service has proved to be needed and effective in the broad area of care for the chronically ill, disabled, and aged; but beyond this we believe that it demonstrates three important facts.

1. Public assistance agencies can be concerned with more than buying the best service at the lowest price. They can legitimately be concerned with improving existing services, offering new ones, and stimulating the development of those services which their clients need.

2. Whether this kind of service on the State or local level is offered by public health, public assistance, or vocational rehabilitation agencies, no one agency really offers the service. Only the combined, coordinated efforts of all make any such service in rehabilitation effective and worthwhile.

3. In a general way, such projects as this can do much to bring better understanding to the possible conflict between improved standards of care and reasonably low rates of care, particularly for the medically indigent.

With only 2½ years of experience in the project we are far from the answers to many questions. We may not even know some of the questions. But there is ample accumulating evidence that such a program can be effective and helpful to people.

We know that it calls for each agency concerned to inventory frankly its present services and its philosophy of program goals. Active participation in such programs enhances not only our skills but also our appreciation of how each agency is professionally and morally involved in comprehensive rehabilitation.

Table 2. Selected characteristics of nursing homes as related to representation at the educational meetings

ance of formal training activities. In addition, special emphasis was given to investigation of the relationship between the type of home and acceptance of lecture-and-discussion-type training. Interviews were conducted by experienced interviewers, and data obtained were verified when possible by official health department records.

Table 2 provides information regarding selected characteristics of nursing homes together with information regarding attendance at the series of meetings and demonstrates the marked relationship of attendance to ownership and to size of home. Attendance data were also appraised by age and sex of the administrator but no major relationships were seen.

Administrators who attended least often were those from the largest institutions and from the institutions of charitable or church sponsorship. All but two administrators of the nonproprietary institutions attended at least one meeting

but thereafter came to only 2.9 meetings, whereas administrators of proprietary institutions, on the average, attended 7.5 meetings.

Table 3 provides a review of the education and previous work experience of administrators using the same nursing home categories as table 2. As expected, administrators of the larger and the nonproprietary institutions tended to have more educational background and were more likely to have had training in one of the professions related to medicine. These data show that the St. Louis County program, on the average, was best received by the administrator with the least education and whose previous work experience was not likely to have been in one of the professions related to medicine.

The educational data are pertinent also in considering programs to raise nursing home standards. Only approximately half of the nursing home operators have completed high school. Professional personnel in public health

The educational material at the meetings was presented by members of the health department or other qualified persons, such as the county fire marshal and the director of welfare. The lecture presentation was followed by a period of discussion from the floor.

Attendance at the meetings was voluntary but was encouraged by the health department, and by the nursing home members of the policy committee through telephone calls and announcements at nursing home association meetings. The audience was somewhat reserved initially, but as the meetings progressed there was more open discussion. In the beginning there was very little interaction between the administrators, but, after a few meetings, a friendly relaxed attitude developed. Frequently, informal discussions continued after the 2-hour program was completed.

Table 1 presents a summary review of the topics discussed at the meetings and the number of administrators attending. Of the total number of 73 administrators representing 56 homes, all but 12 attended at least one session. Two of the three sessions with more than 50 percent of administrators attending followed immediately after the disastrous nursing home fire in Warrenton, Mo., in February 1957.

Some tendency for attendance to drop can be seen, and, for this and other reasons, it seemed desirable to undertake a critical review of the program. All administrators, without reference to their attendance at the sessions, were in-

Definitions

The following definitions of the categories of domiciliary, practical nurse, and professional nurse homes have been established by Missouri State legislation. These categories correspond generally with those of residential, personal care, and nursing care as defined for use in the 1958 National Conference on Nursing Homes and Homes for the Aged. Domiciliary homes are essentially for care of residents with little or no infirmity. The practical nurse category may accept residents requiring considerable medical and nursing supervision. The professional nurse category may accept residents requiring considerable medical and nursing supervision.

The "administrator" in this discussion is a person with principal administrative responsibility in the institution, usually as owner or co-owner but in some instances as a full-time, salaried executive. For nonproprietary institutions, which tend to have a more complex structure of administration, the definition of administrator is less clearcut.

interviewed with a questionnaire approved by the training committee to obtain their opinions regarding the training program.

A major purpose of the questionnaire was to review the educational background and experience of the administrators to determine if any relation existed between education and accept-

depend most on personality characteristics of the individual administrator, and that if educational background influenced attendance at all, the highest attendance would be found in the group with the most education. It was further expected that programs could be developed to promote a free interchange of experience and opinion of the type seen in professional round-table discussions so that all administrators would share their knowledge and skills. In retrospect, however, it is obvious that it would be an unusual program which would be profitable for the administrator of a 10-bed domiciliary home and would be appropriate as well for the administrator of a 150-bed facility similar in most respects to a hospital. The dilemma also lies in preparing a course appropriate for persons with less than high school education and for those with formal professional training beyond college.

Furthermore, consideration must be given not only to education and professional training of the trainee but also to the selection of the most appropriate setting, class size, and educational technique. The type of program reported here is desirable in providing factual information to large groups regarding such matters as interpretation of fire regulations and basic nutrition topics for which a straightforward factual account of the usual lecture form are possible. In this context it should also be recognized that the members of the official inspection team also do or should conduct an educational program. The type of training activity reported by Hackley is an example of still another educational technique. It is one which may be particularly well suited to development of rehabilitation services. (See pp. 989-994.)

From many points of view the series of 17 meetings may be considered a success. Certainly, response for a series of voluntary meetings of 40 percent of the total potential audience is exceptionally high. A fortunate aspect of the program was its location within a single county. However, the report of the Saginaw County program indicates that administrators are willing to come from considerable distances and at considerable inconvenience for educational activities developed to improve nursing home facilities and services.

From another point of view the program was

successful in that attendance was highest among those with least education and least professional experience. It would appear then that the group in greatest need was most affected. This nursing home training program is in contrast to other public education activities in which it is more usual for response to be best among the better educated in the community.

The sessions also contributed directly to a better recognition by administrators of problems common to all nursing homes and thus contributed to an increased awareness of their professional responsibilities. This, we believe, is especially important for those in proprietary nursing homes, some of whom still have a tendency to conceive of the home primarily as a commercial venture. Whatever the commercial aspects of nursing home operation, recognition by the administrators that nursing homes provide residents and the community an essential service meriting the highest professional standards may well be a prerequisite for development of the most desirable standards of patient care.

Summary

The health department of St. Louis County, Mo., conducted a training program for personnel of nursing homes as a means of improving patient care in these institutions. Fifty-six nursing homes participated in a series of 17 educational meetings, which were planned by a policy committee made up of nursing home representatives, and held once a month during the period, June 1956 through January 1958. The response in attendance was 40 percent of the total potential audience.

Questionnaires submitted to participants revealed that only about half of the administrators had completed high school. Their level of education, however, was above that of the general population in the State and the county. The program was best received by those with the least education who were not likely to have had experience in professions related to medicine.

Analysis of the project indicated that to achieve the best participation and support the program planners should take into account the education and experience of the trainees as well as their needs. The types of institution repre-

responsible for the development of training programs may well consider that a high school education is hardly adequate educational background for operation of nursing homes. It must be recognized, however, that as a group, nursing home administrators are much better educated than the general population. In 1950 the median number of school years completed by persons 25 years and older in Missouri was 8.0. For St. Louis County for the same age group, the median school years completed was 10.3, and it is noteworthy that St. Louis County was among the 5 highest of the 114 counties in the State. The educational background data reported here are consistent with that reported by Lewis (1) who gives 10.7 as the median number of school years completed for the nursing home personnel attending the Saginaw County program.

Certainly these data regarding educational background clearly confirm the need for development of training programs to improve the knowledge and skills of these groups of administrators. It is further worthy of emphasis that a perfect attendance record at the St. Louis County program would have provided 34 hours of education in 18 months. But even a perfect record could only be expected to provide a very small part of the educational training which would be appropriate.

Table 4 reviews the administrators' evaluation of the program. Information regarding the program was obtained from all administrators without regard to their attendance record. As expected, administrators attending few sessions believed there was less benefit than those who attended many.

In so reporting, it may well be that the administrator is reporting accurately. The data presented indicate clearly that the largest institutions operated by the best trained personnel participated least, and this may well be the result of the lack of appropriateness of the training sessions for this group of administrators. It is probable that the committee planning the program was more representative of the typical proprietary institution and their recommendations may have led to a program best suited to this group of nursing homes.

Evidence that those who attended least often were not antagonistic to training activities is shown by the fact that more than two-thirds believed such courses were desirable and were willing to allow employees time off with pay to attend them. The large majority were in favor of developing training activities for specific personnel such as practical nurses and cooks. There is then little doubt that administrators are favorably disposed to training.

Information was also sought as to the administrators' opinion on sponsorship of training. All but 8 of the 56 homes recommended health department sponsorship or health department co-sponsorship with the State health department or nursing home association.

Discussion

The major interest of the material presented is, we believe, in the demonstration of the need for the differentiation of program to meet the differing backgrounds and needs of trainees. When the program was first planned it was expected that the acceptance of training would

Table 4. Administrators' evaluation and recommendations regarding training

depend most on personality characteristics of the individual administrator, and that if educational background influenced attendance at all, the highest attendance would be found in the group with the most education. It was further expected that programs could be developed to promote a free interchange of experience and opinion of the type seen in professional round-table discussions so that all administrators would share their knowledge and skills. In retrospect, however, it is obvious that it would be an unusual program which would be profitable for the administrator of a 10-bed domiciliary home and would be appropriate as well for the administrator of a 150-bed facility similar in most respects to a hospital. The dilemma also lies in preparing a course appropriate for persons with less than high school education and for those with formal professional training beyond college.

Furthermore, consideration must be given not only to education and professional training of the trainees but also to the selection of the most appropriate setting, class size, and educational technique. The type of program reported here is desirable in providing factual information to large groups regarding such matters as interpretation of fire regulations and basic nutrition topics for which a straightforward factual account of the usual lecture form are possible. In this context it should also be recognized that the members of the official inspection team also do or should conduct an educational program. The type of training activity reported by Hackley is an example of still another educational technique. It is one which may be particularly well suited to development of rehabilitation services. (See pp. 989-994.)

From many points of view the series of 17 meetings may be considered a success. Certainly, response for a series of voluntary meetings of 40 percent of the total potential audience is exceptionally high. A fortunate aspect of the program was its location within a single county. However, the report of the Saginaw County program indicates that administrators are willing to come from considerable distances and at considerable inconvenience for educational activities developed to improve nursing home facilities and services.

From another point of view the program was

successful in that attendance was highest among those with least education and least professional experience. It would appear then that the group in greatest need was most affected. This nursing home training program is in contrast to other public education activities in which it is more usual for response to be best among the better educated in the community.

The sessions also contributed directly to a better recognition by administrators of problems common to all nursing homes and thus contributed to an increased awareness of their professional responsibilities. This, we believe, is especially important for those in proprietary nursing homes, some of whom still have a tendency to conceive of the home primarily as a commercial venture. Whatever the commercial aspects of nursing home operation, recognition by the administrators that nursing homes provide residents and the community an essential service meriting the highest professional standards may well be a prerequisite for development of the most desirable standards of patient care.

Summary

The health department of St. Louis County, Mo., conducted a training program for personnel of nursing homes as a means of improving patient care in these institutions. Fifty-six nursing homes participated in a series of 17 educational meetings, which were planned by a policy committee made up of nursing home representatives, and held once a month during the period, June 1956 through January 1958. The response in attendance was 40 percent of the total potential audience.

Questionnaires submitted to participants revealed that only about half of the administrators had completed high school. Their level of education, however, was above that of the general population in the State and the county. The program was best received by those with the least education who were not likely to have had experience in professions related to medicine.

Analysis of the project indicated that to achieve the best participation and support the program planners should take into account the education and experience of the trainees as well as their needs. The types of institution repre-

sented and the kind of patients they serve should also be considered in planning the program.

Reports on Radioactivity Levels

During the first half of 1959, the levels of strontium-90 in the Nation's major water courses, sampled weekly at 51 stations, were substantially below the levels set by the National Committee on Radiation Protection and Measurements as permissible for lifetime exposure of the general population.

The data are part of the information gathered on stream pollution by the national water quality network operated by the Public Health Service. This network includes 17 major rivers. Eventually, the study may provide precise measurements of the major forms of water pollution, including plankton, and the general chemical, physical, and bacteriological characteristics of the main rivers and streams.

The present network, operated in cooperation with State and local governments, universities, and industry, is expected to expand to 75 stations in the coming year and eventually to 250.

Reports on the levels of radioactivity in milk collected during July 1959 from 11 sampling stations across the country show that both the monthly levels and longer-term averages

for all radionuclides analyzed in samples from all stations remained below the levels which the national committee considers permissible for lifetime exposure of the general population.

The levels of radioactivity continued to fluctuate. The strontium-90 count decreased in July at all but 2 of the 11 stations. The Fargo, N.D.-Moorehead, Minn., area station showed a strontium-90 content of 22.1 micro-microcuries per liter, as compared with 20.6 micromicrocuries per liter in June. In the St. Louis area the strontium count was 17.6 micro-microcuries as compared with 11.2 micro-microcuries per liter in June and 34.6 micro-microcuries in May.

Milk was selected for study for specific nuclides in food because it is the most practical sample and is produced throughout the year in all sections of the country.

Both the network for measuring water quality and that for milk sampling are part of the Service's broad program for the measurement of radioactivity in air, water, and food.

STATUS

of

Tuberculosis

CONFERENCE REPORT

The present status of tuberculosis, responsible for 100 million days of illness annually in the United States, was discussed at the 1959 meetings of the National Tuberculosis Association, the American Trudeau Society, and the National Conference of Tuberculosis Workers. Approximately 3,000 physicians, scientists, public health officials, nurses, and executives and volunteers of State and local tuberculosis associations attended the May 24-29 meetings in Chicago.

Airborne Transmission

Airborne droplet nuclei were the source of infection for 71 guinea pigs breathing air exhausted from a tuberculosis ward, and 21 of these infections were traced to specific patients, reported researchers in a cooperative study by the Johns Hopkins University School of Hygiene and Public Health, the Veterans Administration, and the Maryland Tuberculosis Association.

At the VA Hospital in Baltimore, Md., a colony of approximately 160 guinea pigs breathed air exhausted from a 6-bed ward over the 24-month study period. When bacilli from 22 infected animals, cultured for drug susceptibilities, were compared with cultures of bacilli from the patients' sputums, it was apparent that two patients had produced 19 of the 22 infections. The one drug-susceptible organism probably came from a patient receiving initial treatment.

The researchers suggested that highly positive sputum and absence of effective therapy are important in determining a patient's infectivity as well as a natural mechanism for atomizing the infectious material and the continued viability and infectivity of the organism after becoming airborne. They felt that the study not only strengthened the case for airborne transmission but indicated an experimental tool for the study of the infectivity of human tuberculosis.

The investigators were Dr. R. L. Riley, C. C.

Mills, Dr. W. Nyka, N. Weinstock, Dr. P. B. Storey, Dr. L. U. Sultan, Dr. M. C. Riley, and W. F. Wells, of the Johns Hopkins University School of Hygiene and Public Health and the Veterans Administration Hospital, Baltimore.

Disinfecting the upper air of rooms with ultraviolet light appeared to block transmission of the influenza virus, according to Dr. Ross L. McLean, now at Emory University School of Medicine, Atlanta, Ga.

At the Veterans Administration Hospital in Livermore, Calif., one unit with complete facilities for the cure of patients was irradiated. Serologic samples were obtained from all hospital patients and personnel in July 1957, November 1957, and March 1958. Practically none of the patients or personnel had been vaccinated against influenza. Staff members were exposed to the respiratory infections prevalent in the community.

Between July 28, 1957, and March 15, 1958, only 4 (2 percent) of 209 patients in irradiated rooms were infected; 75 (19 percent) of 396 patients in nonirradiated rooms were infected; and 92 (18 percent) of 511 hospital personnel were infected.

The differences in the prevalence of infection, as determined serologically, strongly suggest that an important mechanism of transmission of epidemic influenza was significantly blocked, McLean stated.

Since the ultraviolet radiation was designed to disinfect chiefly the truly airborne particles, these findings suggest that an airborne mechanism is the principal mode of transmission of epidemic influenza.

Race and Environment

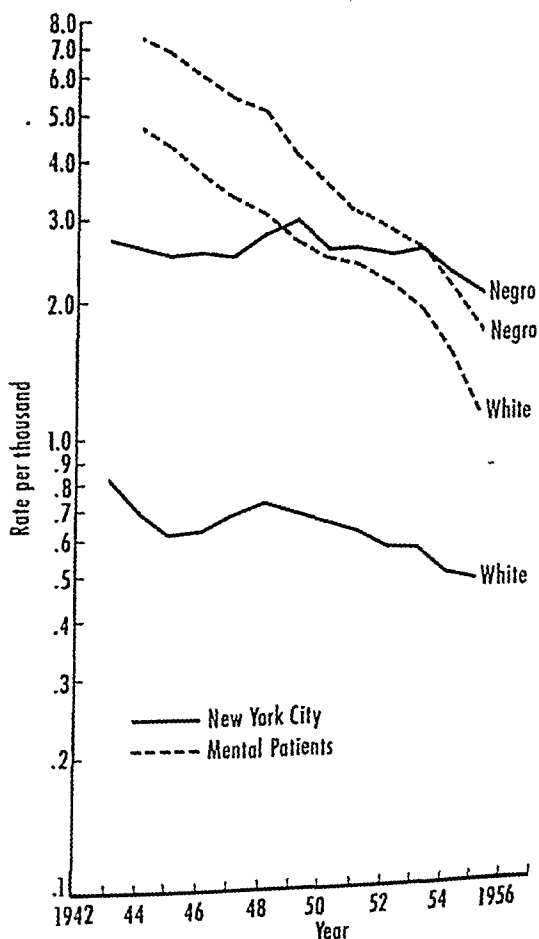

In a similar environment the response to tuberculosis of the Negro and white is similar, and racial factors probably play a minor role in producing differences in tuberculosis morbidity and mortality, concluded Dr. Julius Katz and Solomon Kunofsky, division of tuberculosis control, New York State Department of Health, Albany.

They studied white and Negro patients in hospitals of the New York State Department of Mental Hygiene, where living conditions are identical for both races. Between 1942 and

1955, the incidence of tuberculosis among the Negro patients exceeded the rate among the whites by about 50 percent. In New York City during the same period, the rate of development of tuberculosis was four times as high among Negroes as among whites (see chart). The incidence decreased at approximately the same rate for the mental patients of both groups, so that by 1955 the age-adjusted rate among Negroes was only 8 percent higher than among whites.

Even before the development of antimicrobial therapy not only was the differential between the groups reduced by similar environmental conditions but the Negroes' survival was about equal to the whites'.

Tuberculosis case-reporting rates in New York City and tuberculosis incidence rates in New York State mental hospitals by race, 1942-56

Dr. W. A. Paddon, of the Grenfell Mission Hospital, North West River, Labrador, Canada, found no special susceptibility to tuberculosis among the Labrador Eskimos and Indians.

He attributed their high tuberculosis death rate to inadequate control measures and environmental factors such as overcrowded homes, poverty, poor hygiene, and malnutrition. He described how epidemics of other diseases propagate tuberculosis and said that the effect of exposure of a community to any infectious disease will be determined by its past experience with the disease and not by the racial composition of its population.

In northern Labrador the tuberculosis death rate was cut from 300 to 30 per 100,000 from 1947 to 1956, and the percentage of X-ray films showing active or probably active lesions dropped from 20 to less than 4 percent. People originally reluctant to undergo treatment were won over once they were shown that tuberculosis could be arrested. Those spreading the disease, or likely to do so, were identified through yearly surveys done during visits by a small hospital ship with portable X-ray equipment and on followup visits by dogsled.

Hospitalization, drugs, surgery, and programs of rehabilitation and information were the major methods of control. With modern aircraft and radio communication now available, patients can be evacuated quickly to improved hospital facilities. BCG vaccination is being tried, but Paddon noted that as a result, the tuberculin test will lose its considerable diagnostic value as well as its value in studying tuberculosis in a community.

Legal Detention

How patients detained under court order are cared for in the security division of the Ohio Tuberculosis Hospital was described by Dr. Robert H. Browning, director of the hospital, and Dr. Irving Pine, Columbus Psychiatric Institute and Hospital.

Although the Columbus hospital serves a population of 6.3 million, the 17-bed division is adequate because the existence of a detention facility has prompted patients to accept care voluntarily in their home counties. Also there is a high rate of transfers from the detention

division to open wards, and some counties refuse to use the security division.

The hospital's policy is to provide recalcitrant patients with treatment and permit them activities as similar as possible to those of other patients, the authors said. The staff is urged to adopt a calm, firm approach rather than a punitive one. Differences in privileges for those in the security division include the denial of money and street clothes, censorship of mail and packages for contraband, restricted visiting hours, and being locked in their rooms at night and during rest hours. Two employees are always on duty when the patients are not locked in.

Patients who are beyond persuasion or who continue to be abusive or threatening are left alone for 24 or 48 hours in a security room with limited equipment, and often become cooperative, according to Browning and Pine. Patients are transferred to open wards when they show understanding of their situation and behave reasonably well. A committee whose members include several disciplines meets weekly to decide on transfers and other matters.

Analysis of the 50 patients cared for by the division in its 18-month existence indicates that most of them, while generally becoming more cooperative, do not behave normally. They remain dissatisfied and have varying amounts of subsurface tension.

The psychiatric resident and the consultant psychiatrist of the hospital classified the patients not only to identify various syndromes and disorders but also to study the relation of recalcitrant status to psychiatric appraisal.

The largest group of patients, 16, were alcoholics, and 7 were in an acute alcoholic episode at the time of admission. All had a personality disorder in addition to alcoholism. Many became almost model patients because the hospital filled their dependency needs.

Twelve eluded strict psychiatric classification and were described as marginal personalities. They had borderline or low intelligence quotients, seemed inadequate and immature, and had made marginal social adjustments in their jobs and families. It seemed likely they resisted hospitalization because they felt they could not adjust in the hospital.

Seven had personality disorders. Their re-

sistance to the hospital seemed to be based on a conflict produced by the family or the social milieu so that they had to refuse the need for hospitalization or risk being uprooted from a tenuous position.

The remaining patients fell into these categories: organic brain syndrome, 2; psychosis with organic brain syndrome, 2; chronic paranoid schizophrenia, 3; mentally deficient, 1; and miscellaneous unclassifiable personal problems, 7.

Casefinding

Active primary tuberculosis was found in 158 children whose disease would have been missed without the thorough checking of the family contact investigation service of the Houston Children's Tuberculosis Clinic, stated Dr. Katharine H. K. Hsu, Baylor University College of Medicine, Houston, Tex. The 158 children included 29 with positive cultures for *Mycobacterium tuberculosis*, 66 with X-ray evidence of tuberculosis, 32 whose tuberculin reactions were converted to positive within 1 to 5 months, and 31 (under 36 months of age) with infections considered active because of a positive tuberculin reaction. None showed any signs of ill health which would have prompted parents to seek medical examinations for these children.

These cases were found in 1957-58 on examination of 825 children contacts of 129 family groups. Contact investigation began when a child in the family was diagnosed as having active primary tuberculosis. The immediate family as well as close contact families were examined. Adults were screened with 70-mm. microfilms. Among 582 adults screened, 26 cases of active pulmonary tuberculosis were found. Children were tuberculin tested. All positive tuberculin reactors were given thorough clinical and bacteriological examinations. Negative reactors were given periodic tests to detect conversion of tuberculin reaction.

Intensifying contact investigation and giving proper attention to childhood tuberculosis will enhance greatly tuberculosis control, Dr. Hsu said. This can be done successfully with an organized effort of local health agencies and proper education of patients' families.

The family contact investigation service which operates in cooperation with existing public health facilities in Houston and Harris County, was established with grants from national, State, and local tuberculosis associations. Its annual operating expenses amount to \$8,650.

If tuberculin tests are substituted for X-rays of pregnant patients, significant nontuberculous disease in nonreactors may be missed, affirmed Dr. Dorothea D. Glass, Woman's Medical College of Pennsylvania, Philadelphia. To determine whether the tuberculin tests were an adequate replacement for photofluorograms, both diagnostic aids were employed with obstetrical patients at two Philadelphia hospitals.

In a 6-month period at Woman's College Hospital, no significant lesions were found among tuberculin reactors or nonreactors, although 20 percent of the 308 women participating reacted to first strength PPD and 13 percent to both first and intermediate strength doses. One patient failed to report for her X-ray, and 13 percent failed to complete tuberculin tests.

The absence of lesions in this group was attributed to the relatively high socioeconomic level of the clinic patients. Therefore, the study was extended to 630 patients of Blockley Division of Philadelphia General Hospital. They were primarily women on public assistance, among whom, it was felt, would be a higher percentage of tuberculin reactors and some clinical tuberculosis. The age and race composition of both hospital populations was similar; 90 percent were Negroes between 15 and 35 years of age.

These women were tested on admission, most often immediately postpartum. Of the 432 women whose tests were read, 23 percent reacted to first-strength PPD. Thirty-one percent were discharged before the test could be read; the average hospital stay is 2 or 3 days, despite the hospital policy of a 5-day postpartum stay. Only one patient at Woman's College Hospital did not have an X-ray taken; 19 percent of the Blockley patients had no chest X-rays during their hospital stay.

X-ray findings were significant for two asymptomatic nonreactors; one had sarcoidosis, the other a congenital heart lesion. No previously unsuspected active tuberculosis was found.

Before relinquishing the gains available through routine X-rays of pregnant women, consideration should be given to the probability that the return rate for reading tuberculin tests may be as low as 50 percent, and significant previously unsuspected nontuberculous disease may be missed if only reactors receive X-rays, maintained Dr. Glass.

Co-authors were Dr. Fruma W. Ginsburgh, Dr. Katharine R. Boucot, Marie Capitanio, and Leonora Gray, Woman's Medical College of Pennsylvania, and Bernard Broad, Temple University School of Medicine, Philadelphia.

BCG Vaccination

A 20-year study showed a statistically significant difference in the number of cases of tuberculosis among infants who received BCG vaccinations and control subjects, reported Dr. Sol R. Rosenthal, director, tuberculosis prevention research, Chicago Municipal Tuberculosis Sanitarium; medical director, Research Foundation, Cook County Hospital; and director of the Institution for Tuberculosis Research, University of Illinois, Chicago.

Among the 1,665 control subjects there were 57 cases; among the 1,716 infants vaccinated, 16 cases ($\chi^2=24.62$; $P=<0.001$). The study included 3,381 infants born at Cook County Hospital, Chicago, from 1937 to 1948. All were from nontuberculous households in areas with high tuberculosis incidence.

The followup items, continued until 1957, included birth weight, sex, race, area of birth, extent of contact with tuberculosis, examinations in the clinic, X-rays, tuberculin tests, and tuberculin conversion rates. A total of 80 items were card cataloged, tabulated, and submitted for statistical analysis.

The overall comparability of the vaccinated and the control subjects appears adequate in most respects, and statistically significant differences have been identified for consideration and assessment for medical importance, stated the statistical analyst, Dr. H. C. Batson, professor of biostatistics, public health department, University of Illinois.

Other co-authors were Dr. Erhard Loewinson, Dr. Mary L. Graham, and Margaret G. Thorne of Chicago Municipal Tuberculosis

Sanitarium, and Dorothy Liveright and Violet Johnson, Institution for Tuberculosis Research, University of Illinois, Chicago.

Reinfection

Age, sex, and lack of exposure to a fresh source were factors indicating an endogenous origin for reinfection in a study of 113 patients with chronic pulmonary tuberculosis by Bellevue Medical Center researchers. The patients, all with previous primary infections diagnosed during the pediatric age range, were seen at the chest clinic of the children's medical service of Bellevue between 1930 and 1956.

Risk of developing chronic pulmonary tuberculosis is greatest in adolescence and in children who had primary tuberculosis after 6 years of age. The rate for girls was higher than that for boys. Chronic pulmonary tuberculosis was first diagnosed within 2 years of menarche for 40 percent of the girls.

Histories of 71 patients indicated exposure to a case of tuberculosis at the time the primary infection was diagnosed; only 7 histories indicated renewed exposure when the chronic pulmonary disease was diagnosed. In the majority of cases, no anatomic relationship between the site of the primary and the chronic pulmonary tuberculosis could be established. The chronic disease was discovered through routine X-ray of two-thirds of the patients.

Following is the present status of the 113 patients:

	Male	Female
Followed to 25 years of age.....	20	34
Followed to 21-24 years of age.....	6	6
Still under 21 years of age.....	2	6
Tuberculosis deaths.....	8	24
Nontuberculosis deaths.....	1	1
Lost to followup.....	0	5
Total	37	76

The death rate from chronic pulmonary tuberculosis was 21.6 percent for the boys and 31.6 percent for the girls. Of the 32 deaths, 22 occurred in patients who were first diagnosed with minimal disease. None received specific therapy during the primary phase. Only 20 patients received antimicrobial therapy for chronic pulmonary tuberculosis, and in only

three instances was treatment given within a year after the diagnosis was established.

The findings indicate the importance of keeping children with primary tuberculosis under long-term observation to gain information about the pattern of later development of chronic pulmonary tuberculosis, stated investigators Dr. Edith M. Lincoln, adjunct professor of pediatrics; Dr. Lilian A. Gilbert, associate clinical professor of pediatrics; and Dr. Soledad M. Morales, instructor in pediatrics. All are with the New York University, Bellevue Medical Center, New York City.

No relapses after 5 years occurred among 83 percent of 669 patients with negative sputums at least 6 months prior to discharge, reported Dr. Thomas F. Sheehy, medical director, Firland Sanatorium, Seattle, Wash. Relapses occurred in 11.2 percent of the original sample, 9.6 percent in the first year. There were 42 deaths from nontuberculous causes and 3 deaths from tuberculosis in patients whose disease had relapsed.

The only criteria for selection were sputum negativity for 6 months and live discharge. Status was determined as of December 31 of each year. Relapse was defined as the occurrence of positive bacteriology on a single or repeated occasion either by smear, culture, or X-ray worsening not explainable by some other acute identifiable cause.

Sheehy found that relapse occurs more commonly in middle-aged males with far advanced, cavitary disease with a secondary diagnosis of alcoholism who leave the hospital against advice. It is least common among young females with noncavitary disease who have undergone resection. Apparently, longer periods of chemotherapy prior to discharge and prior to final determination of status exert a favorable prognostic outlook.

New Techniques

Promising new techniques, a diagnostic blood test for tuberculosis and two rapid, simple methods of detecting viable tubercle bacilli in sputum, were described by several investigators.

Dr. Robert C. Parlett and Dr. Guy P. Yonmans, Northwestern University School of Med-

icine, developed a serum gel diffusion test. An agar suspension of tubercle antigen at the bottom of the test tube with a covering layer of pure agar receives the patient's serum. Acid-fast antibodies diffuse toward the center of the tube, forming a precipitation ring when fixed by the test antigen.

In serums from 465 nontuberculous persons, 97.9 percent possessed no antibody to mycobacterial antigens by this test, and only 2.1 percent of the reactions were false positives. Gel diffusion tests were positive in 84.2 percent of serum specimens from 380 patients with far advanced active pulmonary tuberculosis, in 73.5 percent of 245 patients with moderately advanced active pulmonary tuberculosis, and in 57.8 percent of 128 patients with minimally active disease. The department of microbiology of the medical school and 20 hospitals and sanatoriums cooperated in extensive double blind field trials to determine the sensitivity, reliability, and limitations of the diagnostic test.

Reporting on the use of the test at the Suburban Cook County Tuberculosis Hospital-Sanitarium, Hinsdale, Ill., Dr. William Lester stated that serums from 188 of 193 patients with bacteriologically confirmed disease were positive. He also said that all test results were positive in specimens from 28 patients with photochromogenic infections and in 78 percent of the specimens from patients with scotochromogenic cultures.

A mouse test to detect tubercle bacilli in sputum and gastric lavage specimens failed only once in 362 clinical trials and is much faster and more sensitive than conventional procedures, according to Dr. David Gale, Elizabeth A. Lockhart, and Alexander Jack, Veterans Administration Hospital, Albuquerque, N. Mex.

In the test they devised, a portion of the concentrate from the specimens was injected intraperitoneally into four mice, together with hog gastric mucin. The animals were sacrificed at 5, 10, 15, and 20 days; gross pathological changes were noted; and impression smears of splenic tissue were studied microscopically for acidfast bacilli, with each slide taking 10 minutes.

The study group consisted of 188 tuberculous patients in various stages of the disease, 55 pa-

tients admitted to medical wards, and 119 outpatients. Specimens from 74 patients were positive by both mouse test and by culture. All these patients were positive by mouse test in 15 days, compared with 52 days required by the conventional technique; 97 percent were positive in 10 days, and 85 percent in 5 days.

The mouse test also detected acidfast organisms in specimens from 64 patients whose cultures were negative. Half of these patients had positive cultures at some time during the previous year.

A new 5-day slide culture technique tested on 100 sputum samples had a 98-percent success rate compared with a rate of 69 percent when the conventional method was used, reported a team of Massachusetts investigators. For the test the researchers developed a new mucolytic and proteolytic enzyme which liquefies sputum more efficiently and is less toxic to acidfast organisms. They eliminated centrifugation and collected the acidfast micro-organisms on glass coverslips treated with silicone, a substance to which the acidfast micro-organisms have an affinity. After a 5-day incubation period the coverslip samples are treated with a modified Hanks' differentiating acidfast stain, permitting superior microcolonial differentiation of acidfast micro-organisms even under low magnification. The developers of the test are James B. Gray, State Public Health Department Laboratory, Boston; Dr. Sanford Chodosh, Lung Station (Tufts), Boston City Hospital; and Edith Reinisch, Westfield State Sanatorium, Westfield, Mass.

Other Lung Diseases

Despite thorough safety precautions, laboratory personnel working with the causative agents of psittacosis and Q fever sometimes become infected, stated a Johns Hopkins University School of Medicine researcher, Dr. Allan H. Levy.

He reported on 12 cases of psittacosis and 27 cases of Q fever which occurred sporadically in the microbiological laboratories at Fort Detrick, Md. Eleven of the twelve patients with psittacosis had worked directly with the virus, but only two had been aware of a laboratory accident.

The illnesses were somewhat milder than naturally acquired infections. Eight patients had an abrupt onset with malaise, headache, chills, and fever; four had an insidious onset. Cough was common but often did not develop until the second week of illness. Rales were heard early in the course of illness of three patients, but did not develop until the fourth or fifth day of hospitalization in six others. X-ray findings of pulmonary infiltration were noted in the lower or middle lobes of 10 patients and the upper lobes of 2. Nine patients were treated with one of the tetracyclines, chloramphenicol, or penicillin, and all responded promptly.

Only 18 of the 27 patients with Q fever worked directly with *Coxiella burnetii*, although several others were infected while in areas adjacent to laboratories. In four, the source of infection remained obscure. None of the illnesses was severe, and only 21 of the 27 required hospitalization.

Although most patients had been vaccinated with both Q fever and psittacosis vaccines, complement-fixing antibody titers after infection were higher and persisted longer than those resulting from immunization. It was not possible to determine if the large proportion of mild illnesses was the result of prior immunization or the mode of infection or the result of effective case detection through continual surveillance of a closed population.

Co-authors were Dr. Edward W. Hook and Dr. Robert R. Wagner, Johns Hopkins University School of Medicine.

Several attitudes toward the relationship between smoking and lung cancer prevail, stated Dr. Dean F. Davies, administrator for research on lung cancer, American Cancer Society, New York City. They can be categorized on five decision levels—intuition, clinical judgment, epidemiological evidence, pathogenetic evidence, and “proof positive.” The present status of knowledge falls short of definitive proof, but the evidence is sufficiently impressive to satisfy most observers.

Although the condensates derived from tobacco smoke and atmospheric pollutants produce cancer on skins of selected strains of animals, invasive epidermoid lung cancers have not been reported following exposure to typical samples of these agents. Changes in

three instances was treatment given within a year after the diagnosis was established.

The findings indicate the importance of keeping children with primary tuberculosis under long-term observation to gain information about the pattern of later development of chronic pulmonary tuberculosis, stated investigators Dr. Edith M. Lincoln, adjunct professor of pediatrics; Dr. Lillian A. Gilbert, associate clinical professor of pediatrics; and Dr. Soledad M. Morales, instructor in pediatrics. Public Health Nursing Services to Patients

Fourth in a series of reports resulting from a study of public health nursing functions, this monograph describes the public health nursing care received by individual patients within diagnostic categories. Previous papers have dealt with the study design, with the subsequent public health nursing service provided in households as a result of the referral of the initial patient from that household, and with the extent of public health nursing services given on a family basis.

Basic data were taken from individual patient records submitted by two nurses in each of five health departments and three combination agencies over a 2-year period. Public health nursing service in each of these agencies was on a generalized basis.

The data include all the public health nursing services given to individual patients and the types of situations and problems related to the recovery or the improvement of the patient which were encountered during the provision of that service. The focus of the study was on the individual and his nursing care rather than on the nurse and her activities.

The diagnostic category of the patient is the primary classification used for the entire analysis. The term "patient-nurse contact" is used to describe all the public health nursing services given to or in behalf of the patient regardless of the place or the method, such as home or telephone.

Within this framework, areas of public health nursing services where little information has been available previously are identified and documented. One such area is what activities constitute public health nursing service; another is under what circumstances and for what reasons service is provided. Data on how and

where nursing services were given supply evidence that the usual reporting of nursing services to and in behalf of patients overlooks many effective services which nurses provide through telephone calls and letters. The numerical data on the patients who had two or more diagnoses give clues to the location of "hidden patients" for some diagnostic categories.

Types of Service Provided

That the amount and kind of nursing service received by patients are directly related to the type of disease or condition present was borne

Public Health Monograph No. 59

Public Health Nursing Service to Patients. By *Marion Ferguson*. Public Health Monograph No. 59 (PHS Pub. No. 685), 52 pages. U.S. Government Printing Office, Washington, D.C., 1959, price 40 cents.

The accompanying summary covers the principal contents of Public Health Monograph No. 59, published concurrently with this issue of Public Health Reports. The author is with Public Health Nursing Services, Division of General Health Services, Public Health Service.

For readers wishing the data in full, copies are on sale by the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C. Official agencies and others directly concerned may obtain single sample copies without charge from the Public Inquiries Branch, Office of Information, Public Health Service. Copies will be found also in the libraries of professional schools and the major universities and in selected public libraries.

the epithelium of the tracheobronchial tree, including both inflammatory and proliferative reactions, following chronic exposure to cigarette smoke and simulated atmospheric pollutants have been observed.

Epidemiological data are inadequate to quantify the roles played by cigarette smoke and atmospheric pollution in the causation of lung cancer. For future research it would be desirable to continue efforts to produce epidermoid lung cancer experimentally in animals by these agents, he said. Either on human or

other animal populations it would then be desirable to study host factors, including genetic, immunological, and endocrinological influences, as well as history of previous disease, congenital conditions, and psychological factors.

The carcinogenicity of each fraction of tobacco smoke condensate should be tested for the lung as has been done for the skin. The identification of noncarcinogenic substances from both sources and a study of their contribution to proliferative changes in bronchial epithelium also require close attention.

Personnel Announcements

Dr. Morris Schaeffer, noted virologist, resigned from the Public Health Service June 30, 1959, to become director of the bureau of laboratories in the New York City Health Department. He has been chief of the Virus and Rickettsia Section, Laboratory Branch, Communicable Disease Center, Montgomery, Ala., since 1949.

Dr. Schaeffer, who has been active particularly in the fields of poliomyelitis and influenza, will also be on the staff of the New York City Public Health Research Institute and professor of medicine at the New York University-Bellevue Medical Center. Besides developing an outstanding scientific staff, he directed training courses in virology and rickettsiology which attracted large numbers of students from around the world.

Dr. Robert Dean Wright has been appointed to the new post of assistant director for medical and health activities of the Office of Vocational Rehabilitation. A commissioned officer of the Public Health Service since 1938, Dr. Wright was detailed from the position of deputy regional medical director and general

health services director at Charlottesville, Va., a post he occupied for 2½ years. At the same time he served as clinical professor of preventive medicine at the University of Virginia. Previously, he founded the University's department of preventive medicine and served 6 years as chairman of the department.

Another appointment in the Office of Vocational Rehabilitation brought Dr. Frank H. Krusen, founder and senior consultant of the Mayo Clinic's section of physical medicine, to the post of special assistant to the director for health and medical affairs. He is on leave from the Clinic.

Dr. Donald Roger Chadwick, a career medical officer of the Public Health Service, has been named secretary of the Federal Radiation Council, on detail from the position of chief of the Program Operations Branch, Division of Radiological Health, Public Health Service, which he has held since July 1, 1958. Before then, he was acting chief of the division for 4 months, having been liaison officer for radiation in the Office of the Surgeon General.

Epidemic Hemorrhagic Fever in Argentina

D. J. GREENWAY, H. R. RUGIERO, A. S. PARODI, M. FRIGERIO, E. RIVERO, J. M. de la BARRERA, F. GARZON, M. BOXACA, N. METTLER, L. B. de GUERRERO, and N. NOTA

A DISEASE of unknown etiology appeared a few years ago in the northwestern part of the Province of Buenos Aires. The clinical aspects were first described by Arribalzaga (1) and later by Duva (2), who suggested that it may be of leptospiral origin. The disease appeared again in 1958, and in May of that year we went to the city of Junín to study its clinical and etiological features. This study was the first to provide evidence of the virological nature of the causative agent (3). Later, Margni and co-workers, on the basis of little evidence, presented the opinion that poisoning by dieldrin, aldrin, or other products, might be an auxiliary factor (4).

At a special meeting held in the University of Buenos Aires on December 19, 1958, we presented a full report of our work with the disease, defining it as new in Argentina and giving additional evidence of its virus etiology (5,6). This work has since been confirmed by other investigators (7).

The clinical descriptions, which we had previously published, were recently confirmed by studies of the disease produced by inoculation of human volunteers. This research was conducted by two groups, working independently, and their reports appeared at about the same time (7,8).

Clinical Characteristics

Argentine epidemic hemorrhagic fever is an infectious disease, attacking principally male

rural laborers with a characteristic symptom complex—renal, nervous, cardiovascular, and hematic. The disease lasts from 10 to 15 days and may end in recovery without sequelae or in the patient's death (9,10).

The onset of the disease is usually gradual, the symptoms making their appearance insidiously. There is general discomfort, asthenia, cephalgia, myalgia, anorexia, saburral tongue, vomiting, alternations in movements, especially in gait, and sometimes slight strabismus. Some cases show palatal enanthema, but exanthema is not seen. The pulse is rapid or normal, the blood pressure tends to be low, and the fever may be moderate or high (40° C.).

Three to five days after onset the symptoms become accentuated. There is marked dehydration, exanthema, and discrete congestion involving the thorax and flanks which may later show petechiae. In some cases there is epistaxis, hematemesis, melena, hematuria, and gingival hemorrhages. The Rumpel-Leede phenomenon is usually positive.

Respiratory symptoms are rare and X-rays are negative. There may be a cough and moist stertorous breathing. The hypotension becomes quite marked, sometimes to the point of collapse.

Abdominal palpation reveals epigastric sensitivity and sometimes a slightly enlarged liver. In some cases there is icterus. Oliguria or anuria is sometimes seen. Nervous symptoms include cutaneous hyperesthesia, muscular spasms, and spasms of the glottis. The patient may become stuporous or delirious.

In cases with favorable evolution, the fever drops rapidly; there is progressive disappearance of the urinary symptoms; and the general condition gradually improves. The patient

The authors are in the department of microbiology and parasitology of the medical school of the University of Buenos Aires, except Dr. Rugiero, who is in the school's department of infectious diseases.

out by the data. Patients with long-term illnesses required more time for each visit of the nurse, needed a greater number of visits, and were served over a longer period than patients with conditions that traditionally have been considered health department responsibility. The secondary problems, such as emotional, economic, and social difficulties, with which the nurse had to deal also varied with the diagnostic category of the patient.

Comparable amounts of nursing service were given to patients in the health supervision, acute communicable disease, and venereal disease categories. Patients in the orthopedic and mental health categories received twice as much service, and those with chronic diseases from three to five times as much.

Teaching about personal and emotional hygiene, normal growth and development, nutrition, the need for medical supervision, and the prevention and control of communicable diseases was the nurses' primary responsibility in the traditional health department programs devoted to health supervision, maternity, acute communicable disease, and venereal disease. Instruction appropriate to the patient's condition for patients in the other diagnostic categories, however, was accompanied by a considerable amount of actual nursing care. For instance, patients with chronic illness, noncommunicable diseases, tuberculosis, or orthopedic conditions required the administration of medications, a variety of other treatments, and, often, general care. In the traditional programs mentioned, nursing care was rarely given on a continuing basis.

Recognition of emotional problems, handling of minor ones, and referral of the more serious ones to sources of adequate care were a regular part of the nurse's job. The types and frequency of occurrence of these problems did not seem to be influenced greatly by the patient's diagnostic category except for patients in the mental health group. Behavior of the patient, family tensions because of the illness, parent-child relationships, and reactions to the physical condition or the medical care needed were problem sources common to all groups.

The same sort of economic problems were consistently encountered in service to patients

in all diagnostic categories. Income inadequate to cover normal necessities, the cost of medical and institutional care and of transportation to that care, and unemployment were reported frequently. While housekeeping assistance of some kind was needed by some patients in all categories, the need was particularly acute for the patients with chronic illness.

The greatest variation among the categories was shown in reports of the types of social problems encountered. With the chronic disease patients, education or language difficulty, community reaction to the patient's condition, and the lack of occupational and recreational facilities were real handicaps. The social problems of unmarried and of deserted mothers complicated the provision of adequate care for them. Eligibility of the patient for medical and institutional care and the existence or absence of such facilities were factors in the adequacy of treatment available to the tuberculosis patients.

Conclusions

In the long-established health department programs, the nurse's job is primarily teaching, with a minimum of nursing care given. The newer programs require, in addition to the teaching, the actual giving of nursing care frequently, consistently, and over a long period of time. This has real implications for agencies which are considering their role in the care of the sick and the extent to which they may offer services.

The study data indicate ranges of volume and types of public health nursing services but are not intended to be used as standards, since local needs determine agency policies and programs which, in turn, influence service. The methods of this study can be applied by any agency to obtain similar data which will reflect its own operating experience. Since the nurse participants in this study used as sources of data the regular health department records of the eight agencies where they were employed, it is reasonable to assume that the same kind of information is available or can be obtained in any agency where public health nursing services are provided.

The first from blood; the second from a suspension of viscera: brain, liver, spleen, and kidney; and the third from urine containing large amounts of blood.

Tissue culture did not propagate viral growth. The hemagglutination test was negative at different pH adjustments using chicken red blood cells from day-old chicks and adults. The virus is inactivated at 56° C., for 30 minutes, and also by ether and by trypsin.

The relation of the isolated virus with the disease was demonstrated by rise in antibody titer (complement fixation and neutralization tests). This relation was also demonstrated by the inoculation of a human volunteer with infected material, thus reproducing the disease, with subsequent isolation of the virus from his blood in the acute stage of the disease. Sero-logic tests were confirmatory in this case.

Epidemiology

Most of the patients are rural laborers, employed in the corn (maize) harvest beginning in April and ending in July or August. Some patients have not been engaged in such activity, but have had some contact with the cornfields. The occupations of 73 patients seen by us during the 1958 epidemic are the following:

Occupation	Number
Corn harvester.....	37
Rural worker (general).....	11
Housewife (rural).....	5
Housewife (urban).....	1
Dairy-farm worker.....	5
Farm supervisor.....	3
Cattle driver.....	2
Rural mechanic.....	2
Tractor driver.....	2
Public road worker.....	1
Veterinarian.....	1
Entomologist.....	1
Rat exterminator.....	1
Hobo (tramp).....	1
Total.....	73

The sex and age of the same group of patients are presented in the table. There is no evidence of interhuman transmission of the infection. The case-fatality rate in that group was 23.28 percent (9).

The field where the patients worked con-

tained large numbers of field mice (*Hesperomys laucha laucha*), which are heavily parasitized with blood-sucking mites. The nests of these rodents are also heavily infested with the mites. It is interesting to note, however,

Sex and age distribution of 73 patients with Argentine epidemic hemorrhagic fever, 1958

Age group (years)	Recovered cases		Fatal cases		Total
	Male	Female	Male	Female	
10-20.....	10	3	1	0	14
21-30.....	13	1	6	0	20
31-40.....	10	3	3	0	16
41-50.....	7	2	4	0	13
51-60.....	4	2	1	0	7
61-70.....	1	0	2	0	3
Total.....	45	11	17	0	73

that no unusual morbidity or mortality in either wild or domestic animals was observed in the district during the course of the epidemic. There is one report (14) of recovery of the virus from arthropods from the epidemic district, but this work awaits confirmation.

Subsequent to the submission of this paper for publication two others appeared with further information on the subject. In one, the authors announced the isolation of the virus from field rodents: several times from *Mus musculus*, once from *Hesperomys laucha*, and once from *Akodon arenicola*. Tests with *Oryzomys flavescens* and *Rattus* sp. were negative (Parodi and others, *Prensa Med. Arg.* 46: 555, 1959). In the other paper, the authors demonstrated the neutralization *in vivo* of the virus with the immune serum of Russian spring-summer encephalitis (Parodi and others, *Rev. Soc. Arg. Biol.* In press).

commences to urinate abundantly but continues to eliminate a large amount of albumen.

In the very severe cases, the patients go into coma of the uremic or encephalopathic type, and die in collapse.

Laboratory Findings

According to findings in the laboratory, the blood picture is characterized by leukopenia, sometimes quite accentuated (400 leukocytes per milliliter), with preservation of normal percentages in the differential count except for the absence of eosinophiles (2,11). There is a marked reduction in platelets, which may reach 20,000 to 30,000 per milliliter. The red cell of the bone marrow reveals hypofunction during convalescence.

Blood chemical findings (glucose, creatinine, bilirubin) are generally normal. Liver function tests, thymol and Hanger, also give normal results. The urea usually increases to 0.60 and to 1.00 percent (urease test). Sodium and calcium levels are low within normal range. Total lipids, cholesterol, and esters decrease, especially in acute cases. Proteins keep within normal values, with slight hypoalbuminemia.

There is moderate albuminuria with marked quantities of cellular and granular casts, and characteristically vacuolated epithelial cells. In many cases with favorable progress, we have observed intense and brief albuminuria for 1 or 2 days toward the end of the clinical phase of the disease.

Postmortem Findings

The pathology of the disease is characterized by injury to the vascular system which is demonstrated by interstitial edema and degeneration of organs, especially the kidneys and liver.

Epithelial cells of the kidney show an indefinite border and granulous cytoplasm, with alteration of the nucleus. Hyaline and blood casts are seen in the tubular lumen. Intratubular hemorrhages are noted. In the epithelial cells of the convoluted tubules, a granular hyaline appearance is observed. The capillaries of the glomeruli are completely filled with blood.

Liver pathology consists of a granular degeneration of the cytoplasm in the hepatic cells. The central vein is dilated, and sinusoids contain a deposit of bile pigment. Edema is observed in the connective tissue surrounding the dilated central vein, as well as lymphocytic infiltration in some of the Kierman spaces.

In the brain there is congestion with marked meningeal edema with some mononuclear infiltration (13).

Microbiological Findings

The search for the causative agent included two different microbiological approaches (3,8,12). In one field of research, bacteria and fungi were considered, while in the other, viruses and rickettsiae were investigated. Negative findings proved this disease not to be of bacterial (including leptospiral) or fungal origin (12). Infectious material was inoculated in mice, rats, guinea pigs, hamsters, pigs, monkeys, embryonated eggs, and tissue culture of monkey kidney, HeLa, and KB cells. Only guinea pigs were infected, as evidenced by illness and death within 15-20 days after inoculation. Necropsy showed the following pathological picture: petechial hemorrhages in the subcutaneous tissue, hemorrhagic abdominal lymph glands, intestines empty with small hemorrhages in the mucosa, hemorrhagic adrenal gland, and general congestion of internal organs. These animals were invariably negative for bacteria and fungi.

A suspension of organs from the infected guinea pigs was inoculated intracerebrally into white suckling mice 24 to 48 hours old. Consistently on the ninth day, disturbance in locomotion, muscular contractions, and, occasionally, paralysis were noted.

Further investigative work proved that the same symptoms could be produced in suckling mice by direct inoculation of original source material. Guinea pigs were susceptible by subcutaneous intraperitoneal and intracerebral routes, but suckling mice by the intracerebral and subcutaneous only. Suckling rats were found susceptible to intracerebral inoculation with brain from infected suckling mice.

As a result of this work, we have now three virus isolates, each from a different patient.

An unusual opportunity for epidemiological study of an outbreak of gastroenteritis was afforded when 171 campers became ill within a 30-day period at a Boy Scout ranch in New Mexico.

Outbreak of Nonbacterial Gastroenteritis at a Boy Scout Ranch

JOHN F. FOLEY, M.D., and TOM D. Y. CHIN, M.D.

NONBACTERIAL gastroenteritis is a self-limited disease characterized by an abrupt onset of nausea, vomiting, diarrhea, and abdominal cramps. The illness may appear sporadically or in epidemics. Most of the knowledge regarding this disease has been derived from studying outbreaks occurring in institutional populations (1-6).

During August 1957, an outbreak of gastroenteritis affecting 171 persons was observed on a Boy Scout ranch in New Mexico. The disease was similar to those previously described as epidemic diarrhea and vomiting or infectious nonbacterial gastroenteritis. This outbreak presented an unusual opportunity to study the disease from two standpoints: (a) to observe the behavior of the disease in four separate susceptible groups of people who came into the area at weekly intervals, and (b) to observe the occurrence of the disease in family constella-

tions. Clinical and epidemiological observations were made in these well-defined populations, and isolation of the virus was attempted.

The Setting

The Boy Scout ranch occupied an area of approximately 177,000 acres in the Sangre de Cristo Mountains. There were three major population centers designated as ranch headquarters, camping headquarters, and training center. The units were located approximately one-fourth to one-half mile apart. Ranch headquarters carried on the administrative affairs and served as the central depot for food, camping supplies, and other general items. After arriving at the ranch, Boy Scouts were quartered in tents at camping headquarters for 1 or 2 days prior to leaving on various camping expeditions in the mountains for the duration of their stay. During the months of June, July, and August, Scout leaders were given special training in the training center for 1 week to enable them to instruct local Scout heads in their respective communities. Tent homes were supplied for their families. Each Wednesday approximately 350 people entered the center and departed the following Tuesday by noon. Also living in the center were 86

Dr. Foley is an epidemic intelligence service officer and Dr. Chin is assistant chief of the Kansas City Field Station, Communicable Disease Center, Public Health Service. Bacteriological assistance was given by Dr. Daniel Johnson, director, public health laboratory, New Mexico Department of Public Health. The virus studies were supported in part by the section of virus research, University of Kansas School of Medicine.

New Course in Chemical Analysis of Water

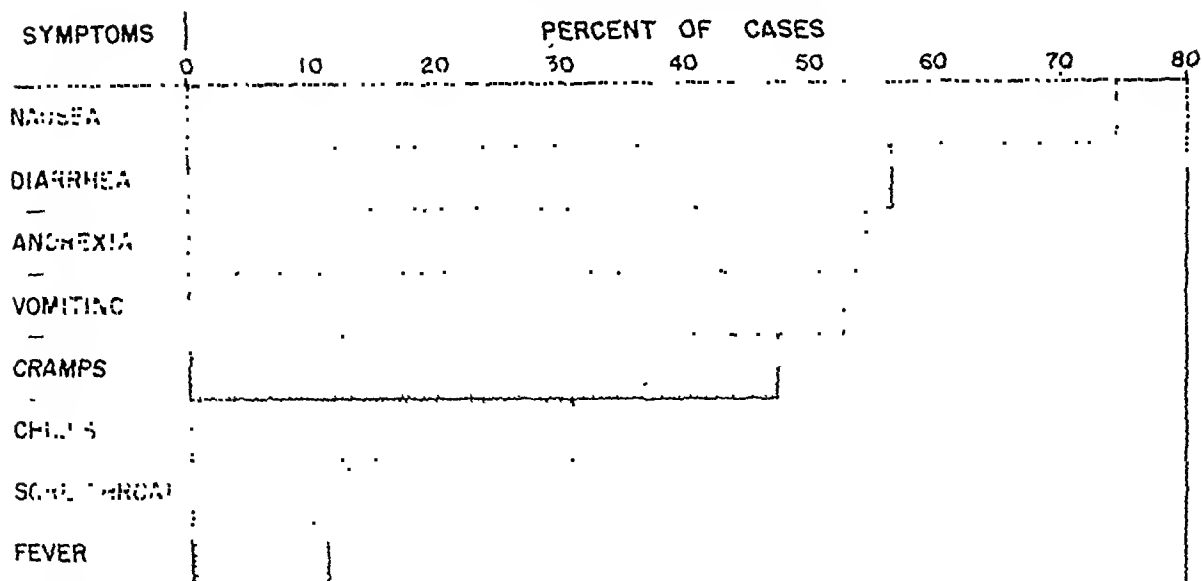

A course entitled "Chemical Analyses for Water Quality" will be conducted by the Robert A. Taft Sanitary Engineering Center, Public Health Service, from November 30 through December 11, 1959. Courses concerned with the same topic have been presented annually since 1949; the current offering, however, represents an entirely new approach. The trainees will study the determinations required at various stages in the life of a typical stream: its origin as a water resource, as it becomes polluted by sewage and industrial wastes, accomplishes self-purification, and again becomes a source of water supply for downstream communities.

Lectures and discussions will cover the types of determinations required, a review of current methods, and research investigations into new analytical procedures. In the laboratory sessions, the appropriate methodology will be critically studied and evaluated for precision, speed, and applicability.

Included on the faculty for this course are members of the research team at the center, as well as consultants from water supply and waste treatment industries.

Applications for the course may be obtained by writing to: Chief, Training Program, Robert A. Taft Sanitary Engineering Center, Public Health Service, 4676 Columbia Parkway, Cincinnati 26, Ohio.

Figure 1. Frequency of symptoms among 55 cases of gastroenteritis, Scout training center in New Mexico, August 1957

Feces and oropharyngeal specimens for viral studies were frozen at -20°C . or -70°C . Feces for bacteriological examinations were preserved in glycerine without refrigeration. Some of the specimens frozen at -20°C . were also studied for the presence of bacterial pathogens. Serums, after being separated from the clots, were stored at -20°C . Since the campers came from all parts of the country, it was not possible to follow them for subsequent illness after they left camp. However, convalescent serums were obtained from certain families.

Bacteriological studies were performed by the laboratory of the New Mexico Department of Public Health, using standard methods for isolation of enteric pathogens. Viral studies were performed in this laboratory using standard tissue culture techniques. The tissue cultures used were HeLa, human amnion and KB cells, and epithelial cells from monkey, guinea pig, and calf kidneys. One-day-old suckling mice were also used. All specimens were passed in suckling mice and monkey kidney epithelial cells at least once. Five to eleven representative specimens were passed two or more times in each of the tissue culture systems except that only primary passage was made in guinea pig epithelial cells. Specimens were examined also for the presence of hemadsorption viruses using

the technique developed by Chanock and associates (7). Guinea pig and chicken red blood cells were used in the test performed at a pH range of from 6.5 to 8.

Bacteriological and toxicological studies were performed on water samples collected from outlets at various sites on the ranch during the latter part of August.

Clinical Observations

The predominant symptoms were nausea, vomiting, diarrhea, and abdominal cramps. The onset was generally sudden; however, in some instances there were prodromes of malaise or slight nausea for a few hours. The sudden onset of vomiting or diarrhea usually ceased as quickly as it started. The patient felt quite well shortly thereafter, but in most cases another bout of vomiting followed 1 to 4 hours later.

The frequency distribution of individual symptoms observed in 55 patients is illustrated in figure 1. The most common symptom was nausea, which affected about 75 percent of the patients. More than half of the patients had diarrhea and vomiting. Vomiting was observed almost twice as frequently in children as in adults. Abdominal cramps occurred in about 47 percent, but chills and sore throat were less

staff members and their families, 76 of whom were employed for the entire 13 weeks and 10 for shorter periods.

The training center consisted of 186 tents each measuring 10 by 12 feet. Each tent was occupied by two persons. Parents and children usually occupied adjacent tents. Occasionally crowding made it necessary for parents to share a tent with one of their children. Also located in the training center were a number of permanent buildings for staff, residences, offices, dining hall, assembly hall, recreation hall, and infirmary. A few campers were housed in private cottages.

The tent area was divided into three parts designated as north tent city, south tent city, and south tent city east end. For ease in identification, these areas will be referred to here as A, B, and C, respectively. Each tent city had accommodations for more than 100 persons. General sanitation was excellent, and each tent city had separate modern lavatory facilities. All foods were prepared in a central kitchen. Residents of cities B and C shared a mess hall, but residents of city A ate in a separate dining area. Staff members ate in either mess hall, as they preferred.

The water used in all parts of the ranch came from a central processing plant. The raw water from the reservoir, formed by damming a creek, was treated by flocculation, sedimentation, and filtration. The purified water was chlorinated to contain 0.4 part per million of available chlorine, and daily records were kept of the tests performed on water samples from various sites on the ranch. Chlorine residuals were adequate during the entire period, and there was no evidence of gross contamination of the water supply.

All foods were obtained from a central commissary. The meat products came from a commercial packer, and pasteurized milk, supplied by a single distributor, was used in all areas.

Sewage from the camp headquarters and the training center was treated in Imhoff tanks, and the primary effluent, after being chlorinated, was further treated by subsurface filtration. Sewage from the ranch headquarters received no primary treatment before emptying into a ditch which drained into an area about one-half mile away.

A medical staff of one physician, three medical students, and two nurses served the ranch population.

Study Methods

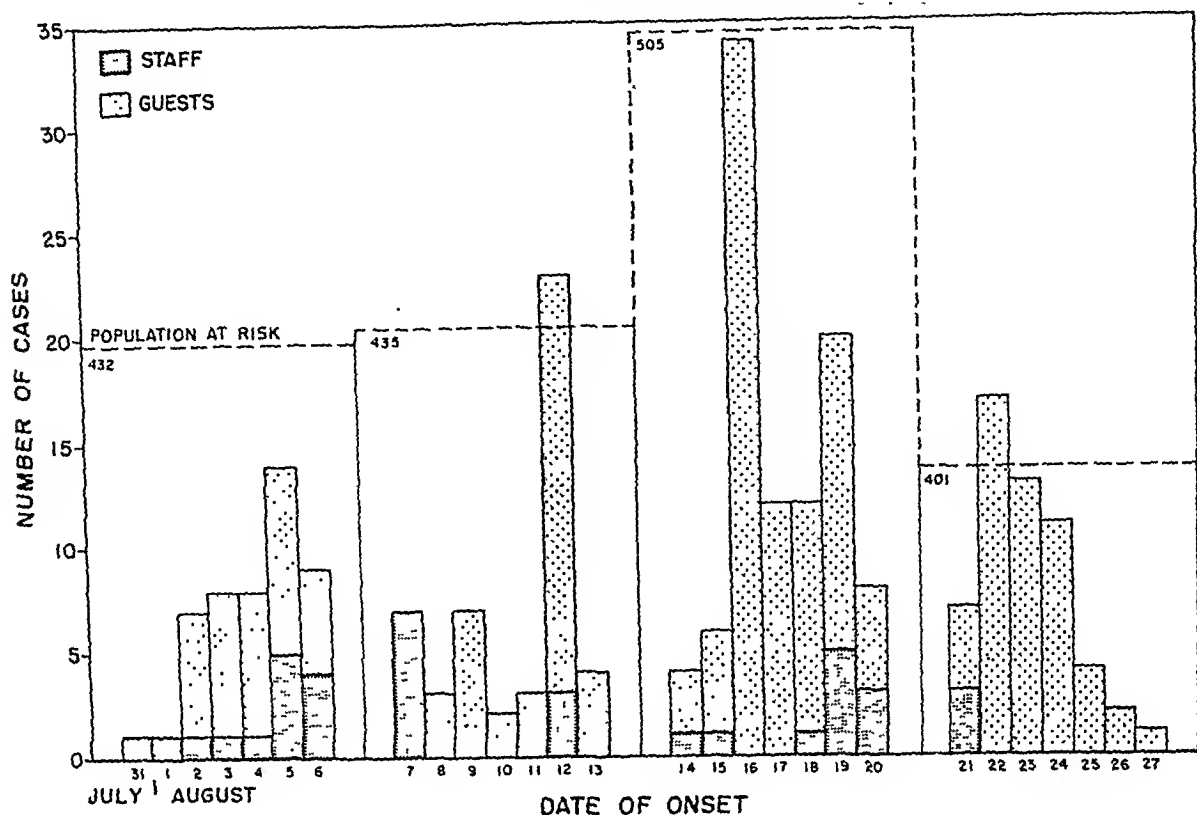

A systematic investigation was initiated on August 21, 1957, 21 days following the beginning of the outbreak, and terminated on August 27. All patients and their familial associates were interviewed and the data were recorded on standard questionnaire forms. All ill persons, upon reporting to the infirmary, were examined by Dr. Foley or by the medical students. Daily records were kept on all persons reporting to the infirmary for treatment. Prior to August 20 a daily logbook was maintained by the nurse in which she listed all persons reporting ill to the infirmary, together with a description of their major symptoms. These records were available for the previous 2 years (table 1).

Specimens for etiological studies, consisting of feces (stools or rectal swabs), oropharyngeal secretions (throat washings or swabs), and acute and convalescent serums were obtained from reported cases and their familial contacts.

Table 1. Reported incidence of gastroenteritis by month, Scout training center in New Mexico, 1955-57

Year	June			July			August		
	Total population	Number ill	Percent ill	Total population	Number ill	Percent ill	Total population	Number ill	Percent ill

1956.....	1,006	7	.7	1,016	3	.3	1,020	7	.7
1957.....	956	10	1.1	1,100	24	2.2	1,459	171	11.7

Figure 2. Incidence of reported cases of gastroenteritis by date of onset, Scout training center in New Mexico, July 31–August 27, 1957

The number of persons reporting to the infirmary for diagnosis and treatment classified by date of onset of illness is illustrated in figure 2. It should be recalled that each weekly population at risk represented a new group of susceptibles, with the exception of the staff members and the group of families which remained over from the third to the fourth week of camp.

More than half of the illnesses in the first three groups occurred toward the end of the week, but the concentration of illness in the fourth group was observed during the first part of the week. The difference in the epidemic pattern observed in the fourth group may be partially explained by the fact that 58 persons who entered the camp during the third week remained

Table 3. Weekly incidence of gastroenteritis by tent city, Scout training center in New Mexico, 1957

Week ending	City A		City B		City C	
	Number persons	Percent ill	Number persons	Percent ill	Number persons	Percent ill
August 6	132	5	119	20	91	6
August 13	141	8	120	13	96	6
August 20	158	15	136	21	112	6
August 27	141	11	87	10	67	10
Total	572	10	462	18	366	7

NOTE: Each weekly population represents a new group of susceptibles. Staff personnel and families in cottages were not included. 58 persons staying from the third to fourth week were not included in the fourth group.

frequent complaints. Fever, with temperature ranging from 99.5° to 101° F., was observed in about 10 percent of the patients, although none was dehydrated. There was considerable variation in the severity of the disease.

Of the 55 patients, 17 had both vomiting and diarrhea, 12 had vomiting without diarrhea, 15 had diarrhea without vomiting. The remaining 11, who had neither vomiting nor diarrhea, had varying complaints but mainly nausea, abdominal cramps, and chills. The stools varied in consistency from pea soup to poorly formed; the frequency of bowel movements ranged from 2 to 25 times per day, with a median of 3. No pus or blood was seen grossly or microscopically. On physical examination, no remarkable abnormality was found. About 10 percent of the patients showed moderate injection of the pharynx, but this finding is probably the result of normal variations in random sampling. Hyperactive bowel sounds were evident on abdominal auscultation.

The average duration of illness was less than 24 hours, although some of the patients were ill for as long as 3 days. The duration of the illness was longer and the symptoms were somewhat more severe in adults than in children. Recurrences of the illness after recovery were uncommon. No deaths or complications were noted during the period of observation.

White blood counts were obtained on five children and five adults. The counts varied from 7,500 to 22,800 per cubic millimeter, with a median of 13,200. The number of leukocytes per cubic millimeter was higher in children than in adults, and the higher counts were associated with an absolute increase in the number of polymorphonuclear leukocytes.

Epidemiological Studies

An increase in the incidence of gastroenteritis was observed during the first week of August 1957, and abnormally high rates continued until the camp closed in the first week of September. The first case of gastroenteritis was noted, among a new group of persons who arrived on July 31, in a 2½-year-old child who became ill approximately 3 hours after arrival. On the following day, a similar illness was noted in a 5-year-old sibling of this child. On

the third day, five additional cases were observed among other families living in the same area.

Of 1,457 persons attending the Scout camp for 1 or more weeks during the month of August, 171 experienced an attack of gastroenteritis for an overall attack rate of 12 per 100 persons. This rate was considerably higher than the rates of the preceding months of June and July (table 1). Although the rate observed for July was higher than that of June or any other month during the preceding 2 years, the illnesses observed were scattered at random throughout the month with no abrupt peaking of cases in any one week. It appears, therefore, that the slight increase in incidence of gastroenteritis during July probably represents variations in seasonal incidence rather than cases occurring during the early phase of the outbreak in August.

The weekly incidence of gastroenteritis observed among campers staying only 1 week between July 31 and August 27, 1957, is shown in table 2. The attack rates ranged from 9 to 16 with an average of 12 per 100 persons. The highest rate was observed during the third week, when there was the greatest camp population. Attack rates were significantly higher among staff members and members of those families staying at the camp for at least 2 weeks. The rate for the staff members was 42 per 100 persons (36/86) and that for families staying at the camp for 2 weeks was 40 per 100 persons (33/58).

Table 2. Weekly incidence of gastroenteritis occurring at Scout training center in New Mexico, 1957

Week ending	Number persons	Number ill	Attack rate (percent)
August 6.....	342	35	10
August 13.....	357	33	9
August 20.....	406	63	16
August 27.....	295	33	11
Total.....	1,400	164	12

NOTE: Each weekly population represents a new group of susceptibles. Staff personnel and families in cottages were not included. 58 persons staying from the third to fourth week were not included in the fourth group.

gans. Neither 3-week-old mice nor various tissue cultures, including monkey kidney epithelial cells, HeLa cells, and human amnion cells were affected by the agents.

Cytopathogenicity was not observed in any of the tissue culture systems following inoculation of a selected number of specimens. A total of 28 specimens inoculated into monkey kidney epithelial cells and 25 specimens into calf kidney epithelial cells were tested for the presence of hemadsorption virus. No hemadsorption was observed under the conditions previously mentioned over a period of observation varying from 7 to 40 days.

Ten water samples obtained from outlets in various areas on the ranch during the course of the epidemic were tested for bacterial contamination. Coliform organisms were not detected in any of the samples. Also, two water samples tested did not reveal excessive amounts of inorganic compounds normally found in water or other inorganic substances that are capable of causing diarrhea.

Discussion

The clinical entity referred to as acute infectious nonbacterial gastroenteritis is an exceedingly common disease. It has been found by Hodges and associates (8) in a family study that gastrointestinal disorders are second in incidence to respiratory diseases. Gastrointestinal disorders consist mainly of cases of acute infectious nonbacterial gastroenteritis.

This disease usually begins abruptly with anorexia, nausea, vomiting, and diarrhea in varying combinations. Headache, fever, and leukocytosis may occur in some instances. On physical examination the distended colon can often be palpated and borborygmi can easily be heard. The disease is self-limited and of short duration. The more severe cases, particularly those in the older age group, may be complicated by dehydration, collapse, and, rarely, death (4, 5, 9). Although this disease may occur throughout the year, the peak incidence is in the fall and winter months.

The clinical picture observed in the present outbreak is consistent with that of acute infectious nonbacterial gastroenteritis as reported in other studies (1-6, 9). It is notable that

about 10 percent of the patients observed in this outbreak complained of sore throat. Whether these symptoms represent an integral part of the clinical picture of nonbacterial gastroenteritis or whether they merely represent a coincidental finding is difficult to determine, although several workers (2, 10, 11) have reported an increase in frequency of throat symptoms. Symptoms related to the respiratory system were not observed in this study. Fever was present in about 10 percent of the cases.

Attack rates among persons attending this camp were considerably lower than those reported in outbreaks of similar illnesses. The frequency of illness was undoubtedly related to the duration of exposure and the duration of observation. The incidence of gastroenteritis among campers staying 2 weeks and the permanent staff was more than three times higher than it was among campers staying 1 week. The attack rates in the former groups corresponded well to those reported in other outbreaks (6, 12) in which the period of observation was longer than 1 week. This relationship was reflected also by the secondary attack rates observed among family contacts. Secondary attack rates among campers would undoubtedly have been higher if it had been possible to follow the patients after they left camp. In a similar study made by Smillie and his co-workers (12), the secondary attack rate was found to be 43.7 per 100 persons. This rate was slightly higher than that observed in the families of staff members and in families staying 2 weeks at the camp.

Nonbacterial gastroenteritis is probably caused by a number of different viral agents. The assumption that some of the outbreaks described in the literature were due to viral agents is based on studies performed on human volunteers using fecal filtrates from patients with nonbacterial gastroenteritis as inoculums. Two immunologically distinct agents have been delineated, namely, the so-called Marcy and FS strains. The Marcy strain was isolated from a typical outbreak of gastroenteritis which occurred at Marcy State Hospital near Utica, N.Y., in 1946 (9); the FS strain was isolated from a patient with nonbacterial gastroenteritis

Table 4. Weekly incidence of gastroenteritis in tent cities by major age groups, Scout training center in New Mexico, 1957

Week ending	Under 18 years			18 years and over			Total		
	Popu- lation	Num- ber ill	Percent ill	Popu- lation	Num- ber ill	Percent ill	Popu- lation	Num- ber ill	Percent ill
August 6.....	167	26	16	175	9	5	342	35	10
August 13.....	190	15	8	167	18	11	357	33	9
August 20.....	186	31	18	220	29	13	406	63	16
August 27.....	139	18	13	156	15	10	295	33	11
Total.....	682	93	14	718	71	10	1,400	164	12

over during the fourth week; 10 of these 58 persons became ill during the first 2 days of the fourth week. Thus it was entirely possible that these 10 cases served to spread the disease widely among persons in the fourth group so that there were almost no susceptible persons by the middle of the week.

Shown in table 3 are the attack rates by tent city for each of the 4 weeks. During the first 3 weeks the incidence was significantly higher among persons living in city B than those living in the other two tent cities. During the fourth week the attack rates in persons living in the three tent cities were approximately the same. It is noteworthy that when the space between occupied tents in city B was increased during the fourth week, the incidence of gastroenteritis declined to that approximating those of the other tent cities.

Attack rates by age for the four groups are summarized in table 4. Incidence per 100 persons among those under 18 years of age was 14 as compared with 10 among those 18 years of age and older ($P=0.02$). This difference was particularly evident in the first group (week ending August 6), in whom the rate among children was more than three times that among adults. There was no difference in the sex distribution.

Multiple cases in families were common. The secondary attack rate among 371 familial contacts of those families staying only 1 week at the center was 15.4 per 100 persons. The average secondary attack rate among the families of staff members and families staying in the center for 2 weeks was significantly higher than that of the former group; of the 43 famil-

ial contacts in the latter group, the secondary attack rate was 37 per 100 persons.

All but 4 of the 57 secondary cases observed in families staying only 1 week at the center developed within 2 days after onset of the index case. Since the time interval between onset of first and secondary cases was so short, it is difficult to say whether these secondary cases were true secondary illnesses or whether they were co-primary cases acquired from the same source as the primary cases. Seven secondary illnesses in staff families occurred within 48 hours of the primary case.

Etiological Studies

Stools obtained from 11 patients were examined for presence of pathogenic bacteria and parasites. Enteric pathogens were not detected in any of the specimens.

Specimens obtained from 27 individuals were examined for the presence of viral agents. These consisted of 20 throat washings and 29 fecal specimens. All the specimens were tested in suckling mice and in various tissue culture systems mentioned previously. A total of four viral agents were isolated from two persons of the same family by inoculation of specimens into suckling mice. Two of the agents came from throat washings and the other two from fecal samples. The agents, although not definitely identified, probably were Coxsackie viruses of group A. All four agents, when inoculated into suckling mice, caused flaccid paralysis followed by death. Histologically extensive degeneration of the skeletal muscles was noted, with no lesions found in other or-

- gastrointestinal symptoms. *Am. J. Hyg.* 64: 349-356, November 1956.

Symposium on Venereal Diseases

The 11th Annual Symposium on Recent Advances in the Study of Venereal Diseases will be held April 7 and 8, 1960, in the Palmer House, Chicago, Ill. The sessions are open to all physicians and workers in this and allied fields who are interested in the venereal diseases.

Sponsored jointly by the American Venereal Disease Association and the Public Health Service, the symposium will follow a venereal disease seminar for public health personnel which begins April 4.

Persons wishing to present scientific papers on subjects related to venereal diseases should mail preliminary abstracts before November 25, 1959, to Dr. William J. Brown, Program Committee Chairman, in care of the Venereal Disease Branch, Communicable Disease Center, Public Health Service, 50 Seventh Street, N.E., Atlanta 23, Ga. These abstracts should give information sufficient to assist the program committee in making a decision as to acceptance or rejection of the papers. Authors of accepted papers will be notified before January 15, 1960. Final abstracts not exceeding 500 words will be required by March 1, 1960.

by Jordan and associates (13) in their Cleveland family study. Although these strains have been incriminated as etiological agents of nonbacterial gastroenteritis, they have not been cultivated as yet in the laboratory using various laboratory animals, media, and tissue culture cell lines (12,14-16).

The etiological agent causing this outbreak remains undetermined. The four Coxsackie-like viruses recovered from two members of a family undoubtedly represent coincidental findings and are not the principal cause of the outbreak. Pathogenic bacteria and amebas were excluded as causative agents on the basis of negative stool examinations and on the basis of clinical and epidemiological studies. The possibility that excessive amounts of inorganic substances were present in the drinking water was eliminated by appropriate tests performed on water samples collected from various points in the camp.

The mode of transmission of viral gastroenteritis has been a subject of considerable research. Early in the experimental work with human volunteers, Reimann and associates (17) reported that they were successful in transmitting the disease by aerosol spray with fecal filtrate obtained from patients with gastroenteritis. However, these investigators were unable to induce the disease in volunteers by ingestion of the same filtrate. Since that time, several other groups of workers (9,13,18, 19) have successfully transmitted the disease by feeding bacterial-free fecal filtrates to human subjects although no one has been able to confirm Reimann's original report relating to respiratory transmission. While it may be possible to transmit nonbacterial gastroenteritis by the respiratory route, the above experimental evidence seems to favor the fecal-oral route as the principal mode of transmission.

The data presented here are insufficient to establish whether the present outbreak was transmitted by the fecal-oral or respiratory route. It is quite certain, however, that the principal mode of transmission is by person-to-person contact. There was no evidence that the outbreak was caused by a common source either on the basis of the epidemiological data or on thorough examination of the water, milk, and food supply.

Summary

An outbreak of gastroenteritis affecting 171 of 1,457 persons occurred at a Boy Scout ranch during a period of 1 month. The clinical characteristics were similar to those described in acute infectious nonbacterial gastroenteritis. Four separate susceptible groups were involved in the epidemic. The attack rates varied from a low of 9 percent in campers staying 1 week to a high of 42 percent in staff members. Attack rates were significantly higher in children. Multiple cases in families were commonly observed. Secondary family attack rates varied from 15.4 percent in those families staying 1 week to 37 percent in the staff families and campers staying more than 1 week.

Laboratory studies for enteric pathogens were negative. Viral studies using suckling mice, various tissue culture lines, and hemadsorption techniques failed to uncover an etiological agent.

SOCIAL PATHOLOGY

IN its 80th year, the Massachusetts Public Health Association at Amherst, September 2, 1959, offered a fresh if not entirely new wrapper for the traditional package of public health.

With Dean Clark, M.D., general director, Massachusetts General Hospital, presiding, a panel of four discussed social pathology and its implications in epidemiology. After an introduction of the subject by Raymond F. Gould, Ph.D., of the National Institute of Mental Health, Public Health Service, Leon Sternfeld, M.D., commissioner of the Cambridge Health Department, suggested broad applications of knowledge of social pathology to public health practice. Other specific examples were provided by Robert Morris, associate professor of the Graduate School for Advance Studies in Social Welfare at Brandeis University, with respect to dependency; and by the late Kenneth W. Chapman, M.D., formerly associate director of the Clinical Center, National Institutes of Health, Public Health Service, speaking of studies of addiction to narcotics.

The Dynamics

Observing that the obvious symptoms of social pathology are found in records of crime, delinquency, family disintegration, alcoholism, and poor working habits, Gould suggested that social health "is to perform so as to survive and to anticipate changes which may threaten survival." For example, he said it is socially healthy to take preventive action against the anticipated effects of atomic warfare, urban sprawl, or overpopulation. It is also socially healthy, he suggested, to develop methods of

satisfying such universal human needs as physical maintenance and protection; the need to make the most of one's self; the need to relate with others competently; and the need to see things as they really are, well enough to manage affairs and to move in new directions, if necessary.

Assuming that an infant can develop in any direction, given nurture, support, and control by family, neighborhood, and government, Gould asserted that when proper nurture, support, and control are lacking, social pathology sets in.

To illustrate his thesis, he described a fictional tribe of Bongo-bongos, living in an economy of scarcity, with an average life expectancy of 30 years, subject to chronic famine and war, where each individual's identity depended either on fighting or food gathering. In such a system, the aged were discouraged: it was cheaper to bury them than to keep them. With a simple model of parenthood, education for girls consisted of learning to be a wife and mother, and for boys, to be a farmer and fighter. Deviants, unsuited to such roles, did not survive. Under the necessities of their condition, however, the Bongo-bongos were socially healthy: as a tribe, their survival value was high.

In contrast, he noted, the complex demands of today's America require long training and advance planning for youth. Although deviants are protected, they are not helped to satisfy their basic needs. Many receive only custodial care at best, and most are on a bare subsistence budget. The elder members of society, although they are preserved, are neglected; an increasing number of unhappy, inadequate citizens. To waste such human resources while

Experience of First Admissions to State Mental Hospitals

This study represents the cooperative effort of the statistical officers in 11 states in the Model Reporting Area for Mental Hospital Statistics and the Biometrics Branch, National Institute of Mental Health. The project, which grew out of a desire to compare data on the flow of patients into and out of the mental hospitals of the various States, had four major objectives. The first was to illustrate the mechanics and problems of conducting a cooperative study among 11 individual governmental organizations, widely separated geographically, where the study focuses on a complex problem requiring careful definition and analysis. The second was to present data on the probabilities of release, death in hospital, and continuous hospital residence for specified periods of time following first admission for different State mental hospital systems. The third was to emphasize the ways in which the basic data differ among States and to discuss the problems of interpreting interstate differences resulting from the incomparability of these data. The fourth was to delineate types of data, methodology, and special studies needed to obtain meaningful interstate comparisons.

The data presented indicate great variability among States in proportions of first admissions released, dying, or retained continuously in the hospital during the first year following admission. However, the primary emphasis of the monograph is on a discussion of the complex intra and extra hospital factors that affect interstate comparisons of the data. These factors include legal categories of admission, severity of illness at admission, population characteristics of the States, policies of the hospitals which affect admission or release, and the use of general hospitals, outpatient psychiatric clinics, and other community psychiatric facilities. As the discussion of these factors develops it becomes increasingly clear that the probabilities of release, death, and retention in the hospital

as presented in the monograph cannot be used as indexes of the therapeutic efficiency of the State mental hospital systems.

The authors discuss statistical adjustments of probabilities of release and death which would take into account the effect of the factors mentioned above. They emphasize that to refine further interstate comparisons of these probabilities studies are needed to determine the level of community adjustment of patients released from the hospital and the rate at which these patients return to the hospital. In these investigations it is extremely important to study the State mental hospital in relation to the entire range of facilities in the community for the care of psychiatric patients.

Public Health Monograph No. 58

Patterns of Retention, Release, and Death of First Admissions to State Mental Hospitals. By Earl S. Pollack, Philip H. Person, Jr., Morton Kramer, and Hyman Goldstein. Public Health Monograph No. 58 (PHS Pub. No. 672), 54 pages, illustrated. U.S. Government Printing Office, Washington, D.C., 1959, price 40 cents.

The accompanying summary covers the principal contents of Public Health Monograph No. 58, published concurrently with this issue of Public Health Reports. With the exception of Dr. Goldstein, who is with the National Institute of Neurological Diseases and Blindness, the authors are with the National Institute of Mental Health, Public Health Service.

For readers wishing the data in full, copies are on sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. Official agencies and others directly concerned may obtain single sample copies without charge from the Public Inquiries Branch, Office of Information, Public Health Service. Copies will be found also in the libraries of professional schools and the major universities and in selected public libraries.

With due regard for the importance of physical or emotional dependency, or the general interdependence of human society, he confined the bulk of his remarks to economic needs.

A typical economically dependent person at the end of the 19th century, he said, was the orphan, served by orphanages and charitable funds set up to provide aid for mothers. The needs of orphans helped to inspire milk stations and other preventive health services which preceded many modern programs and played a great part in reducing orphanage.

Full orphans have almost disappeared, making up less than 0.1 percent of the child population. The number of children bereft of one parent has been reduced by between one-sixth and one-third in the past 25 years alone. Their needs are met mainly by the Social Security Administration program of aid to dependent children.

Chronic illness and aging today produce dependency at the other end of the life cycle, he added. Parents do not die young and leave dependent children, but survive to become dependent in their later years. Of 500,000 families on public assistance in New York State in 1958, he said, only 10 percent were able to work. Most are chronically ill and often they are bedridden, he said, for lack of adequate rehabilitation services. In many government hospitals, he stated, one bed in five is occupied by a long-term patient for social, not medical reasons. And this improper use of hospital beds he laid to inadequate use of social resources—nursing homes, home care programs, boarding homes, and other social services.

He recommended increasing services to the homes of the dependents, with emphasis on rehabilitation. Specifically, he cited the example in Chicago of collaboration by public health officials, public welfare services, and general hospitals, concentrating on nursing home patients receiving old age assistance. In one situation he described, three-fourths of the inactivated patients were able after 1 year to take care of their own physical needs, thanks to combined medical and social services.

The success of such a program for aged dependents, he said, rests on confidence in its success, a comprehensive provision of health,

rehabilitation, and social services; continuity of care; and coordination among agencies in a community organized so as to mobilize its social resources.

Addiction

The social pathology of addiction to drugs and alcohol, Chapman observed, characteristically but not invariably is associated with a hostile environment, dependency, poverty, an unstable or broken home, crowding, and racial handicaps. But while about half of the alcoholic addicts may perform productive work, he said, drug addicts are much less useful. Drug addiction also is less tolerated in this country, he added, than alcoholism. Social attitudes, therefore, have tended to encourage segregation or incarceration of drug addicts. The laws on addiction generally are at least as punitive as therapeutic. The forces behind addiction are seldom understood by families or associates of the victims, and still less do untrained persons understand how to manage addicts, he said. On the contrary, the attitudes of family members may constitute a specific force behind the impulse to take drugs or alcohol.

In the management of addiction, he said, social attitudes are of key importance. All hands are needed to help in rehabilitation of addicts if rehabilitation is to succeed. And that achievement, he said, implies much more education of the public and far better scientific knowledge of the nature of addiction.

Referring to an effort by the Public Health Service to evaluate its work at the Lexington hospital for narcotic addicts, he reported that investigators followed up more than 1,800 patients discharged to the New York City area between July 1952 and the end of 1956. In the course of the effort to learn the fate of these former patients, it appeared that many needed continuing support. On their own initiative, the investigators undertook a long-term rehabilitation program for a few. Without such continuing support for the social and emotional needs of the narcotic addict, Chapman said, the chances are slim that the task of rehabilitation so well begun in the hospital will carry through for long.

we compete with other societies which are stressing productivity and the common good, he said, is a dangerous extravagance.

Other factors in the failure to develop survival values, he observed, are the lack of emotional care for children of middle-class urban parents, largely distracted by the pressures of meeting occupational obligations or the physical demands of an overwhelming technology. Lacking a stable value system in the home, school, or church, he said, young people feel life is meaningless and that the world has no place for them. In his opinion, urbanization in itself deprives society of the social controls and support which individuals find in the rural setting, where the individual is relatively prominent and well-identified. To offset these pathological developments, Gould concluded, public health agencies have a major responsibility, since anticipatory action is the price of survival.

Applied Knowledge

Sternfeld cautioned the attentive audience against a glib approach to social issues. Winslow's definition of public health as social well-being, he said, is an objective, rather than a condition; but it is also more than a pious hope. It has the wisdom of seeing that low rates of morbidity and mortality will not by themselves achieve this objective. "Your agency will fail if it seeks to reform the world," he said, "but neither can you say that social pathology is no concern of ours." As he was about to name specific points of attack, he remarked, "I can hear the public health nurse saying, 'What! Something else added to the caseload!'" But he proceeded to suggest that nurses and sanitarians are in a strategic position to share information on housing and family conditions which breed social pathology. "Liquidation of the physical slum is futile," he said, "if the relocated family is certain to create a new one."

Equally futile, he added, is transfer of a family from a condemned house to a worse one. The correction of housing defects at a cost reflected in rent increases, which simply drives out the present occupants, may be self-defeat-

ing, he explained. Such conditions, he said, demand concerted action by all agencies concerned.

He mentioned venereal disease as another familiar public health responsibility associated with social pathology, differing from other infections in its profound social and psychological implications. (This specific topic was discussed at another session by Dr. Nicholas Fiumara, director of venereal disease control, Massachusetts Department of Public Health.)

With respect to a third conventional field of public health work, tuberculosis, Sternfeld emphasized the social needs of patients in custody, and their management and reception in the community after discharge. The frequency of alcoholics in the tuberculosis wards also calls for an attack on social causes, he added.

As to maternal and child care, he proposed a concentration of efforts upon the most susceptible elements of the population, asserting that the differential rates of maternal mortality by neighborhood in many cities is not ordinarily known, and that the frequency of stillbirths, premature births, and infant deaths is certainly higher in handicapped families; the socially, economically, and emotionally handicapped.

Such handicapped families, he said, tend to be regarded as social lepers, as once were patients suffering from tuberculosis or cancer, and as are mental patients or patients with venereal infections, to some degree, today. On the principle that a multiplicity of needs warrants a multiplicity of services, he proposed that health agencies and others concerned focus upon such special risk groups. Sternfeld predicted that the results would be commensurate with the effort. And he expressed confidence that the effort could overcome the stubborn barriers of ignorance, cultural prejudices, and the current deficiency of facilities and services. Offering no magic recipes for the attack on social pathology, he said that available knowledge can provide useful recommendations.

Dependency

Recommendations for action on dependency were expressed by Morris, after a backward look at the evolution of maternal and child care.

The Importance of Vital Records in Today's Society

HAZEL V. AUNE

A RECENT issue of a popular national magazine (1) described what is to date probably one of the most dramatic uses of marriage and death records. Entitled "A Most Valuable Accident," it is the story of the people who swallowed varying amounts of radium during World War I and on into the thirties. Most of them were the girls who painted the radium figures on watch dials. They found that their work went faster and more accurately if they licked their paint brushes to a point. A number of them died in the early nineteen twenties. Others have died since, but many are still alive.

The Atomic Energy Commission, as a part of its program of collecting all available information about the effect of radioactivity on human beings, is searching systematically for the survivors. The research team provided by the New Jersey State Department of Health, together with a detective from the State police are, in essence, conducting a "missing persons" search to track down and study the dial painters. To trace them, all available records are used. Marriage records are reviewed by the clerks of the vital statistics office in an effort to learn the present names of some of the girls. Death certificates are checked, not only to preclude vain hunts but also to learn presumed causes of death. This is a logical and practical use of vital records.

Most people take vital records for granted; assume we have always had them and, without much effort, will continue to have them available when we need them. The real story is quite different. It has taken more than 300 years to build our registration system. Even

today some vital events escape the registration network. For example, 11 areas have no centrally filed marriage records and 16 areas, no divorce records.

Looking backward, perhaps it is fortunate that our early settlers, predominantly English, were accustomed to the registration of christenings, marriages, and burials. This custom, no doubt, had its part in influencing the Grand Assembly of Virginia in 1632 to require ministers or wardens from every parish to provide at court on June 1 each year a register of christenings, marriages, and burials (2). These were the traditional events conducted by the church, but, in effect, they provided an account of births, marriages, and deaths.

In the beginning, the records were primarily for the protection of individual rights, especially those rights relating to the distribution of property. The emphasis on vital records as legal documents to protect both the individual and the community was first reflected in the 1639 law of the Massachusetts Bay Colony. The law departed from past practice by requiring government officers rather than the clergy to record births, deaths, and marriages (3), and formed the pattern for the laws adopted by Connecticut and New Plymouth, and, eventually, other colonies.

None of the early laws was particularly effective.

Mrs. Aune is chief of the National Consulting Service, National Office of Vital Statistics, Public Health Service. The article is based on a paper she gave at the 27th annual meeting of the Southern Branch, American Public Health Association, at Miami, Fla., on May 27, 1959.

Greek Chorus

In the role of a Greek chorus, the chairman and others provided several supplementary items at intervals for consideration by the audience.

There are now approximately as many beds in nursing homes as in general hospitals.

About 1,000 new persons are added each day

to the number of people in this country who are more than 65 years old.

Old-Age and Survivors Insurance today is paying benefits to more than 10,000 persons who are more than 100 years old.

One marriage in four ends in divorce.

The number of alcoholics in this country is estimated at 5 million; mental patients, 15 million.

Nursing Traineeship Program Extended

Expanded opportunities to increase skills in management of nursing services are available to nursing supervisors, administrators, and teachers. Federal funds have been set aside to enable key personnel in the nursing profession to attend short-term intensive training courses. The Division of Nursing Resources, Public Health Service, will award grants to the institutions or agencies giving the training courses.

The program is an extension of the professional nurse traineeship program which for the past 3 years has supported traineeships for nurses preparing for supervisory, administrative, and teaching positions in colleges and universities. Legislation continuing the program for 5 years has been passed by the Congress.

Short-term traineeships will be limited to graduate professional nurses now employed as administrators, supervisors, or teachers, for whom advanced full-time study is not now possible. The grants will cover tuition and fees for the course plus a stipend when necessary.

The Public Health Service must approve plans for any institution or agency to supply the new training courses. Criteria for participation are available from the Division of Nursing Resources.

Traineeships for nurses enrolled in full-time academic programs will continue to be available.

and death certificates when in 1900 the APHA committee on demography was preparing a set of basic principles to guide States in preparing laws for the registration of deaths and the collection of mortality statistics. These principles, together with the first standard certificate of death, were adopted by the Bureau of Census in 1902, and were published in a circular (11) which was sent to the governor of each State, medical societies, journals, and others interested in registration. This document was extended in 1903 to cover the registration of births and included the first standard certificate of birth (12).

The broad registration principles were prescribed in the first model law of 1907. The model law gave the State boards of health central authority over registration matters, listed the items for inclusion on State certificates, specified responsibility for registering births and deaths, provided for the establishment of local officials and for the issuance of burial permits, and called for enforcement of the law. The major new items introduced in subsequent revisions of the law include marriage and divorce registration, a standard certificate of fetal death, provisions for delayed registration and alteration and amendment of vital records.

Although every State had passed registration laws (13) of a sort by 1911, the Bureau of the Census did not create the national birth registration area (14) until 1915. By then, the death registration program was established on a firm basis. In 1933, for the first time, both the birth and death registration areas included all States. Only since that year have the annual vital statistics publications been based upon data from the entire United States.

This does not mean there were no vital statistics published from 1900 to 1933. The annual collection of mortality statistics began in 1900. The first published report combined in one volume the statistics for the 5-year period 1900-04 for the States and cities in the death registration area. However, no birth statistics were published by the Bureau from 1900 until 1915. The earliest statistics on marriages and divorces for the 20-year period 1887-1906 were obtained from a survey by the Census Bureau; in addition, some 1867-86 data were summarized from an earlier survey by the Commissioner of

Labor (15). Similar surveys and, on occasion, more systematic collections provided intermittent publication of limited marriage and divorce statistical data until 1949, when the National Office of Vital Statistics began a program of detailed statistics based on State tabulations. The registration area for marriage was established on January 1, 1957, and, for divorce, on January 1, 1958. Just when all States will be included in these areas is the major question of the registration system today.

Lest I may have given the impression that registration of vital events, and more particularly of births, was motivated primarily by officials interested in their use for statistics, note S. N. D. North's quotation (12) of Dr. John S. Fulton on the direct interest of the individual citizen in 1903:

"The private interest of the citizen in registration of births is indeed superior to his interest in registration of deaths, for a greater proportion of his privileges and immunities, rights and duties, turning upon the question of his age and his parentage, are definitely conserved by the registration of his birth.' Some idea of the frequency with which questions arise requiring reference to the records of births may be gained from the fact that the calls for copies of records or for information contained in them in New York City during the year 1902 exceeded 3,000."

Of course, this is only a tiny fraction compared with the hundreds of thousands of copies of birth, death, marriage, and divorce records issued and used for various purposes today. But the use of vital records even in 1902 demonstrates that our registration and statistics system came about not by mere chance but in response to demands for records as well as statistics. The need for legal documents with evidentiary value increased greatly as society became more complex and man began to be required to prove his right to his name, his citizenship, and his place in society.

Each day society is creating new and increasing demands on the vital records system. As medical advances are made, for example, vital records grow in importance and more and more data are sought through the records.

Sirken and Dunn (16) have discussed the development of sampling survey methods and

tive in promoting registration, probably because practically the entire justification for maintaining a registration system was the legal and historical use that could be made of the records.

For the next 200 years, nothing of significance was done to make registration more effective. During this time death lists and burial returns were occasionally used as a means of recognizing and fighting epidemics, or for reporting on health conditions in a given community.

Early in the 19th century, a few statisticians and medical men began to realize that records of births and deaths, particularly records of deaths by cause, were needed for the control of epidemics and the conservation of human life. In 1812 Massachusetts passed the first "modern" registration law (4). As revised in 1844, the law provided for uniform certificates to be used throughout the State and for the establishment of a statewide file of copies of the records.

At about this time national organizations first took a direct interest in registration. Among them was the American Medical Association, which in 1847, the initial year of its organization, appointed a committee to study ways and means of improving the registration of births, deaths, and marriages (5). Several years later, the association formally urged physicians throughout the country to request their States to establish offices for the collection of vital statistics.

How were statistics compiled at that time? The first effort to collect national birth and death statistics occurred in 1850. One hundred years ago, in 1860, when the Nation's population was nearly 31.5 million, the marshals of the U.S. Census Office enumerated less than 1 million infants under 1 year of age and less than half a million deaths (6). Now, a century later, our population is almost six times greater; more than 4 million births and over 1.5 million deaths are recorded annually. Marriages and divorces, combined, account for nearly 2 million more vital events (7).

Admittedly, in 1860, the marshals knew that more babies were being born and many more people were dying, but had to rely on the memories of their informants. There is abundant evidence that vital events were recalled and re-

ported in proportion to the recentness of occurrence. Furthermore, no record was made and no account taken of those who died in taverns, boarding houses, on shipboard, in boats on rivers, and so on. With such reporting deficiencies, it is not surprising that the apparent death rate varied from approximately 5 per 1,000 in Washington Territory, to 21 per 1,000 in Arkansas. Enumeration totals were actually compared with the death record totals in the seven States which required birth and death registration in 1860. In three States the marshals discovered a smaller number of deaths than were reported by the State authorities, and, in the other four, they discovered and reported more (8).

Despite the inadequacies, birth and death figures for the entire country were compiled largely from the reports of the census enumerators through the 1900 census because the only alternative was no national statistics at all. Meanwhile, however, aware that vital data could be satisfactorily collected only by the registration method, the Census Office established the "registration area for deaths" in 1880 (9). As a matter of fact, in certain large cities where a complete death registration system based on burial permits was in operation, no data on deaths were collected by the enumerators in 1880, 1890, and 1900. The records from the central registration offices of these cities were used instead (10).

In 1902, the Bureau of the Census was made a permanent agency by an act of Congress. The act authorized the director of the Bureau to obtain copies of records filed in vital statistics offices of such States and cities as, in his discretion, could provide satisfactory data. To develop a collection system capable of producing comparable statistics on a national basis required uniformity with respect to such matters as laws, forms, and procedures. Numerous organizations cooperated with the Bureau in tackling and accomplishing this task.

The American Public Health Association had been actively promoting uniform State registration and model laws for many years. In fact, in 1895 members of the association had proposed that it either draft a model law or set forth principles. No two States and few cities were using precisely the same forms of birth

conduct of studies to collect supplementary statistical data "anchored to vital records." Their paper described the Pennsylvania mortality study, the methodological study undertaken primarily to develop procedures of collecting information to supplement data contained in death certificates. The study also served as a pilot test for an epidemiological lung cancer study.

A paper on residence history of deceased persons was presented at the recent Population Association meeting at Providence, R.I. And a survey has been conducted to determine the extent to which deceased persons recently received care from hospitals, nursing homes, and sanatoriums during a 1-year period prior to death.

Another survey, the national lung cancer study, using the methodology of the Pennsylvania mortality study, has been extended for a year for cancer deaths in females, but the bulk of information has been collected on smoking habits and residence history. Coding, punching, and tabulating operations are well underway. In the interim one statewide pilot study is in progress to establish the quality of diagnostic information on death certificates for which the coded underlying cause is either malignant neoplasm of the bone or buccal cavity.

Another illustration of society's growing demands on vital records is the task of providing vital records for Americans abroad. This past year, more than 800,000 of our citizens traveled abroad. Each traveler had to prove his birth facts to obtain a passport. These travelers, together with our military personnel stationed in foreign countries, reported nearly 50,000 births to U.S. consular officers throughout the world. Providing satisfactory birth record service for children born abroad who are U.S. citizens is a problem second only to that of obtaining birth certificates for the increasing number of alien children being adopted in the United States. The interagency committee, formed at the request of the Association of State and Territorial Health Officers and the American Association for Vital Records and Public Health Statistics, is making progress toward solution of these problems. At the committee's next meeting, specific concrete recommendations for

new and improved record services for these events should emerge.

These are only a few of the many ways in which the use of vital records can affect man and society. There are many more, from planning for school facilities 5 years hence, when the birth records show there will be a tremendous increase of 6-year-olds in the population, to demands, yet unknown, for planning in the atomic space ages.

Algae in Water Supplies. *PHS Publication No. 657; 1959; by C. Mervin Palmer; 88 pages; \$1.*

This illustrated manual on the identification, significance, and control of algae has been prepared for technicians in water treatment plants and others who deal with algae in water supplies.

Algae are described and shown in color according to their occurrence with taste and odor, filter clogging, pollution, and clean water. Considered separately according to habitat are algae growing on reservoir walls and plankton and other surface water algae. Special attention is given to the beneficial part algae play in sewage treatment as well as the problems they cause. Procedures for enumerating algae are also discussed.

References to related literature are listed at the end of each chapter. The appendix includes a key to algae of importance in water supplies, glossary, bibliography, and genus and species index.

Professional Nurse Traineeship Program.

Part I. A report of the national conference to evaluate two years of training grants for professional nurses. *PHS Publication No. 675; 1959; 62 pages; 30 cents.*

Part II. Facts about the nurse supply and educational needs of nurses based on data compiled for the national conference to evaluate two years of training grants for professional nurses. *PHS Publication No. 676; 1959; 47 pages; 25 cents.*

Part I is the report to the Surgeon General, Public Health Service, by an evaluation conference which met in Washington in August 1958. It presents views and recommendations of nursing, health, and education leaders on how to fulfill the demand for leaders in nursing and an analysis of the Federal Government's first grant program to help professional nurses obtain advanced education in

teaching, administration, and supervision. The appendix includes data on nursing needs as they relate to the program and describes the conference meetings.

Part II is a revision of a source book prepared for orientation and guidance of the conferees. It contains data on nurses who received funds through the program, needs for nurses in top leadership positions, schools where nurses may receive advanced training, and public health agencies, nursing homes, and industries which employ these nurses.

Highlights of Progress in Research on Cancer, 1958. *PHS Publication No. 671; 1959; 46 pages; 25 cents.*

Summaries of selected research findings in virology, pharmacology, epidemiology, and other scientific disciplines reflect significant accomplishments in clinical and laboratory investigation by staff scientists and grantees of the National Cancer Institute, Public Health Service. The items are organized under four broad headings: causation, characteristics, diagnosis, and treatment of cancer.

Fertility Studies Based on Data for the 1960 Census Period. *Vital Statistics—Special Reports; Selected Studies; vol. 47, No. 5; June 8, 1959; pages 145-157.*

Calling for the widest possible participation in and support for studies of fertility, this report considers the kind of fertility studies that might be made from vital and population statistics for 1960 and indicates the ways in which the data should be tabulated in order to make such studies possible. It was prepared by the Subcommittee on Fertility and Population Statistics of the National Committee on Vital and Health Statistics.

Topics suggested for study include concepts of family size; effect on fertility of the dissolution of marriages by divorce or death, and of

remarriage; interrelationships between changes in economic conditions and fertility; birth spacing; and the evaluation of data collected by the National Office of Vital Statistics and the Bureau of the Census.

Interviewing Guides for Specific Disabilities. Pulmonary tuberculosis. *U.S. Department of Labor Publication (unnumbered); revised 1959; 10 pages; 5 cents, \$3.75 per 100.*

Directed to industrial physicians, placement and rehabilitation workers, and employment service staff, this folder outlines the latest information on the treatment, rehabilitation, and employment of tuberculosis patients. It was prepared with the assistance of the National Tuberculosis Association.

The new guide, retaining the established format of the series, is divided into four sections: description of the disability, evaluation of work capacity, definitions, and cooperating agencies.

Sewage and Water Works Construction, 1958. *PHS Publication No. 673; 1959; by William H. Abbott and Elsie M. Gibson; 14 pages; 20 cents.*

Contracts awarded during calendar year 1958 for constructing sewage treatment plants, collecting sewers, and water systems are itemized in this report. Tables present data arranged by States, population groups based on community size, and contract size groups.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D.C.

The Public Health Service does not supply publications other than its own.

Signs

and

Symptoms

of trends in public health

A set of suggested guides for medical care in nursing homes and related facilities has been developed and approved jointly by the American Nursing Home Association and the Council on Medical Service of the American Medical Association. The guides appear in the August 1959 issue of *Chronic Illness*.

“ ”

Jurisdiction over nursing homes was assigned by the Legislature of Ohio to the State department of health, beginning September 7, 1959.

“ ”

Fluoride added to water does not increase corrosion of common household metals, Sanitarian Joseph A. McCarthy reports in *Sanitalks*, quarterly publication of the division of sanitary engineering, Massachusetts Department of Public Health.

In the same issue, preplanning for water supply emergencies is urged by Ralph M. Soule, sanitary engineer. Advance actions suggested by Soule on the basis of Massachusetts experience include having emergency chlorinating equipment and a supply of chlorine compounds on hand, provision for an auxiliary gasoline or diesel engine to drive electrically operated pumping equipment, protection of pumping stations from flooding with polluted waters, and organization and training of auxiliary personnel.

“ ”

A 5-day smog brought death to at least 300 residents of London last December, reported Dr. John Scott, medical officer, County of London. Most died from respiratory disease, including bronchitis.

The new dental clinic of the Philadelphia General Hospital was dedicated on October 14, 1959, equipped with 21 dental chairs, 10 dental units, a dental research laboratory, closed-circuit television, and an intercommunication system. The clinic is completely air conditioned.

Dr. Robert H. Ivy, who in 1901 served at the hospital as the first dental intern in America, was presented with a plaque at the dedication ceremonies.

“ ”

Researchers engaged in the study of cybernetics applied to medicine and biology may now join the recently founded International Society of Cybernetic Medicine, which has offices at 318 Via Roma, Naples, Italy. Physicians, biologists, engineers, physicists, and mathematicians are eligible.

“ ”

Observing that a number of college students, lined up for immunization shots, fainted under the needle, Dr. Joseph Smith, health officer in Providence, R.I., relates that he once marked a circle on the floor and painted instructions in large letters, FAINT HERE. After that, no more students fainted.

“ ”

Forty-nine medical and nursing officers and other specialists are on assignment from the Public Health Service heart disease control program to 27 State and local health departments to help extend and stimulate work in cardiovascular disease control throughout the United States. The total number of these assignments is expected to increase appreciably in 1960.

More men, women, and children are killed by reckless walking than by reckless driving in the District of Columbia, according to a 10-year survey by the American Automobile Association, which established that two-thirds of all deaths from traffic on D.C. streets were pedestrians.

“ ”

Farm labor camp operators in New York State must meet stricter requirements in order to obtain operating permits this year. New provisions added to the State sanitary code have strengthened specific requirements in regard to space, fire hazards, bathing facilities, heating facilities, screening, and maintenance of buildings and grounds. Approximately 40,000 migrants work in the State's 1,100 farm labor camps each year.

“ ”

The first recognized case in Brooklyn of rabies in a bat has been reported by Dr. Morris Greenberg, director of the New York City health department's bureau of preventable diseases. Since 1953 the Public Health Service has received reports of 75 persons bitten by rabid bats; all but three bites occurred when a bat was picked up.

“ ”

Radiation is the most important newly emerging public health factor in the United States today, a nationwide panel of Federal, State, and local public health directors told the American Public Health Association.

Air pollution, aging, chronic disease, mental health, safety, urban and suburban expansion, financial management, staphylococcal infections, and medical and surgical care of the indigent, followed radiation closely in the panel's listing.

A series of surveys is planned by APHA to identify changing trends as a basis for improved planning in public health. A panel of 80 has been established for the survey series which includes 52 State and Territorial health commissioners, 20 directors of city or county health departments, and 8 regional directors of the Public Health Service. Each will be queried periodically on trends in his own jurisdiction.

Industrial Hygiene for the Farm

by Mail Order

CLYDE M. BERRY, Ph.D

WHEN A FARMER tries to unclog the mechanical cornpicker, does he realize the danger of keeping the power on? When he enters the silo, does he know what to do to protect himself against lethal gas? Does he know how to handle safely toxic chemicals used on the farm?

Modern farming meets a growing number of hazards. How can health agencies provide the farm with the industrial hygiene services now used in other occupations?

Up to this point, the large farm population at risk has derived little benefit from the Nation's experience and skills in industrial hygiene, partly because these services have developed along custom-tailored, high-quality lines. We shrink from suggesting to the farmer a "do it yourself" program.

Nevertheless, goods and services must flow from the producer and purveyor to the consumer. A method of extending the consumption of industrial hygiene services through a mail-order technique may merit consideration. An analysis of the problems involved in such an approach indicates that it may be possible for farm application.

In an industrial setting, we in industrial hygiene have believed that only limited delegation of responsibility to nonprofessional people can

be made and a performance level be retained that meets our exacting achievement criteria. Sacred has been the conviction that there is no substitute for knowledge, skill, and experience in setting up a sampling regimen, supervising data compilation, interpreting findings, and recommending controls.

The above are valid arguments. The dollar cost of mistakes can be considerable. Injury to health, proximate and ultimate, is a potential that continually haunts us. Resurveys may need to be made. Modification of engineering controls may be required. These are expensive. The individual responsible for a mistake can lose the support of his employer and be discredited by his confreres. This is sobering to the professionally courageous and frightening to the professionally timid.

Almost all of our efforts are unique. Individual problems are exactly that—and must be so studied and controlled. With such an approach it is entirely understandable that problem solving and routine program commitments represent the major part of established programs. With limited staff it is natural to try to do the most in the least amount of time for the greatest number of people.

This situation provides a logical explanation for finding the best industrial hygiene coverage in the larger plants and in those industries with the most acute hazards. In the larger plant, operations are likely to be more continuous. Job assignments are likely to be more specialized. Presenting the findings of studies to management and getting controls initiated is

Dr. Berry, who is associate director of the Institute of Agricultural Medicine of the State University of Iowa, Iowa City, delivered this paper in substantially the same form at the 1959 meeting of the American Conference of Governmental Industrial Hygienists.

ECHOES from Public Health Reports

THE PATCH TEST IN CONTACT DERMATITIS¹

By LOUIS SCHWARTZ, *Medical Director*, and SAMUEL M. PECK, *Senior Surgeon (R)*,
United States Public Health Service

The patch test was devised by Jadassohn (1) almost 50 years ago for demonstrating the causes of contact dermatitis. In the United States the test was not widely used in industry, nor was its practical value appreciated until attention was called to the prevalence of occupational dermatitis and the chemicals causing it, and to the value of the patch test in differentiating between occupational and other sources of contact dermatitis.

The test was first used as a means of determining the actual causative irritant in cases of contact dermatitis. Since dermatitis has on many occasions been found to be caused by irritant chemicals contained in wearing apparel and cosmetics, manufacturers have taken advantage of the patch test to determine the possible skin-irritating or sensitizing properties of new products before placing them on sale to the public.

Some enthusiasts have even proposed the inclusion of the patch test as part of the pre-employment examination with the idea of weeding out those workers who might develop occupational dermatitis. The fallacy of this proposal lies in the fact that most workers develop occupational dermatitis by contact with a primary irritant or by acquiring an allergy while actually employed. Pre-employment patch testing, therefore, could not weed out those who would become sensitized.

It is now universally accepted that the patch test, if properly performed and interpreted, is a valuable diagnostic procedure. Its value in preventing possible outbreaks of dermatitis from the use of

APRIL 28, 1944, pp. 546-557

Dr. Louis Schwartz and Dr. Samuel M. Peck introduced the "prophetic" patch test for determining whether certain substances will produce contact dermatitis. The test is applicable to new chemicals used in manufacturing as distinct from a previous patch test which had been developed for diagnosing the cause of existing dermatitis.

• Offer reassurance that special problems can be met through mail consultation, telephone, or (under unusual circumstances) by a personal visit from a professional.

• Make provision for services such as alterations, return-for-refund, and trade-in.

• Suggest financing methods, tax credits, amortization rates, and relationships to any legal liabilities which might be involved.

• Keep performance claims conservative. This implies building in an extra margin of safety.

Our problem can be compared roughly to that of merchandising in rural areas soon after the wide expanses of America were opened up to homesteading. Railroads and stagecoaches provided the link between villages and towns. Special needs of consumers were met by making articles on the premises. Where special skills were required, as in blacksmithing and leathercraft, artisans set up shop. For regularly used items that could be mass-produced in the industrial east there was the outlet of the general store. The general store, however, was limited in the stock it could carry as to kind, size, color, material, or other features. The distance between farm and village was considerable and trips were infrequent. A government service to the individual farm or ranch provided an answer. Rural free delivery of mail made the mail-order house possible, and the combination resulted in an effective approach that may have merit in an analogous manner for the current professional dilemma which we face.

We shall need to curb our natural response—that this cannot be adapted to industrial hygiene—and approach it with an open mind. Perhaps it can be applied to industrial hygiene, if we try.

Remember, we are directing our efforts toward the mass markets, not the carriage trade. We seek to capture the industrial hygiene build-it-from-a-kit group. What changes are in order for us to provide mail-order industrial hygiene for the farm? At the risk of losing my membership in our professional societies, I would like to present the following arguments for considering such an approach.

Farmers are not being reached. Until small plant needs have been met farmers will still be

professionally neglected. They have a problem. How can we justify any delay in providing them with a needed service, however meager?

We will do more good than harm. Those instances where untoward results from faulty choice of equipment, improper maintenance, a false sense of security, and other factors will be outweighed by acceptable control procedures.

Under certain circumstances sacrificing quality for quantity can be justified. Why can't we adapt the "weighted exposure" concept to the situation? Wouldn't a little industrial hygiene for a lot of people be as justifiable as intensive service for a few?

The Catalog

Let us assume that the arguments above have been cogent and convincing. How can we make industrial hygiene for the farm by mail order work? The following methodology is offered as the first halting step in this direction.

Concentrate first on a "catalog." Prepare material that will be most amenable to a do-it-yourself approach, for hazards that have the most serious potentials, and for the largest number of farmers.

Get the catalog into the hands of the farmer. Many avenues are available: direct mail; distribution by farm children, rural organizations, or farm extension personnel; over-the-counter from farm equipment outlets or hardware stores; or on a request basis, with the demand built up by blanketing farm communication media—magazines, newspapers, radio, and television.

Concentrate heavily on timing and lucidity. The farmer has seasonal problems. Anticipate these so he can avoid emergencies and inevitable improvisations. The material should be so presented that he can see it applies to him and his operations.

Aim for standardization. "packaged" control. Inevitably this will lead back to the manufacturer, the packager, and to sales and service outlets for farm needs. It is a laudable objective in the area of farm operations. Specifications should take precedence over the traditional faith in brand name with the added information on make and model.

easier if management had been faced with repeated situations of a comparable nature and is "educated" to work with industrial hygiene people.

Providing industrial hygiene services for the small plant is not easy. We swim yearly through a sea of salty tears as we deplore this lack of services and fervently discuss ways and means of providing these needed services. We concede that the plants are widely scattered and travel time is considerable. The few people employed have multiple duties. Other parameters include variations in processing, transient personnel, poor plant maintenance, lack of medical supervision, inadequate housekeeping, hand-to-mouth financing, lack of mechanization, and absence of records.

Providing industrial hygiene services to the farm is a somewhat similar but even more difficult problem. The additional parameters include a most geographically diffuse population at risk; the home and the workplace are the same; management and labor are identical; the worker may be of either sex and will range widely in age, intelligence, education, normal health status, and training for a specific job.

Further complications are that the jobs may be highly intermittent; may be performed indoors or outdoors; and may be heavily influenced by the weather and climate. They are subject to considerable variation in personal hygiene and in the availability and use of personal protective equipment. There is no separate maintenance man or operator. The farmer is both.

How can an industrial hygiene service that will meet the exacting criteria we have established be provided to a one-family operation? I have grave personal misgivings that this can ever be achieved. If we have not been able to meet the needs of the small plant, how can we meet the needs of the farmer? Will there be enough money? Enough people? Can the problems which we described be circumvented?

It seems unlikely that there will be enough money and people to do the kind of job that we have held to be acceptable by our professional standards. Our choice, then, is one of necessity. We can perform individual, high-quality industrial hygiene services and be of little help to the great mass of those who need help. The

alternative is heresy: to sacrifice quality for quantity.

Let us frankly consider how such wide coverage might be provided:

Can a system be devised for enabling the farmer to identify his problem?

If there are unusual aspects to the problem, a nonstandard situation, can it still be identified? Can a farmer describe his problem in nontechnical terms?

Can the system provide for the expert but remote appraisal of nonstandard conditions? Can control suggestions be provided to the farmer in nontechnical terms—not only so he can understand them, but so that he cannot misunderstand them?

If professional heresy can be hypothetically condoned for the moment, then one can speculate further as to how these problems of the farmer can be handled from a distance. Let us suppose that it is possible to place in the hands of the farmer a device for visual association that can assist him in identifying problem areas, real and potential, known and unknown. The device would:

- Apply specifically to individual farm equipment items and operations, or either, that are used or performed by the particular farmer to whom the device is provided.
- Be sufficiently specific so that alternative control approaches are definable by the farmer as to first cost, cost of operation, service factor, and degree of probable effectiveness.
- Provide enough option in listings of size, mounting, power source, and materials of fabrication for a fairly wide range of needs, and discuss farm-use variables such as severity and duration of exposure, weather conditions, and equipment breakdown.
- List sufficient detail for satisfactory ordering, shipping, installing, and testing.
- Indicate in advance what will be involved in maintenance, storage, multiple application, power consumption, and provide a listing of depots where expendable items and repair parts may be secured.
- Emphasize comparison and choice (management prerogatives).
- Minimize coercive overtones.
- Point out profit incentives as far as possible.

Children with rheumatic fever or heart disease are given a wide range of educational services, a national survey discloses. Methods to provide these essential services in all urban areas are recommended.

Educational Services for Urban Children With Rheumatic Fever or Heart Disease

HELEN M. WALLACE, M.D.

CHILDREN with rheumatic fever or heart disease, either rheumatic or congenital in origin, were one of the first groups for whom special educational provisions were made by departments of education. These special educational provisions, over and above regular classes in regular schools, included teaching in special classes, special day schools, special residential schools, hospitals and convalescent homes, and in the child's home. Evidence of a consistent decline in the incidence and prevalence of rheumatic fever and rheumatic heart disease in children and youth is accumulating (1). Because of this obvious trend, it seems timely to look at the special provisions made for children with rheumatic fever or heart disease by public school systems in the larger cities of our country.

Method of Study

During the winter of 1958, a questionnaire was sent to the health officers and superintendents of schools of each of the 106 cities in the United States having a population of 100,000 or more according to the 1950 census. It con-

tained questions regarding the types and numbers of handicapped children cared for in the public school system; age of admission; type of school facilities; presence of established criteria for special educational placement and the agency responsible for their establishment; method of reviewing applications for special educational placement, personnel engaged in such review, and frequency of review; organization of special education within the public school system; method of financing and costs of education of handicapped children; and the provisions made for transportation and attendant service during transportation of handicapped children to and from school.

According to the 1950 census, the 106 cities had a combined total population of 44,311,716, or 29.4 percent of the total U.S. population, and a combined school enrollment of children aged 5 through 17 years of 7,192,100, or 28.4 percent of the total U.S. population. Ninety-eight of the 106 cities, or 92 percent, responded. These 98 respondent cities had a combined total population of 41,686,921, or 94 percent, and a combined school enrollment of children aged 5 through 17 years of 6,849,105, or 95 percent. All but 9 of the 98 respondent urban communities provide some special school services for children who have rheumatic fever or heart disease.

Dr. Wallace is professor of maternal and child health, School of Public Health, University of Minnesota.

If all automatic silo unloaders were reinstalled at the time the silo is filled, a built-in device would be available for eliminating exposure to silo gas. The catalog might give the following instructions for ordering a spiral, wire-reinforced, flexible, cloth duct to fit the fan discharge of a silo unloader:

Diameter. Measure outside diameter between two pieces of wood held parallel to each other as shown in figure 1. This is the inside diameter of the tube. Order next larger size.

Length. Allow for settling of 15 percent of height of silo. Calculate in feet. Add distance (in feet) from center of silo to inside wall. This is the length to be ordered.

Installation. Remove blower chute; place tube over circular fan discharge opening and clamp as shown in figure 2. Attach wall hanger as shown in figure 3. Fasten to wall at window or farthest point from any nearby building.

Operation. Make visual observation from the ground that discharge end of tube is in place. Operate unloader for 15 minutes before entering silo.

Warn: To avoid removing sludge, support unloader above sludge as shown in figure 4. The support should be 4-6 inches thick and approximately 24 inches in diameter.

Summary

Justification has been attempted for departing from high-quality, custom-type industrial hygiene services in order to serve a geographically diffuse population at risk. The method proposed for such a group involves many of the techniques of merchandising by mail. General suggestions for applying such a service to agricultural operations are made.

Observance Date for Child Health Day Changed

Child Health Day will be observed on the first Monday in October beginning with 1960, instead of on the traditional May 1. The change, effected through joint congressional resolution, permits the United States to link observance of that day with Universal Children's Day, which many nations observe on the October date.

Since 1956, by agreement between the United States and the United Nations, the Child Health Day proclamation has contained references to Universal Children's Day and to the work of the United Nations and the United Nations Children's Fund.

Child Health Day has been observed on May 1 every year since 1928. Since 1935, the Children's Bureau, as requested by the Association of State and Territorial Health

Officers, has sponsored appropriate Federal activities.

States and communities frequently use the day to call attention to a particular condition affecting children or to enlist community support in improving the health of children. For example, the day was once used to initiate a campaign for immunization against diphtheria and smallpox. It has also been used to emphasize the values of birth registration, community planning, prevention of home accidents, and medical and dental examinations for children entering school for the first time.

The theme of "Child Health" in 1960 is expected to reflect the significant findings of the 1960 White House Conference on Children and Youth.

Children with rheumatic fever or heart disease are given a wide range of educational services, a national survey discloses. Methods to provide these essential services in all urban areas are recommended.

Educational Services for Urban Children With Rheumatic Fever or Heart Disease

HELEN M. WALLACE, M.D.

CHILDREN with rheumatic fever or heart disease, either rheumatic or congenital in origin, were one of the first groups for whom special educational provisions were made by departments of education. These special educational provisions, over and above regular classes in regular schools, included teaching in special classes, special day schools, special residential schools, hospitals and convalescent homes, and in the child's home. Evidence of a consistent decline in the incidence and prevalence of rheumatic fever and rheumatic heart disease in children and youth is accumulating (1). Because of this obvious trend, it seems timely to look at the special provisions made for children with rheumatic fever or heart disease by public school systems in the larger cities of our country.

Method of Study

During the winter of 1958, a questionnaire was sent to the health officers and superintendents of schools of each of the 106 cities in the United States having a population of 100,000 or more according to the 1950 census. It con-

tained questions regarding the types and numbers of handicapped children cared for in the public school system; age of admission; type of school facilities; presence of established criteria for special educational placement and the agency responsible for their establishment; method of reviewing applications for special educational placement, personnel engaged in such review, and frequency of review; organization of special education within the public school system; method of financing and costs of education of handicapped children; and the provisions made for transportation and attendant service during transportation of handicapped children to and from school.

According to the 1950 census, the 106 cities had a combined total population of 44,311,716, or 29.4 percent of the total U.S. population, and a combined school enrollment of children aged 5 through 17 years of 7,192,100, or 28.4 percent of the total U.S. population. Ninety-eight of the 106 cities, or 92 percent, responded. These 98 respondent cities had a combined total population of 41,686,921, or 94 percent, and a combined school enrollment of children aged 5 through 17 years of 6,849,105, or 95 percent. All but 9 of the 98 respondent urban communities provide some special school services for children who have rheumatic fever or heart disease.

Dr. Wallace is professor of maternal and child health, School of Public Health, University of Minnesota.

Previous papers reported on the general information obtained from the questionnaires regarding all types of handicapped children and children with orthopedic, neuromuscular, or neurological conditions (2,3).

This paper summarizes the information obtained regarding children with rheumatic fever or heart disease.

Educational Placement Available

The most common types of educational placement for children with rheumatic fever or heart disease, other than regular class in a regular school, are home instruction, special day class, combination of home instruction and special day class, and special day school (table 1).

It is of some interest that 45 communities provide placement by home instruction, 29 in a special day class, 22 in classes in a hospital or convalescent home, 17 in a special day school, and 1 in a special residential school.

Table 1. Public school educational placement, by type other than regular classes in regular schools, of children with rheumatic fever or heart disease

Type of placement	Number of school systems
Home instruction only	19
Special day class only	8
Special day class and home instruction	6
Special day school only	6
Special day class, home instruction, hospital or convalescent home	5
Special day school, home instruction, hospital or convalescent home	5
Special day class, special day school, home instruction, hospital or convalescent home	3
Special day class, special residential school, home instruction	3
Home instruction, hospital or convalescent home	3
Hospital or convalescent home only	3
Special day class, hospital or convalescent home	1
Special day class, special day school	1
Special day class, special day school, hospital or convalescent home	1
Special day class, home instruction, special residential school	1
Special day school, hospital or convalescent home	1
Uncared for or not reported	32
Total	98

Table 2. Number of children with rheumatic fever or heart disease reported by school systems

Type of placement	Number of children	Number of school systems	
		Providing service	Reporting number of children
Regular class	1,065	98	11
Home instruction	755	15	41
Special day school	593	17	17
Special day class	181	29	24
Hospital or convalescent home	210	22	19
Special residential school	67	1	2

Some communities provide just one type of special placement: 19 by home instruction, 8 in a special day class, 6 in a special day school, and 3 in a hospital or convalescent home.

Officials were asked to report the number of known children with rheumatic fever or heart disease in the various types of educational placement. This question was incompletely answered on the questionnaires. There was more complete reporting of the number of children in hospital and convalescent homes, special day classes, special day schools, and receiving home instruction than of children in regular classes or in special residential schools. The largest single group of children reported was in regular classes, followed by home instruction, special day schools, and special day classes in that order. Only a few children were reported to be in special residential schools. Undoubtedly there was considerable under-reporting of children in regular classes (table 2).

Educational Placement Method

Ninety-one of the ninety-eight reporting public school systems, or 93 percent, stated that they had established criteria for the educational placement of all types of handicapped children. One each had established criteria only for cerebral palsy, for the blind, and for mental retardation. Four did not answer this question.

In almost one-half of the public school systems, responsibility for establishing criteria for

educational placement has been assumed by the local government, predominantly the local board of education. In slightly more than one-quarter, the responsibility has been assumed by the State government, predominantly the State department of education. The participation of the health department, either local or State, is very small. When the individual disciplines are listed under local government, there is medical participation in less than one-half of the methods.

In one-half of the public school systems, the board of education alone reviews applications for special educational placement. In no instance is such review done by the department of health alone. In approximately one-fifth of the school systems the review is carried on jointly by the departments of education and health. In only three school systems was the recommendation of the practicing physician acted upon without any agency review.

The number of professional personnel reviewing applications for educational placement ranged from 1 in one school system to 12 in another. The most frequent number of participants was 6 in 18 school systems. In all but two of the school systems, more than one professional person is responsible for the review of applications.

The type of professional person participat-

ing in the review of applications is of the utmost importance. - The psychologist and the school administrator participate most frequently, 87 school systems reporting the use of these professions. The nurse and the teacher participate as reviewers in about one-half of the school systems, the social worker and the school counselor in about one-third. There is limited participation by such personnel as the director of special education and the vocational counselor.

In all school systems except 14, there was some type of medical participation in review of applications. It is surprising to find infrequent participation by certain medical specialists, especially the cardiologist and the pediatrician.

It is considered essential that there be a careful review of all handicapped children, not only prior to educational placement but also periodically during such placement and prior to withdrawal from such placement. The questionnaire asked for information on all three aspects. Ninety-six percent of the school systems indicated that they review all applications prior to placement, 85 percent do so periodically during placement, and 70 percent prior to withdrawal from placement. Inquiry was also made regarding the frequency of periodic review of the children during placement. At

Table 3. Frequency of review of all types of handicapped children during placement

Frequency of review	Regular class	Special day classes	Special day school	Special residential school	Home instruction	Hospital or convalescent home
Once a week.....				1	1	
Once a month.....				1	2	
Once every 6 weeks.....					1

least once a year, 45 percent of the school systems review children in special day classes, 39 percent review children on home instruction, 32 percent review children in regular class, 31 percent review children in special day school, 17 percent review children in special hospitals and convalescent homes, and 9 percent review children in special residential schools. The stated range of frequency of review varied from once a week (in one special residential school and on home instruction) to a complete lack of review for children on home instruction in two school systems (table 3).

Because it is recognized that "paper review" of children may not provide as complete a picture of the child, his progress, and his needs as a personal visit with the child and his family, the questionnaire asked if a team of personnel, either from the board of education or the department of health, sees and evaluates all handicapped children personally. Thirty-eight percent of the communities provide such a team, 35 percent do not, and 27 percent did not answer this question. The number of persons employed on a team basis for evaluation of the rheumatic fever or cardiac group vary from one person in about 10 percent of the communities to six persons in two communities. The majority of the communities provide a team of from one to three people as shown below.

<i>Number of personnel</i>	<i>Number of school systems</i>
One	9
Two	12
Three	8
Four	0
Five	1
Six	2
Team	1
Clinic	4

A psychologist and a physician (whose type was not stated) were most frequently on a team. Other personnel used with some degree of frequency were the teacher and the nurse. Community facilities were used rarely, and personnel such as social workers, school counselors, school physicians, and certain medical specialists (pediatrician and cardiologist) were used relatively infrequently. Another surprising finding was that a crippled children's clinic was reported as being used in only

two instances. In three communities, there was team evaluation of children with rheumatic fever or heart disease without any medical participation on the team. The type of personnel engaged in team review and the number of school systems reporting are shown below. Replies were received from 37 cities, 28 indicating that more than one person is used for evaluation.

<i>Type of personnel</i>	<i>Number of school systems</i>
Psychologist	11
Teacher	7
Administrator	5

Crippled children's clinic	2
Clinic physician	1
Consulting clinic	1
Diagnostic team	1

In approximately two-thirds of the public school systems, there is a department of special education with its own director. In approximately one-fifth of the public school systems, special education is a part of another department of the school system.

Of the 98 communities reporting, 50, or 51.1 percent, provide children with rheumatic fever or heart disease transportation to and from school, and 48, or 48.9 percent, do not. Sixteen communities provide attendant service during transportation, or 16.3 percent of the school systems reporting and 32 percent of the school systems providing transportation. In other words, 83.7 percent of the school systems reporting do not provide attendant service during transportation for this group of children, and 68.0 percent of school systems providing transpor-

tation for these children do not also provide attendant service.

Discussion

The foregoing data may be summarized as follows:

- All but 9 percent of the urban public school systems provide some school services for children who have rheumatic fever or heart disease.

- Educational placement of children with rheumatic fever or heart disease, other than regular class in regular school, is most frequently home instruction or special day class, or a combination of these.

- About one-half of the school systems provide placement by home instruction, one-quarter in a special day class, one-fifth in a hospital or convalescent home.

- Thirty-six communities, or 36 percent, provide just one type of educational placement.

- Most of the children are in regular class, with smaller numbers in home instruction, special day school, or special day class.

- In one-half of the communities, criteria for special educational placement have been established by the local board of education, with little participation of the local or State health department.

- In one-half of the communities, all applications for educational placement are reviewed separately by the board of education, and in one-fifth, this review is maintained jointly by the board of education and the department of health.

- In most school systems, applications for special educational placement are reviewed by more than one person, the most frequent disciplines being psychology and school administration. Although there is usually some medical participation, it is rarely a pediatrician or cardiologist.

- Most children are reviewed prior to placement, 85 percent are reviewed periodically during placement (although the frequency varies considerably), and 70 percent are reviewed prior to withdrawal from placement.

- About one-third of the communities provide for team evaluation of children with rheumatic fever or heart disease. The team is usually composed of one to three people, most fre-

quently a psychologist and a physician; infrequently, a cardiologist.

- One-half of the communities transport this group of children to school and one-third of the communities which supply transportation also give attendant service.

Thus the quantitative information indicates that there is less variety of special educational services for children with rheumatic fever or heart disease in most urban communities than for children who are orthopedically handicapped (3), and therefore less flexibility for them. But what of the qualitative information?

A study of 74 eighth grade children in special cardiac classes in one community in 1951 (4,5) indicated that 3 (4 percent) had no heart disease; 21 (28 percent) had possible and potential heart disease (patients in whom the symptoms or signs, though suggestive of heart disease, did not justify a definite diagnosis and from whom a history of an etiological factor which might cause heart disease was obtained); and 50 children (68 percent) had organic heart disease. Of the 50 children with organic heart disease, 37 had rheumatic and 13 had congenital heart disease. Two required no limitation of physical activity, and 39 were permitted to engage in all physical activities except violent competitive sports. Thus, 41 children with organic heart disease, 3 non-cardiacs, and 21 with possible and potential heart disease (a total of 87.9 percent) probably did not require placement in special classes on the basis of medical criteria. Of the remaining nine children with organic heart disease, significant restriction was indicated. Included in the nine were two children with tetralogy of Fallot, one with interventricular septal defect, three with rheumatic heart disease with marked cardiac enlargement, and three with organic disease who had active rheumatic fever less than 1 year prior to the examination.

A subsequent smaller study conducted in 1952 by the New York City Department of Health on all 19 children in two cardiac classes in an elementary school found 6 children (32 percent) were over-restricted, 1 was restricted insufficiently, and 12 children (63 percent) were appropriately placed. Of the 19 children, 13 had

rheumatic heart disease, 5 had congenital heart disease, and 1 had no heart disease.

An evaluation of 10 homebound cardiac children by a team composed of a pediatric cardiologist, a public health nurse, and a medical social worker found 6 children with heart disease (4 severe, 2 mild), 3 children with potential heart disease (history of rheumatic fever but no heart disease), and 1 child, a non-cardiac (6). Of the 10 children, 3 had rheumatic fever, 1 had congenital heart disease, 5 had rheumatic heart disease, and 1 was non-cardiac. Eight of the ten families visited needed public health nursing service, interpretation of illness, anticipation of developmental and emotional problems, and specific dietary and postural advice. Seven of the ten families needed casework service because of the length of time the children were homebound rather than the fact of the illness itself. Most families expressed an additional need for planned recreational programs for the cardiac homebound who is not confined to bed. There was also a need for vocational assistance among the adolescent children.

There is evidence to indicate that in some instances there may be erroneous information regarding the child's diagnosis; there may be inappropriate placement of the child, mostly in the direction of overplacement; and there may be over-restriction of a child's activities.

Recommendations

On the basis of these findings, certain specific recommendations may be made:

1. That each urban community have a range of special educational services for school children with rheumatic fever or heart disease, including special day class, home instruction, and teaching in a hospital or convalescent home.

2. That the local board of education and department of health jointly, with the assistance of professional experts from the various disciplines concerned (pediatrics, cardiology, education, public health nursing, social work, and vocational counseling), establish criteria for the special educational placement of these children.

3. That all applications for the placement of these children be reviewed by a team composed

of the various disciplines listed in the second recommendation prior to placement, periodically during placement (preferably every 3 months), and prior to withdrawal from special placement. Furthermore, it is recommended that children who are in regular classes and have had rheumatic fever or have heart disease be followed carefully. Whenever there is any question, the team should see the child and his family personally rather than rely upon "paper" information only.

4. Because of the need, children with rheumatic fever or heart disease who receive home instruction or are in a special day class or school should be considered a high priority group for public health nursing service.

5. Because of the difficulties of diagnosis, each large urban area should have at least one diagnostic and consultation service for children with rheumatic fever or heart disease to which practicing physicians, school health services, and well child conferences may refer these children for a diagnostic workup. This service might be provided by the local health department, the official crippled children's agency, a local hospital, or the school health service itself.

6. Because of the well-known value of prophylaxis against recurrences of rheumatic fever, it is recommended that school health service personnel periodically (preferably every 3 months) review the current status of each child with a verified history of rheumatic fever. When such a child is not on prophylaxis, school health service personnel should discuss this procedure both with the child's physician and the family.

7. Because of the rapid advances in diagnostic and surgical techniques any child who gives evidence of congenital heart disease and who has not been given an adequate diagnostic workup should be referred for this service.

8. Placement of children in other than regular classes in regular schools should be made only after it is clear that the child cannot possibly fit into this normal setting.

9. Recorded data with adequate information on the continuity of care from the treatment agent or agency is essential, if there is to be a clear picture of the child's course.

10. Wherever possible, the educational setting should be modified to fit the child rather than attempting to place the child in a setting which may be inappropriate.

Summary

Data on children with rheumatic fever or heart disease are extracted from findings of a national survey conducted in 1958 to ascertain the status of school services for all handicapped children in cities having a population of 100,000 or more. Wide variation exists in the range of services, policies, and personnel concerned. Recommendations are made to assure these children the benefit of essential services in all urban areas.

The Yearbook of Agriculture, 1959

In the publication, "Food—Yearbook of Agriculture 1959," the U.S. Department of Agriculture presents 66 articles which represent a comprehensive range of approaches to the subject of food. Contributed by authorities in their respective fields, the articles are grouped under headings such as "The Nutrients," "Health," "Quality," "Preparation," "Costs," and "Trends."

For men, the editor, Alfred Stefferud, recommends articles such as "Nutritional Needs After 25," "What Your Food Money Buys," and "Feeding 6,280 Million." Titles of special interest to parents and teachers include "The Story of Nutrition," "A Table of Food Values," and "Habits—and More." Farmers are directed to "Quality in Animal Products," "Marketing, Quality, and Cost," and "Conserving Nutritive Values."

Also featured are "Adolescents and Young Adults," "Youth Learn About Food," and "Trends in Heights and Weights."

There are 736 pages, liberally illustrated with drawings, charts, and graphs, in the yearbook, the latest in the series of annual volumes that have been printed for 110 years.

Nutrition studies with human beings supplement research with laboratory animals. This group of young women and other such groups serve as volunteer squads to help nutrition researchers find out more about the relation of food to health. Under careful supervision the diet squad follows a rigidly controlled diet for many weeks. A variety of detailed analyses show how the body uses certain nutrients, whether the diet supplies enough of each, and how the nutrients depend upon each other in metabolism. Such studies of men and women of different ages are being carried out in laboratories throughout the country.

American Nurse in Moscow

"Are American policemen trained to deliver babies on the streets because American mothers can't afford to pay for the doctor?"

"Isn't it true that in America if a person has an acute attack of appendicitis and doesn't have the money on him to pay beforehand for the operation, he just has to die?"

"Why is it that in America if a worker has an industrial accident he is thrown out of the plant for good?"

Mrs. Rose G. Ernsberger, a Russian-speaking nurse officer of the Public Health Service, spent her summer answering these and similar questions on American public health practices at the American National Exhibition in Moscow. The exhibition enjoyed a daily attendance of some 60,000 Russians, of whom hundreds flocked to the public health exhibit to see and hear about medicine in the United States.

From 11 a.m. to 9:30 p.m. 7 days a week, Mrs. Ernsberger was subjected to a bewildering array of questions about American treatment of cancer, heart disease, hypertension, bronchial asthma, tuberculosis, stomach ulcers, and almost every other illness.

Each day, as soon as she stepped up to her lecture stand under the exhibition's geodesic dome and plugged in her microphone, a crowd gathered. "At first they were rather shy and stayed back from the platform as if they didn't know what to say. Then someone would gather his courage, rush up to the stand, and demand to know 'how do you treat such-and-such?' This signal would break the ice, and others would crowd around," according to the nurse.

"They wanted to know if we permit abortions, how we cure sterility, and what sort of aid we give to expectant mothers. The last question is especially important to Soviet workers, because mothers there have to work in

order to bring the family income up to some reasonable level. It was quite a revelation to them to hear from me that, although we do have annual sick leave, pregnancy allowances, and other benefits, we don't have any well-defined national system for pregnancy care because we Americans generally feel that mothers should stay home and take care of their children.

"Another question concerned day nurseries. Working mothers in the Soviet Union leave their children in such nurseries, which are common throughout the country. They wanted to know why we do not have many such nurseries. The answer was that our mothers take care of their own children. They seemed to understand that."

The Russians have been taught to believe that there is no free medical care in the United States and that good medical care in general is too expensive for the average working family to afford. Mrs. Ernsberger told them: "There are 26 million families in the United States with hospitalization insurance. Free medical care is given by Government hospitals, private clinics, and a variety of other public and private institutions. The decision whether a patient pays or not is made by public health nurses and social workers. Anybody in the United States can get medical care, whether he can pay for it or not."

Most of the Russian visitors to the exhibition believed the answers, but almost every group around her contained one or two hecklers. If they loudly expressed doubt, Mrs. Ernsberger would say, "I've been a nurse in America for 30 years and a public health nurse for 18. If you don't believe me, this doesn't hurt us Americans at all, because we still get the same splendid services. I know, because I live there."

National Hospital Insurance in Canada

FRANCIS d'A. COLLINGS, M.A.

JULY 1, 1959, marked the first anniversary of national hospital insurance in Canada. It is too early yet to evaluate the new Canadian program in terms of experience, since only half of the 10 Provinces have participated for the full year, and data on costs, utilization, and other matters of interest are not yet available. It is an appropriate time, however, to survey some structural details of the new program. With respect to the financing of hospital care, as in many other areas, Canada has evolved what is essentially a middle way between American and British practice. The hospital insurance system now emerging in Canada is sufficiently different from our own—and in a general social, economic, and political setting sufficiently similar—to merit close interest in the United States.

The background of the Canadian hospital insurance program and the history of events that led up to it have been adequately described elsewhere (1,2). This report will sketch briefly the outlines of the national program, and then describe in greater detail some aspects which may be of particular interest to those concerned with health and medical care planning in this country. The report is based partly on published material, partly on conversations with officials of the Department of National Health and Welfare in Ottawa and other persons in the Canadian health field.

The Federal Act

The Hospital Insurance and Diagnostic Services Act, authorizing "contributions by Canada in respect of programmes administered by the Provinces providing hospital insurance and laboratory and other services in aid of

diagnosis" (3), was enacted by unanimous vote of the Canadian Parliament more than 2 years ago. Its effectuation was delayed by a requirement that a majority of the 10 Provinces, having among them at least 50 percent of Canada's total population, be ready to participate. This requirement was eventually deleted, and the program commenced on July 1, 1958. The deletion was made in order to get the program started without waiting for Ontario. This province, with almost one-third of Canada's population, was by then fully committed, although its plan was not due to start until January 1959.

The act provides for a Federal contribution of approximately 50 percent of the costs of Provincial hospital insurance plans. The plans must provide certain benefits and meet certain conditions laid down in the act, but otherwise are entirely Provincial responsibilities. Details of participating plans are drawn up in written contractual agreements between Federal and Provincial governments, an arrangement constitutionally in accord with the British North American Act of 1867 (Canada's written constitution), which makes health and welfare specifically a Provincial responsibility.

Inpatient hospital benefits that must be provided by participating Provincial plans include:

- Ward-level accommodation and meals for as long as the physician considers them medically necessary.
- Necessary nursing services.

At the time this paper was written, Mr. Collings was an economist in the Division of Public Health Methods, Public Health Service. He is presently with the International Monetary Fund.

- Diagnostic procedures together with necessary interpretations, including laboratory and radiological tests (but excluding clinical procedures related to diagnosis, which are considered medical rather than hospital services).

- Operating room, case room, anesthetic facilities, and such items as routine surgical supplies.

- Drugs, biologicals, and related preparations used in the hospital, as prescribed by the physician.

- Radiotherapy and physiotherapy where available.

- Services of salaried hospital personnel, excluding physicians giving medical and surgical care to individual patients, but including services provided by interns, residents, medical administrators, physiotherapists, radiotherapy technicians, occupational therapists, and social workers employed by the hospital.

Optional services which the Province may include as part of its hospital plan are:

- Rehabilitation and cancer programs.

- All or some of the above inpatient services on an outpatient basis.

An important condition for Provincial participation is that all these benefits, required or optional, must be available to all residents of the Province upon "uniform terms and conditions" (3), without restrictions, for example, as to age or income. This does not necessarily mean that coverage must be compulsory for all residents, although in fact most Provinces have chosen to make it so. Residency in the Province is defined to apply to everyone who makes a home there, including U.S. citizens, "new Canadians" (new immigrants), and other foreign citizens. Tourists and transients are excluded.

It must be stressed that these benefits cover only basic hospital care, and do not cover medical and surgical services provided in hospitals by physicians (including anesthetists), except insofar as provided by salaried hospital personnel, as mentioned earlier. If the patient wants accommodation above that provided at the basic level, for example, a private room, he must pay the extra cost. Mental and tuberculosis hospitals do not come under the program, nor do nursing homes, although patients in these institutions are eligible for transfer

to general hospitals for insured hospital care if deemed medically necessary.

The Federal Contribution

The act, as well as specifying minimum requirements of participating Provincial plans, sets out the formula which determines the Federal share of the cost of the Provincial plan. This formula is related to hospital costs in the Provinces rather than to fiscal capacity or need.

The Federal contribution to the cost of each Provincial plan is 25 percent of the per capita cost of inpatient services in the Province plus 25 percent of the per capita cost of inpatient services in Canada as a whole, multiplied in each case by the average number of insured persons. The Federal contribution to all Provincial plans is thus approximately 50 percent of cost, although for individual Provinces it will vary from about 45 percent in high-cost Provinces such as Ontario to about 72 percent in low-cost Provinces such as Newfoundland. The costs of outpatient services, where provided, are shared in the same proportion as those of inpatient services. Monthly advances are made to the Provinces pending final calculation of these figures at the year's end.

To give an example of how this grant formula works, the average per capita cost of inpatient services for Newfoundland in 1959 is currently estimated by the Department of National Health and Welfare at \$17.17, and for Canada at \$24.84. (Details of how these figures are computed will be examined later.) Newfoundland then receives 25 percent of its per capita cost, or \$4.29, plus 25 percent of Canadian per capita cost, or \$6.21, making a Federal contribution to Newfoundland for inpatient services of \$10.50 per person. Ontario, whose per capita cost is estimated at \$26.60, would receive \$6.65 plus \$6.21, totaling \$12.86—a larger absolute amount per capita, but a smaller proportion of total cost per capita.

Since the Provinces with the lowest per capita hospital costs are also the poorest, this formula does tend in fact to give greatest assistance to those with the lowest fiscal capacity. The formula is designed, however, to exert an equalizing influence on hospital standards

Note on Federal Aid to Health Programs in Canada

While Canada, particularly in the postwar years, has placed growing emphasis on unconditional fiscal aid to the Provincial governments, the conditional grant programs have not been neglected. They have covered a wide range with heavy emphasis on health and welfare.

The relative importance of conditional and unconditional grants has been sharply altered, however, with the coming into effect of hospital insurance in July 1958. With only six Provinces participating in the first year, the Federal cost in fiscal year 1959 should not exceed \$70 million. With all Provinces in, the cost will rise to about \$200 million. Total conditional grant payments have not much exceeded \$100 million in any year since the old age security payments became a sole Dominion responsibility in 1952.

In all its conditional grant programs, Canada has resisted the arguments in favor of fiscal need differentials in the scale of payments to the various Provinces. This was not because the Provinces do not differ widely in their relative wealth. They do, indeed. Personal income per person varies from \$768 in Prince Edward Island to \$1,676 in Ontario, with a national average of \$1,395. Rather, it was because in recent years these programs had developed alongside the general unconditional fiscal aid arrangements, which, it was felt, made a fiscal aid factor in the conditional grant programs superfluous.

This unconditional assistance has increased substantially from year to year, but nevertheless it could be said with good reason that these special programs laid a heavier proportionate burden on the revenues of the poorer Provinces, sometimes with budgetary side effects in the relative emphasis accorded different services.

The problem was further complicated with the hospital insurance program by its very size, which

made the relationship to the scale of unconditional aid rather tenuous, and by the fact that standards of facilities and services differed widely from Province to Province. These widely different standards were not considered in keeping with a truly national scheme, and some additional incentive to improvement was required. Further, it was realized the scheme would never get off the ground in the poorer areas without a special stimulus. The situation was modified substantially by the expectation, based on experience, that costs would tend to even out as facilities were developed. Any large cost differential was considered likely to be of fairly limited duration.

The method devised to meet the situation was unique, at least in Canada's experience. The Federal share was to be 50 percent of the accepted cost. To meet the special regional problems it was decided to pay each Province 25 percent of the average per capita cost of hospital services in Canada as a whole plus 25 percent of the average per capita cost in each Province, multiplied by that portion of the Provincial population eligible under the particular scheme.

Thus, although the Federal cost is 50 percent for Canada as a whole, it is more than 70 percent in the poorest Province with lowest costs and between 45 and 50 percent in wealthier areas with well-developed services.

The contribution of this distribution to the fiscal well-being of the Provinces is secondary. The real test will be whether it is successful in raising standards of care in the less-favored Provinces of the federation, as would seem proper in a scheme that it essentially national.—R. M. BURNS, *Director, Federal-Provincial Relations Division, Department of Finance, Ottawa.*

rather than to equalize hospital costs as such. A poor Province such as Newfoundland, which now has nearly three-quarters of the cost of its plan paid by the Federal Treasury in Ottawa, will be enabled to raise salaries and improve standards in its hospitals. As it does so, the per capita cost of hospital service under the Provincial plan will rise and the proportionate

contribution of the Federal Government will fall.

There are no limits on the size of the Federal contribution. This exerts economic pressure upon the Provinces to increase the scope of their hospital plans by including services optional under the Federal act, such as outpatient service and rehabilitation programs.

- Diagnostic procedures together with necessary interpretations, including laboratory and radiological tests (but excluding clinical procedures related to diagnosis, which are considered medical rather than hospital services).

- Operating room, case room, anesthetic facilities, and such items as routine surgical supplies.

- Drugs, biologicals, and related preparations used in the hospital, as prescribed by the physician.

- Radiotherapy and physiotherapy where available.

- Services of salaried hospital personnel, excluding physicians giving medical and surgical care to individual patients, but including services provided by interns, residents, medical administrators, physiotherapists, radiotherapy technicians, occupational therapists, and social workers employed by the hospital.

Optional services which the Province may include as part of its hospital plan are:

- Rehabilitation and cancer programs.

- All or some of the above inpatient services on an outpatient basis.

An important condition for Provincial participation is that all these benefits, required or optional, must be available to all residents of the Province upon "uniform terms and conditions" (3), without restrictions, for example, as to age or income. This does not necessarily mean that coverage must be compulsory for all residents, although in fact most Provinces have chosen to make it so. Residency in the Province is defined to apply to everyone who makes a home there, including U.S. citizens, "new Canadians" (new immigrants), and other foreign citizens. Tourists and transients are excluded.

It must be stressed that these benefits cover only basic hospital care, and do not cover medical and surgical services provided in hospitals by physicians (including anesthetists), except insofar as provided by salaried hospital personnel, as mentioned earlier. If the patient wants accommodation above that provided at the basic level, for example, a private room, he must pay the extra cost. Mental and tuberculosis hospitals do not come under the program, nor do nursing homes, although patients in these institutions are eligible for transfer

to general hospitals for insured hospital care if deemed medically necessary.

The Federal Contribution

The act, as well as specifying minimum requirements of participating Provincial plans, sets out the formula which determines the Federal share of the cost of the Provincial plan. This formula is related to hospital costs in the Provinces rather than to fiscal capacity or need.

The Federal contribution to the cost of each Provincial plan is 25 percent of the per capita cost of inpatient services in the Province plus 25 percent of the per capita cost of inpatient services in Canada as a whole, multiplied in each case by the average number of insured persons. The Federal contribution to all Provincial plans is thus approximately 50 percent of cost, although for individual Provinces it will vary from about 45 percent in high-cost Provinces such as Ontario to about 72 percent in low-cost Provinces such as Newfoundland. The costs of outpatient services, where provided, are shared in the same proportion as those of inpatient services. Monthly advances are made to the Provinces pending final calculation of these figures at the year's end.

To give an example of how this grant formula works, the average per capita cost of inpatient services for Newfoundland in 1959 is currently estimated by the Department of National Health and Welfare at \$17.17, and for Canada at \$24.84. (Details of how these figures are computed will be examined later.) Newfoundland then receives 25 percent of its per capita cost, or \$4.29, plus 25 percent of Canadian per capita cost, or \$6.21, making a Federal contribution to Newfoundland for inpatient services of \$10.50 per person. Ontario, whose per capita cost is estimated at \$26.60, would receive \$6.65 plus \$6.21, totaling \$12.86—a larger absolute amount per capita, but a smaller proportion of total cost per capita.

Since the Provinces with the lowest per capita hospital costs are also the poorest, this formula does tend in fact to give greatest assistance to those with the lowest fiscal capacity. The formula is designed, however, to exert an equalizing influence on hospital standards

The Federal act and the written agreements with the Provincial governments setting up the framework of the national hospital insurance program in Canada allow considerable individuality in Provincial plans.

Differences in Provincial Plans

The method of financing the Provincial share of the cost of the plan is one point of difference. Four of the eight Provinces with plans now in operation (Ontario, Manitoba, Saskatchewan, and New Brunswick) have chosen to levy premiums on the insured population. Annual rates are \$25.20 for single persons and \$50.40 for families in Ontario, \$24.60 and \$49.20 in Manitoba, \$17.50 and \$35 in Saskatchewan, and \$24.60 and \$49.20 in New Brunswick (5). The other Provinces finance their share from general revenue or special sales taxes.

On the issue of compulsory versus voluntary coverage, clearly only "premium Provinces" can allow residents a choice of whether to contribute or not. The Ontario plan makes coverage compulsory for employees working in establishments of more than 15 persons, but for others it is optional, with voluntary registration and payment of premium. This arrangement was adopted not out of deference to the principle of voluntarism, but rather because of the difficulty in collecting compulsory contributions among small groups and the self-employed. Alternatives to the Provincial plan in the form of nonprofit or commercial insurance for basic hospitalization are now forbidden, so the effective choice for Ontarians is Provincial hospital insurance or no hospital insurance. Ninety-three percent of the population of Ontario is now in fact covered by the Provincial plan. New Brunswick and Prince Edward Island have adopted similar arrangements, but in all other participating Provinces coverage is in effect compulsory for all residents.

Deterrent charges, or "hesitation fees," have been adopted by two Provinces of the eight. British Columbia, whose plan dates from 1949, continues to charge \$1 per day for hospitalization. Alberta levies a variable charge of from \$1.50 to \$2.00 per day depending upon the size of hospital, and a flat \$1 per day (up to a maximum of \$30) for newborns. These charges

are expected to meet only a small part of total cost—about 6 percent in British Columbia and 12 percent in Alberta (4)—and their main intent is to control utilization.

Each Province must provide at least the inpatient services specified in the act. Most of them, for the present, limit services insured under the Provincial plan to this level, but there is nothing to prevent a Province from providing a wider range of services if it wants to pay for them itself. Thus, Ontario and in effect Saskatchewan as well have chosen to include care in mental and tuberculosis hospitals as part of insured benefits, the additional costs being met entirely from Provincial revenues. Whether as a part of insured hospital benefits or under other public programs, the Provinces of Canada, like the States in the United States, subsidize care in tuberculosis and mental hospitals.

Insured outpatient services, optional to the Provinces, vary across the country. Newfoundland, for example, provides outpatient laboratory and radiological services, encephalograms, cardiograms, and basal metabolism estimates, all together with necessary interpretations, radiotherapy and physiotherapy treatment for ambulatory patients, and other outpatient care provided by salaried hospital staff. At the opposite end of the scale, Alberta provides no outpatient services at all. All other participating Provinces include at least emergency outpatient service within 24 hours of an accident (48 hours in Nova Scotia). The small range of outpatient benefits in several Provinces is regarded as temporary, to be liberalized as the plan gets underway. Manitoba has already (in February 1959) extended its coverage of outpatient benefits in the interest of reducing pressure on inpatient facilities, and others may follow suit shortly.

Limitations on drugs that may be prescribed as part of insured hospital service also vary. Most Provinces have left the matter to be decided according to accepted medical practice, with some provision for medical review. Saskatchewan and British Columbia, possibly through longer experience, have listed certain exclusions. Saskatchewan, for example, excludes amino acids, injected antibiotics other than penicillin, and streptomycin; and British

As far as the Provincial authority is concerned, these services may be added to the plan at half cost, since the other half is paid by Ottawa. It is hoped that, as facilities become available, this pressure will induce all Provinces to provide the maximum range of services allowed under the act.

The maximum cost of the program to the Federal Government, with all Provinces participating, has been estimated at \$215 million per year at current prices (4). Provincial governments collectively would provide an equal amount, making the maximum total cost of the program \$430 million, or about 1.3 per cent of the Canadian gross national product. An equivalent figure with regard to the U.S. economy at the present time would be in the region of \$6 billion. Very little of the program cost represents new cost to the economy: it represents rather a consolidation of the expenditures for hospital service formerly made by individuals (either directly or indirectly through insurance), charitable groups, and all levels of government under a number of smaller programs.

The Federal Government finances its share from consolidated revenue; there is no special Federal tax for the hospital insurance program.

The Provincial Agreements

Thus far, only Quebec has failed to take advantage of the new program. Two Provinces, British Columbia and Saskatchewan, have had compulsory hospital insurance plans for some years, and these came into the national program substantially unchanged. Manitoba, Alberta, and Newfoundland commenced their plans on the effective date of the act. The last two of these previously had partial hospital plans—a municipal hospital program in Alberta and the Cottage Hospital program in Newfoundland—which have been incorporated in the new arrangements. Ontario and Nova Scotia started their plans on January 1, 1959, and New Brunswick on July 1, 1959. The remaining Province, Prince Edward Island, is expected to have an operative plan by the end of the year. Plans for the two Federally governed Territories in the north are fairly well advanced, and it is hoped to bring them in early in 1960.

The blueprint for each participating Provincial plan is contained, as mentioned earlier, in a formal agreement signed by both Federal and Provincial governments. This agreement is paralleled by enabling legislation in the Provincial legislatures and forms in effect a contract between the two levels of government. A list of the points that must be covered in each Provincial agreement is specified in the Federal act.

First, a schedule of hospitals which are to provide insured services is specified. These include general, chronic, and convalescent hospitals and such facilities as laboratories and radiological centers, but not mental and tuberculosis hospitals or nursing homes as such. It was felt that individual listing was simpler and more flexible than attempting to define broadly the type of "hospital and other facility" to be included. As well as the scheduled hospitals, which form the majority, there are also listed a small number of contract hospitals (usually company hospitals in outlying areas) which are reimbursed for insured services at an agreed flat rate per capita rather than according to actual expenses. Psychiatric wards in general hospitals can be included, although separate facilities for mental care can not.

The Provincial agreement also lists other acts of Provincial and Federal legislatures which already entitle certain groups of persons to hospital benefits. These include legislation regarding workmen's compensation and benefits for veterans, servicemen, and Royal Canadian Mounted Police. Benefits provided under these special acts are not paid for again by the Provincial hospital insurance plan, although of course the necessary services may be given in Provincial hospitals.

The "scheme for administration" is an integral part of the written Provincial agreement. This includes details of the appointment and duties and responsibilities of the Provincial hospital authority; arrangements for licensing and inspecting hospitals; method of reimbursing hospitals for insured services; and plans for future development of health services in the Province.

Finally, the agreement specifies the range of drugs and biologicals to be supplied in hospitals as part of insured hospital service.

ple, have Provincial arrangements which finance a large part of the hospital's capital cost, while others leave this to local communities, voluntary giving, or market fund raising. With such wide differences in capital costs, it was felt that a program designed primarily to insure hospital services should cover the operating costs only.

There were other subsidiary reasons for excluding capital costs. Sharing capital costs might involve the Federal Government in the difficult and controversial question of who owns the hospitals. It was desired to avoid any charge of nationalizing the hospital system. Also, it was felt that the continued need for local communities and their local and Provincial governments to finance the bulk of their capital costs themselves would insure maintenance of local interest and participation in hospital affairs, and would restrain the urge to build unnecessary facilities in small communities for reasons of local prestige rather than medical need.

Actually, hospitals are not left entirely unassisted with their capital costs. In hospitals employing volunteer labor, there will be considerable surplus on account of salaries which may be applied to meeting interest payments. Federal and Provincial aid with hospital financing under programs unconnected with the hospital insurance program continues. There is also in the act one provision designed to allow a certain amount of "free money" to hospitals to use as they wish. In general, the costs of services not insured by the Provincial plan are not reimbursed by the Provincial authority, since the patient is charged for them directly, but, of the amounts receivable (less bad debts) from patients for accommodation above ward level (representing the extra cost to the hospital of providing this preferred service), only one half must be deducted from total cost. This means, in effect, that the patient is charged for the additional cost of a private room, and then the hospital receives half this amount again from the Provincial authority. In hospitals which provide a considerable amount of non-ward care, this provision will allow a substantial inflow of free funds which may be used for capital purposes.

There are also certain other minor hospital

costs which must be deducted before the hospital's bill is sent to the Provincial authority. In general, all sales and recoveries fall into this category; this might include such items as private laundry, sale of drugs not provided under the Provincial plan, and sale of cigarettes and candy. The hospital cannot charge the Province for functions which are already paid for from other sources, for example, training of personnel to the extent that it is financed by health grants and other governmental programs. The costs of providing noninsured services, such as ambulance service, must likewise be excluded from the hospital's accounting of allowable cost.

Sharable Cost

The Province's hospital bill consists of the consolidated amounts paid to all scheduled hospitals in the Province, as described above, together with amounts paid to the contract hospitals for insured services they provide. Administrative costs of the Province's program, as distinct from administrative costs of individual hospitals, are not included, although some help may be made available for technical consultant and research services under the separate health grants program.

Several more adjustments have to be made, however, before the Province's "sharable cost," the cost which the Federal Government is to share in, is finally determined.

There will be in each Province some hospitalization provided to residents of other Provinces who are insured under the plan of their Provincial government. The costs of these services are reclaimed from the home Province of the persons concerned, and, therefore, must be deducted from the total Provincial cost. A similar deduction must be made for persons treated in Provincial hospitals whose care is already paid for under existing Federal and Provincial acts (for example, veterans and those receiving workmen's compensation), and for those whose care is claimable under the terms of any private liability insurance contract. The purpose of these provisions is to avoid duplication of payment for the same service. Added to the Province's hospital bill, however, are the corresponding amounts paid to other Provinces for care provided to insured persons and, incidentally,

Columbia, cortisone and ACTH. Saskatchewan maintains an approved list of new drugs. All Provinces exclude preparations sold under the Proprietary or Patent Medicines Act. Excluded drugs may, of course, be used in hospitals, but the patient must pay for them.

The Provinces are required to name an authority responsible for the operation of the Provincial plan. In three of them, Saskatchewan, Alberta, and Newfoundland, a division of the Provincial health department has been given administrative responsibility. These three all had hospital plans of greater or lesser scope under their departments of health before the new program commenced. British Columbia, which also had an earlier plan, has retained its separate Hospital Insurance Service which reports through a commissioner directly to the Provincial minister of health, and Manitoba has adopted a similar arrangement. Ontario, Nova Scotia, and New Brunswick have set up independent hospital commissions with membership representative of medical, hospital, labor, and other fields. Prince Edward Island is expected to do likewise.

Hospital Costs

Individual hospitals are reimbursed in full by their Provincial hospital authorities for the operating costs incurred in providing insured services under the Provincial plan. The detailed procedure for making these payments varies among the Provinces. Most Provinces make monthly or semi-monthly advances to the hospitals according to a per diem rate established from the annual budget for each hospital, with necessary adjustments being made at the year's end when the final accounting of actual costs is completed. Ontario tried a dry run in 1958, before payments were actually commenced, to familiarize all concerned with this procedure. Some Provinces differentiate fixed and variable hospital costs, paying the hospital a flat monthly or semi-monthly sum plus an amount varying with the hospital's actual patient load.

All scheduled hospitals in each participating Province are required to render uniform accounts of their costs, which are ultimately audited at both Provincial and Federal levels. Items that seem excessive or unnecessary in re-

lation to costs in other hospitals may be disallowed, although close cooperation between the various accounting units augurs a minimum amount of friction in this respect. A useful byproduct of this system will be the further standardization of hospital accounting procedures across Canada—already made reasonably uniform by use of the Canadian Hospital Accounting Manual—which will eventually yield much valuable comparative information on hospital costs.

The calculation of what the allowable cost actually is in each hospital is naturally a complicated accounting process which cannot be fully described here. Some general features will be described, however, because they are crucial to the financial relationship between hospitals, Provincial hospital authorities, and the Federal Government.

Total hospital costs include all normal operating expenses of the hospital such as wages and salaries, surgical supplies, food, linen, purchases of furniture and technical equipment (other than ambulances), and administration. Volunteer labor, paid nominal or no wages, may be counted as if it were paid in full at going rates, an important provision particularly for hospitals run by religious orders.

The allowable hospital cost, however, does not include interest and carrying charges on the hospital's outstanding debt or depreciation on hospital plant, buildings, and land. This important exclusion in effect restricts the program to current hospital expenses, leaving capital costs to be financed by the hospital itself or the Provincial government as before. Hospital deficits, therefore, are not necessarily wiped out, and the program offers no direct assistance with the costs of construction or hospital expansion.

This exclusion of capital costs is the principal point of controversy in Canada over the act. Why was it decided to do this? Primarily, because no equitable formula could be devised that would include capital costs without unduly favoring some hospitals and Provinces at the expense of others. The amount of outstanding hospital debt and the degree of assistance given hospitals by their Provincial governments differ widely across Canada. Some Provinces, British Columbia, for exam-

Canadian health picture would not be complete without mention of how it affects other Federal health programs and voluntary health insurance.

The health grants program, inaugurated in 1948, is the other major Federal health program. It provides Federal funds and technical assistance to the Provinces for specified health projects and has expanded continuously since its inception (6). The purposes for which the grants are made, together with amounts appropriated for all Provinces in 1959 (7), are:

Purpose	Amount (in millions)
General public health.....	\$8.5
Tuberculosis control.....	4.2
Mental health.....	7.2
Veneral disease control.....	.5
Crippled children.....	.5
Training of health personnel.....	.5
Cancer control.....	3.6
Public health research.....	.5
Hospital construction.....	17.4
Laboratory and radiological services.....	8.5
Medical rehabilitation.....	1.0
Child and maternal health.....	2.0

These grants continue alongside the new hospital insurance program, except that some of them which cover services now a mandatory part of Provincial hospital insurance plans, for example, laboratory and radiological services, now go only to nonparticipating Provinces. Most of the grants are made for specified projects which are subject to Federal approval. In most cases, each Province is allotted a maximum amount under each category of health grant, with provision being made for transfer from one category to another of any surpluses left over.

The grants for hospital construction were doubled shortly before national hospital insurance came into effect and extended to cover costs of constructing interns' quarters and renovating old premises. They now provide approximately \$2,000 Federal funds per bed, with a requirement for Provincial matching.

Some services optional to the Provinces under the hospital insurance program may alternatively be eligible for assistance under the health grants program. For example, several Provinces have chosen to continue rehabilitation programs under the terms of the health

grants program because in this way the programs can be restricted to certain needy groups of beneficiaries; if these activities were included in the hospital insurance program, they would have to be universally available to all residents of the Province.

The medical profession in Canada endorsed the hospital insurance program, guided largely by favorable reports from its members in British Columbia and Saskatchewan who had worked under Provincial hospital insurance plans for some years. Hospitals appear to have reacted favorably. In Quebec, there is reported to be considerable pressure from hospitals for entry into the program, and it is expected that ultimately Quebec will join, making the program truly national in scope.

As might be expected, a radical change has been wrought upon the voluntary hospital insurance picture. At the end of 1957, before the program came into effect, about 7.7 million Canadians had some hospital insurance coverage under private or nonprofit plans. With allowance made for duplication, this accounted for about 52 percent of the population exclusive of Saskatchewan and British Columbia, where compulsory hospital insurance plans were already in effect (8). As of January 1, 1959, the date the Ontario and Nova Scotia plans came into operation, nearly 11 million persons, or 67 percent of the population, were eligible for benefits under the new national hospital insurance program. By the end of 1959, the only Canadians not eligible for benefits will be the 4.6 million who live in the nonparticipating Province of Quebec.

Private insurers and Blue Cross plans continue to write hospital insurance for service above ward level in most Provinces. In Ontario, indeed, the hospital commission has offered to collect premiums for private and nonprofit insurers to facilitate this extra coverage. The new pattern is not yet sufficiently established to know how many persons will purchase additional insurance, but, as an indication, in British Columbia in 1957, about 6.6 percent of the population was covered by voluntary hospital insurance for preferred accommodation in addition to basic Provincial coverage (9). Voluntary insurance for surgical and medical expense is, of course, unaffected.

to hospitals in the United States which treat visiting Canadians.

In the Provinces which charge deterrent fees for hospitalization, the amounts thus collected must be deducted from the total sharable cost, since they represent a part of hospital service paid for directly by the patient.

Once the total Provincial sharable cost has been determined, it is divided by the Provincial population for the per capita cost of hospital services in the Province. Twenty-five percent of this cost and of the Canadian per capita cost are added and then multiplied by the average number of insured persons reported at the end of each month in the year, to arrive at the Federal Government's contribution. In Provinces where the Provincial share is financed through sales tax or general revenue and coverage is universal, the number of insured persons equals the Province's population as estimated by the Dominion statistician. In the premium Provinces—particularly in Ontario, where coverage is partially optional—the insured population must be estimated from enrollment records. At the Federal level, the Canadian per capita cost, which includes all of Canada, is computed from the consolidated returns of all participating Provinces and estimates for the nonparticipating Provinces and Territories.

Hospital Care

The foregoing section should not be allowed to leave the impression that the main emphasis of the Canadian program is financial. All the costing details relate ultimately to the primary purpose of the act—furthering the provision of hospital service in the Provinces.

The actual quality of hospital care provided under the program must constitutionally remain a Provincial responsibility. There is no Federal intervention in hospital management, other than the requirement that Provinces arrange satisfactorily for supervision, licensing, and inspection of hospitals and "make such arrangements as are necessary to ensure that adequate standards are maintained in hospitals" (3).

However, institutions scheduled in the Provincial agreement as hospitals for purposes of cost sharing under the act must be approved by both Provincial and Federal authorities. It is clearly in the interests of the Provinces, as

well as the institutions themselves, to have as many marginal hospitals upgraded to meet Federal requirements as possible. This is expected to be effective particularly in the area of long-term care establishments which might more strictly be defined as nursing homes, but which can provide the type of care for chronic and convalescent patients required by the act. Two such establishments in Peterborough, Ont., were licensed as chronic hospitals for purposes of the act, although most other nursing homes in the Provinces were found to lack the necessary facilities for consideration under the program at present. Parts of institutions that might otherwise be excluded, for example, tuberculosis sanatoriums, many of which now have unoccupied beds, have also been licensed for general care in some parts of Canada. The list of scheduled hospitals and facilities in each Provincial agreement is subject to frequent revision and amendment.

In all Provinces where hospital insurance programs have been newly established, the expected increase in demand for bed space has materialized to some degree. Figures are not as yet available, but nowhere has the shortage of hospital space amounted to a crisis. A part of the increase is expected to be temporary, caused by persons who postponed treatment to take advantage of the new insurance, especially in Provinces such as Ontario where details of the plan were publicized for many months before the plan became effective.

The Ontario Medical Association and others have organized medical staff committees to review admissions and discharges. Some Provinces have had to embark upon an expansion of hospital facilities in order to provide the contracted services. Nova Scotia, for example, had an estimated shortage of 2,000 beds at the time the program came into effect, but with aid from an expanded health grants program has already made up 1,300 of this deficiency. Each Provincial agreement is required to outline the Province's plan for organized expansion of facilities in the future, an incentive to the orderly development of Provincial hospital service.

The Health Field

An account of the way in which the new hospital insurance program has fitted into the

Stream Life Below Industrial Outfalls

WILLIAM MARCUS INGRAM, Ph.D., and W. W. TOWNE, M.S., C.E.

The following brief review of present knowledge of the biological effects of industrial wastes in water is offered in anticipation of publication of a detailed book on this subject. The text will cover methods of presenting biological data (touched on here) and sampling equipment indicated for stream surveys. It will carry a full bibliography. Only a few outstanding references are cited in this article.

THAT DAY is dead when it seemed only natural and logical for Americans to discharge raw industrial wastes to the most convenient stream. The recognized need to protect the Nation's basic and essential water resource has brought all artificial additions to the stream under critical scrutiny. The present task is to establish reasonable appraisals of the various effects of specified industrial effluents. Conversely, we seek to learn how certain biological effects may serve as indicators of forms or degrees of industrial pollution in a stream.

What are the outstanding detrimental effects of industrial wastes on aquatic life? How do certain nutrient wastes contribute to the growth of biological nuisances? Comments on these questions are offered with confidence that they will be viewed in the large perspective that embraces all forms of stream pollution, including those provoked by improvident abuses of the

Dr. Ingram is in charge of biological field investigations, Field Operations Section, and Mr. Towne is deputy chief of the Technical Services Branch, Division of Water Supply and Water Pollution Control, Robert A. Taft Sanitary Engineering Center, Public Health Service. The full paper on which this article is based was presented at the 14th Annual Purdue Industrial Waste Conference in May 1959 at Purdue University, Lafayette, Ind.

land, excessive use of water, and failure to regulate streamflow. The contribution of domestic sewage and the scouring effects of peak flows also are assumed as being understood in the general context of these remarks.

The major emphasis here falls on four factors in industrial wastes that are responsible for the most subtle environmental effects: elevated temperature; particulate matter, contributing to turbidity and the formation of settleable solids; nutrients, favoring blooms of aquatic weeds and pests; and radioactive elements. These conditions in turn produce forces damaging to the productive use of the water resources.

Elevated Temperatures

The effect of a mild heating of natural waters, its influence on the metabolic processes of biota as reflected in measurements of oxygen demand, oxidation, and reaeration, has long been recognized, if not fully understood. As temperature of water rises, oxygen becomes less soluble. Under a pressure of 760 mm. in fresh water, the concentration of dissolved oxygen at 0° C., is 14.62 ppm; at 20° C., 9.17 ppm; at 39° C., 7.63 ppm. The mere heating of a stream can deny stream life its normal supply of oxygen. Coupled with putrescible pollution, which increases the total demand for oxygen, a rise in temperature may deplete the oxygen level to a stage of asphyxiation for aquatic organisms, which cannot survive in such competition.

Another subtle effect of a rise in temperature is reflected, on occasion, in the increased toxicity of certain chemicals. For example, exposed to 0.4 ppm rotenone, brown trout die in 15 minutes at 21.11° C., in 70 minutes at

Blue Cross, as such, has virtually disappeared in most of Canada. However, the disappearance may be more in name than in fact, because the personnel, records, and experience have in most cases been absorbed directly into the new Provincial hospital organizations. In Ontario, for example, the 500 employees of the old Ontario Hospital Association's voluntary plan have all been transferred to the new Ontario Hospital Commission and continue to perform the same function on a larger scale.

The new hospital insurance program has been called by one Federal official "the most significant development in the health field in Canadian history" (4). It clearly goes far toward meeting what Hon. J. Waldo Montleith, Minister of National Health and Welfare, termed "the obvious needs of Canadians for an orderly and economic means of obtaining basic hospital care" (10). Because of the close similarities between Canadian health needs and our own, the further development of this experiment will bear close watching from the United States.

Grants for Extramural Research in Nursing

Ten new awards, totaling approximately \$250,000, have been granted for extramural research in nursing by the Public Health Service, bringing to 73 the total of grants awarded under the nursing research grants program since its inception in 1955. Awards to persons outside the Service for studies on nursing and improvement of patient care, now amounting to \$3 million, are administered by the Division of Nursing Resources in cooperation with the Division of General Medical Sciences of the National Institutes of Health.

The recent awards are for studies on cardiac and psychiatric nursing, nursing education (including improvement of research competence), and the educational and socioeconomic factors affecting nurses.

ville. Seines and various dip nets in the reach of the Mahoning from below Warren through Lowellville in September 1952 failed to take fish when industry was discharging wastes, including hot water, in addition to raw municipal sewage. At this time, several chemical and physical factors, in addition to heat, could have been considered equally lethal or detrimental to fish, for example, pH as low as 2.4, dissolved oxygen as low as 0.2 ppm, and various high concentrations of industrial and municipal sewage solids.

In July during the extended steel strike, when pollution was largely produced by raw domestic sewage, although there were also residual industrial effects, fish were taken at Girard and above Indian Run Creek in Youngstown. At Girard temperatures varied from 23.5° C. to 29.5° C.; dissolved oxygen varied from 5.0 to 5.6 ppm; and pH from 6.9 to 7.4. Northern creek chub and goldfish were taken at Girard. Fish taken at the Indian Run Creek station under comparable temperatures and pH and dissolved oxygen ranges were the large-mouth black bass and the common shiner. At upstream control stations above Leavittsburg in July and September, with stream temperatures varying from 24° C. to 31° C., the dissolved oxygen from 5.7 to 6.9 ppm, and the pH from 7.0 to 7.6, sampling obtained a variety of fish: white crappie, small-mouth black bass, northern creek chub, green sunfish, northern black bullhead, bluntnose minnow, and golden shiner.

A field survey of the fisheries related to heat discharged by the New Johnsonville steam plant on Kentucky Lake indicates that a localized warming effect, over that of contiguous waters in the impoundment, served to attract fish and help them survive during cold-water periods (11). Warm water from the steam plant may serve as a winter refuge for threadfin shad. These fish abounded in the steam plant discharge harbor, warmed by condenser water discharges to 12.78° C., when other water of Kentucky Lake was 7.22° C.

Information on the effects of hot condenser water discharged from a steam-electric generating plant to Martins Creek, Pa. (which, in turn, feeds heat to the Delaware River), so far has been inconclusive (12). These studies are continuing. An example of temperature

dissipation in the area of the Delaware illustrates how rapidly temperature can be dissipated in a flowing stream, although the situations described are never exactly repeated. At a railroad bridge 1,500 feet below the heat source, the maximum temperature was 32.22° C., at 2,000 feet 30° C., at 2,750 feet 22.78° C., at 3,600 feet 21.66° C., and at 4,500 feet 20° C. The initial temperature of discharge water is not available.

Particulate Matter

Turbidity, which is considered to be an expression of the optical property of water which causes light rays to be scattered and absorbed rather than transmitted in straight lines, is increased by various forms of particulate matter in suspension (fig. 1). Such matter may include phytoplankton or zooplankton cells, such as algae and protozoans, or silt or other fine materials. Particulate matter in any form that settles to form organic or inorganic sludge is described here as "settleable solids." These solids include matter which increases turbidity.

Many industrial operations contribute settleable solids to water. Apart from the chemical activity that may be provoked in water by such particulate matter, the physical effects on aquatic life are often severe. Some industrial discharges of particulate matter are coal and other mineral products, including washery by-products; glass sand; lumber; aluminum, steel, and other metals; pulp and paper; wastes from slaughterhouses, canneries, tanneries, and dairies; and oil.

Since such wastes in suspension limit the penetration of sunlight, they impede the growth of aquatic plants attached to the bottom as well as floating or weakly swimming algal forms. Being photosynthetic, these organisms depend on light for existence. Solids also floc planktonic algae and even surface animals and carry them to the bottom to die. By limiting growths of aquatic plant meadows, the wastes starve organisms which feed there. The food chains are interrupted, and aquatic life in general becomes sparse.

As particulate matter settles, the deposits can blanket the substrate. Such a physical en-

12.78° C. With dosage of 0.2 ppm, they die in about 22 minutes at 21.11° C. and in 100 minutes at 12.78° C. (1). But this gain in toxicity with heat is not the rule for all chemicals or species. At 10° C. and 25° C., there is no observed change in the toxicity of ammonia to clabs. Further, it has been demonstrated that toxicities of potassium dichromate and naphthene acid were similar at 18° C. and 30° C.

For students of the effects of temperature on fish, laboratory studies offer a wealth of data which cannot be summarized here, but several such summaries are in the literature (2,3). J. R. Brett's "Some Principles in the Thermal Requirements of Fishes" is an especially useful and comprehensive review of this subject (2).

In industrial waste field surveys of large streams, it may be difficult to relate detrimental effects of temperature (heat pollution) to specific aquatic organisms. In bodies of water, such as the Mahoning River in Ohio, where temperatures become high enough to be lethal to most aquatic organisms in outfall areas, deleterious conditions arise also from other factors, such as low dissolved oxygen, high turbidities and settleable and floating solids, and pH and chemical toxicity.

Hot industrial discharges can be disastrous to fish. Also, high temperatures may alter the entire biosphere. By eliminating many organisms, heat may allow a few, such as the heat-resistant blue-green alga, *Phormidium*, to become dominant. Ranges in which algae are known to grow best in general are from 18° C. to 30° C. for diatoms, 30° C. to 35° C. for greens, and 35° C. to 40° C. for blue-greens. Some species grow at even higher temperatures (4). Gross limits of temperature (5) that most warm-water fish experience in natural bodies of water are somewhere between 0° C. and 35° C. (32° F. to 95° F.). If water of 30° C. is available, warm-water fish may seek it, leaving 32° C. water. Among warm-water fish are sunfish, catfish, carp, and many minnows. Cold-water fish, such as the salmonoids, salmon and trout, normally live in natural waters that range between 0° C. and near 18.34° C. (summer temperature). They usually do not tolerate temperatures above 27.23° C. Certain trout have been reported as surviving temperatures of 27.78° C. to 28.34° C. for very

short periods in natural water (5,6). The Aquatic Life Advisory Committee of the Ohio River Valley Water Sanitation Commission, referring to waste discharges, recommended that temperatures not be raised above 34° C. (93° F.) "at any place at any time," and stated that temperatures during December, through April should not exceed 23° C. (73° F.) "at any place or at any time" (7). The report emphasizes that natural temperatures must be maintained in streams suitable for trout propagation.

No one knows precisely how varying temperatures affect all the biota of a stream. However, in general, it appears that in most temperate zone streams of low gradient, large reaches should not exceed 30° C. for prolonged periods, and that headwater streams ought not be warmer than the top range of 22° C. to 25° C. for extended periods. Further research is more likely to reduce than raise these limits (8).

As examples on record of streams affected by high industrial heat discharges, one can mention the Mahoning River in the Warren-Youngstown, Ohio, reach; the Kentucky Lake site of the New Johnsonville steam plant, Martins Creek, Pa., site of the steam-electric generating plant on the Delaware River west bank several miles downstream from Belvidere, N.J.; and the waters near the Front Street power station at Erie, Pa.

Temperatures in the Mahoning River have exceeded those tolerated by fish and other aquatic organisms. The "Ohio River Pollution Control" document prepared by the Public Health Service states, "During periods of low streamflow the water temperature below Youngstown has risen often to over 43.34° C." (9). It is reported in "Water Resources of the Mahoning River Basin" that, when the last of four reservoirs went into operation, flows have been such that the maximum daily temperatures have only occasionally been above 37.78° C., and that monthly mean temperatures have been below 36.66° C. (10). During a survey in July and September 1952 of the Mahoning (Pricetown to Lowellville reach) in which Ingram participated, maximum temperatures for 13 stations occurred in September and were 35.1° C. at Struthers and 34.5° C. at Lowell-

a rich diet of insects which, in turn, enjoy numerous algal species. The main observation is that there is a great variety of species represented by a few individuals of each form.

In the zone of degradation, floating solids blanket out the light penetration. Moving into the zone of active decomposition, as these solids settle, sludge blankets the entire bottom. Turbidity makes the water almost opaque. Only a few species can survive in the soft, shifting sludge. Being isolated from most competitors and predators, a few species here form huge populations. The few animal forms that thrive in a sludge substrate are bloodworms, *Tubifex*, and *Limnodrilus*; water sow-bug crustaceans, *Asellus*; certain left-handed snails; and various leeches. Fish are absent or scarce. They prefer to nest elsewhere. Aquatic plants are not able to root. Species of algae are extremely limited: blue-greens, such as *Phormidium* and *Oscillatoria*, form gelatinous shiny blankets over the sludge in shallow marginal water. Only an occasional plankter moves

through the water in the zone of active decomposition; most have been dragged out of the upstream water in the zone of degradation to suffocate in the clinging wastes.

A detailed description of a bottom covered with inert inorganic solids suggests an aqueous desert rather than the jungle of bloodworms found in organic sludge. Data collected in September 1952 (fig. 3) and again in September 1958 portray the physical effect on aquatic life of waste from a glass-sand operation on a small creek feeding the Potomac River. Below this creek reaches a submarine Sahara, dotted with a few rare oases. In 1958, above the point of confluence, the Potomac was sparkling clear, bedded by a bottom of rocky ledges, rocks, coarse gravel, and some natural clean sand, lush with beds of higher aquatic plants, such as *Elodea* and *Potamogeton*. Gill-breathing snails and mayflies dominate invertebrate life everywhere on the substrate. Large unionid, pearl-button clams dot the margin. Minnows swarm in the sunlight. The filamentous alga, *Clado-*

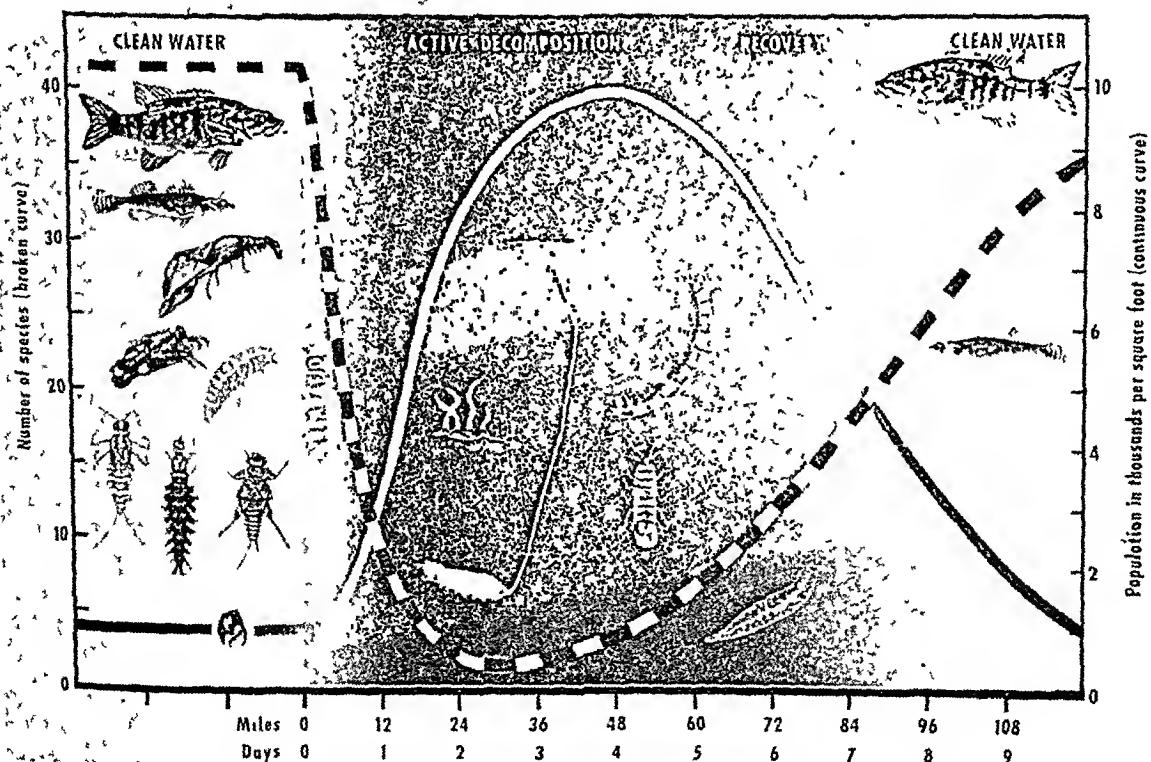

Figure 2. Biological effects of organic sludge

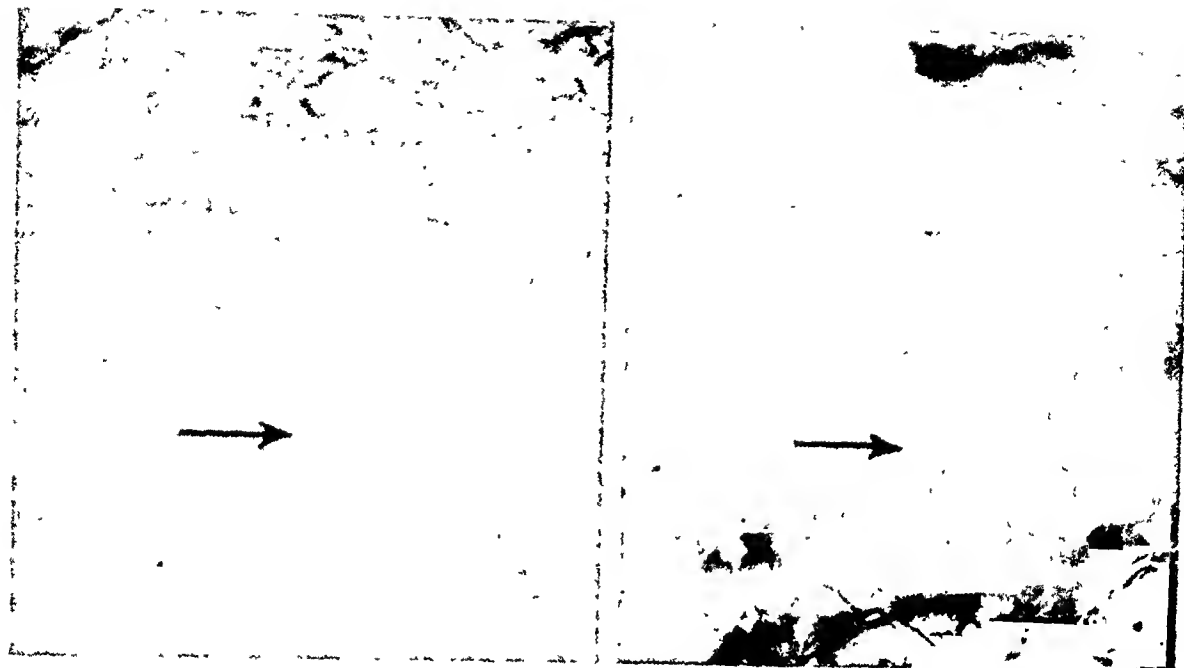

Figure 1. Stream turbidity

(Left) Arrow points to a dime in clear water of Potomac River with low turbidity. (Right) Dime is obscured by high turbidity resulting from inert particulate matter discharged from an industrial operation.

vironment is unacceptable to organisms that would normally occupy such a habitat. Not only industrial wastes but also silt produced by soil erosion is said to alter aquatic environments, chiefly by screening out light, by changing heat radiation, by blanketing the stream bottom, and by retaining organic material and other substances which create unfavorable conditions at the bottom. Also, it has been stated that the developing eggs of fish, as well as fish food organisms, may be smothered by deposits of silt (1). Direct injury to fully developed fish apparently by nontoxic suspended matter has been demonstrated only in tests with concentrations which are uncommon (2).

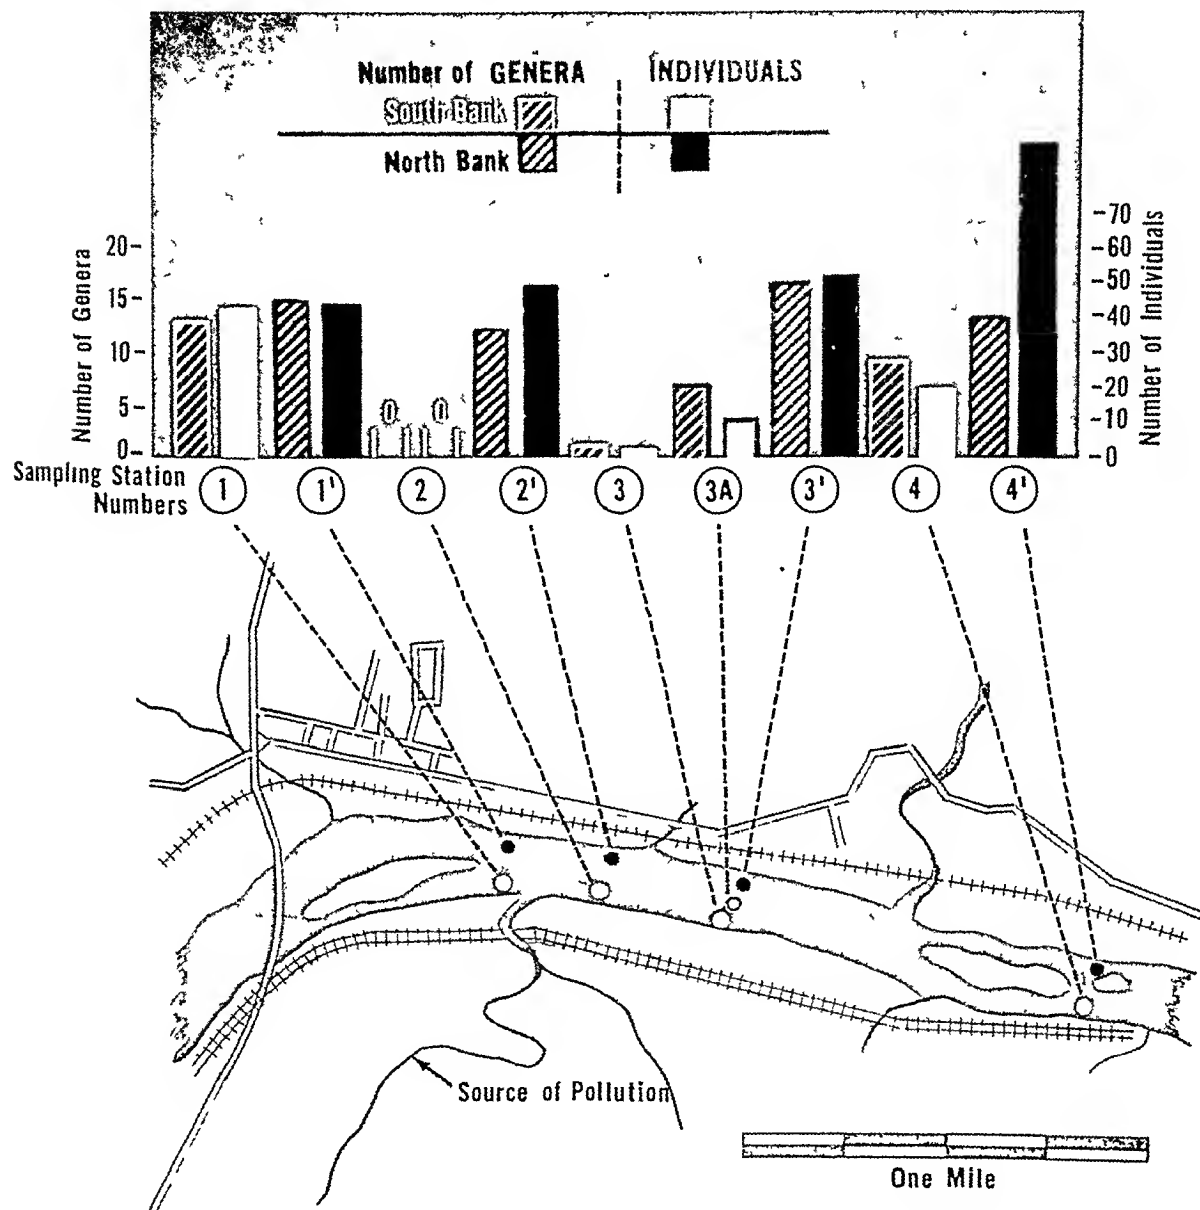

Quite different physical effects on stream life result if the bottom blanketing deposits are dominantly organic rather than inorganic. If they are not highly toxic and if the supply of dissolved oxygen is satisfactory, soft organic sludges will give rise to organisms adapted to that environment. On the other hand, inert solids, such as glass sand and other mineral wastes, destroy bottom life. Fewer organisms can live among compacted, heavy abrasives characteristic of such wastes. These wastes may actually simulate "ball-mills," grinding

and crushing life that is contacted on a stream bottom, as they are resuspended and moved downstream by periodic surges of high water.

The physical effects of organic sludges of industrial origin are partially illustrated in figure 2, describing a hypothetical situation based upon specific data gleaned from field investigations. It is assumed, for this discussion, that the deposits are not appreciably toxic and that the dissolved oxygen resources are adequate for aquatic life. Settleable solids enter the stream at mile 0 and organic sludge deposits of maximum thickness are formed in the zone of active decomposition between miles 12 and 48. Turbidities are highest between miles 0 and 12. Sludge deposits are not significant elsewhere, and turbidities elsewhere are also unimportant.

In the clean water zones, the bottom is composed of small and large stones. Here a multitude of different species of bottom organisms, plankton, and fish abound. Typical of the species on this bottom are caddisfly larvae, stoneflies, mayflies, hellgramites, gill-breathing snails, and unionid clams. There are many spots where fish may nest. Small-mouth black bass, sunfish, and various minnows flourish on

Figure 3. Physical effects of glass-sand operations, Potomac River, September 1952

NOTE: This pictorial map combined with vertical bar graphs showing variations in bottom animals per square foot in a section of the Potomac River illustrates use of a graph to demonstrate the impact of pollution on aquatic life, replacing a long list of names of animals and plants found in an affected stream. The presentation shows sampling stations in relation to roads, railroads, and towns. The effects of inert, inorganic solids in limiting the number of animal genera and individuals (stations 2-4 on the south side of the

river) are compared with their abundance at stations in unaffected stream areas (1 on south side and 1'-1'' on the north side). Stations 1 and 1' are used as controls. Solids are carried into the main river from the tributary at the confluence between stations 1 and 2. Bottom animals are absent at downstream station 2. Only 1 genus was collected at station 3 on the south half of the bottom, while 7 genera were taken in the center of the river (3A) and 16 genera on the bottom of the northern half of the stream (3').

phora, covers much of the rocky area. Eleven genera of planktonic and filamentous algae and eight genera of animals are represented in our collections from this station.

At a station 600 yards below the confluence of the small creek (receiving glass-sand wastes) with the left bank of the Potomac, the bottom of the river was devoid of life in 1958, as it was in 1952. Blue-green algae grew marginally on the wave-wash area of the bank. This paucity of organisms extended to midstream, where 3 genera of snails and 10 genera of planktonic algae were collected. From the left bank (looking upstream) to the midstream rocky ledges, the rocks, gravel, and sand of the original Potomac River bottom were covered completely up to 2 feet deep by waste glass-sand fines. During the period when samples were collected in 1958, the sand lines desert was spectacular in clear water. Turbidities attributable to this operation were found to vary tremendously in 1958 with waste discharges, from 130 turbidity units to 50,000 turbidity units. The effects of such discharges in 1958 were observed to suppress bottom life as far as 10 miles downstream.

Excess of Nutrients

Overproduction of any plant or animal is a sign of an unbalanced ecology. The degree of disequilibrium may be a portent of disaster as when a rise in human population taxes a land's limited natural resources. Likewise overpopulation of a lake with shad may present a sudden and unwelcome abundance of protein at the shore.

Wastes with substrates of nitrogen, phosphorus, carbohydrates, and fats may have the potential of forming through hydrolysis in enzymatic systems, readily available end products of organic foodstuffs such as amino acids, simple sugars, fatty acids, and glycerol. These feed animals or stimulate aquatic plant growth. Such wastes may build up such a plant or animal nuisance growth that water uses are impaired. Organisms that flourish typically with certain of such nutrients are the sewage bacterium, devil grass (*Sphaerotilus*), and certain planktonic and sessile algae.

Algal and *Sphaerotilus* blooms that interfere

with multiple uses of water result from a nutritional process that is not immediately relevant. However, the damage they do is likely to continue, and other nuisances may ensue. If streams, lakes, and manmade impoundments continue to be enriched with wastes of industrial, municipal, and agricultural origin, biological nuisances will be intensified and new unspoiled areas will suffer.

Sphaerotilus, the filamentous-plumose flocc-forming bacterium, is not now susceptible to control. Research has not revealed treatment methods that have been productively put into operation on a plant-scale basis, either to prevent or eliminate the growth, despite the best efforts of the pulp and paper industry to foil this gelatinous pest (14, 15).

Sphaerotilus abounds in certain reaches of the Columbia River in Washington and Oregon; Altamaha River, Ga.; Hiawasee River, Tenn.; New River, Va.; Penobscot River, Maine; Clearwater River, Idaho; Fox and Menominee Rivers, Wis.; and Bear River, Utah.

It occurs in restricted patches in the Connecticut River, Mass.; Ohio River, downstream from Cincinnati, Ohio; Grass River, N.Y.; Potomac River drainage in Maryland; South Holston River, Tenn.; as well as in smaller streams throughout the country.

Without an inventory to indicate the current abundance of *Sphaerotilus* in waterways of the United States, there can be no valid assessment of its distribution and the magnitude of its nuisance value. Too, only such an inventory can relate the subtlety of its development to bloom proportions to nutritional substrates from various types and combinations of waste and runoff.

Sphaerotilus has become recognized as a pest in recent years principally because of its interference with both commercial and sport fishing. Its effect on the gill-net commercial fisheries of the Columbia River is notorious. Specific complaints have been voiced also by fishermen on the Altamaha River in Georgia and the New River in Virginia. The major realistic objection is that *Sphaerotilus* flocs, entangled in fishing gear, hinder the catch and add to the work (16).

Sphaerotilus, in forming blooms, especially

dustries that used lake water had to install expensive "filtering and purifying systems" to remove the organic matter and overcome obnoxious tastes and odors. Oxygen in the deeper water declined so that trout and one species of whitefish disappeared, and two other species of whitefish became scarce. Other species, largely coarse, replaced the sought-after game fish. The shallower basin, Obersee, which received no urban drainage, is reported to have retained its "virgin-lake" characteristics and has changed but little. Unwitting fertilization not only causes nuisances, but hastens the extinction of a lake by accelerated sedimentation, according to records for 37 lakes in the United States, Austria, England, Finland, Germany, Italy, and Sweden. In these lakes, eutrophication within several decades has entailed disagreeable consequences similar for the most part to the events in Lake Zurich (19).

Effects on lakeside dwellers have been well documented for algal blooms on certain lakes near Madison, Wis. Especially during hot summer periods, lakes assume the appearance and consistency of thick green pea soup. At such times, the reaction of bathers, sailors, and fishermen may be imagined. The unsightly masses of green as they decompose, also produce vile odors that make life in the area hardly tolerable (20).

Algal blooms have been responsible for massive fish kills by reducing the resources of dissolved oxygen. During daylight hours, algae and submersed aquatic plants give off oxygen by photosynthesis, commonly raising the dissolved oxygen resources to supersaturation levels. But photosynthesis does not proceed during hours of total darkness although respiration continues. In streams with huge algal blooms, dissolved oxygen in these circumstances may be reduced below survival points. In Lytle Creek, Wilmington, Ohio, dissolved oxygen fluctuated over 24 hours from 19.4 ppm in the afternoon to 0.7 ppm before dawn. A fish kill in this creek was attributed to oxygen depletion, largely by algal respiration (6). Fish kills under similar conditions have been reported for East Okoboji Lake and Storm Lake, Iowa (21), and other such disasters have occurred in the Ohio River Basin (22).

Radioactive Wastes

Recommendations as to maximum levels of radioactivity in water or aquatic organisms are outside our province, except for the general acceptance of the principle that any addition to the prevailing burden of radiation should be judiciously considered, and that unnecessary additions be eschewed. Rather than evaluate the effects of given quantities of radioactivity, this discussion is confined to the quality or character of the process by which certain nuclides, through biological adsorption and absorption, are cycled into human food chains, as shown in figure 4 (23). By such processes, radioactive atoms are concentrated to relatively high orders of magnitude by organisms living in blooms in natural waters.

Concentration of radionuclides in edible fish and their subsequent lodging in human tissue is readily visualized. Less obvious is the potential transport of radionuclides into human tissues after algal blooms have increased the concentration in raw-water sources. Even though such blooms are caught on rapid sand filters and backwashed to carry them out of the drinking water supply, there remain opportunities for radionuclides to pass through the filters into finished water. As algal cells fragment on filters, they may release atoms in solution in the drinking water. Also, water supplies without treatment other than chlorination can carry algal cells with adsorbed and absorbed radionuclides directly into the drinking water supply.

Davis and Foster have cautioned that the recommended maximum concentrations of radioactivity in water do not in themselves limit the degree of biological concentration: "With an increasing number of atomic energy installations and their associated problems of disposal of liquid wastes, we recognize that more and more aquatic environments are going to be exposed to at least low concentrations of radioactive materials. For the safety of human populations who may be drinking water which contains such radioactive materials, a set of maximum permissible concentrations has been recommended (International Commission on Radiological Protection, 1955). By themselves, however, such recommendations are in-

in riffle areas with other associated bacterial slimes, may blanket the bottom, "crowding out" fish food organisms and spoiling potential fish nesting areas.

Prospective difficulties from *Sphaerotilus* are: (a) clogging of rapid sand filters of municipal and industrial water treatment installations, (b) tastes and odors in water produced by decay, (c) mucilaginous nuisances in pumping stations and in irrigation canals, and (d) contact nuisance to swimming, water skiing, and boating.

The process by which excess nutrients are released to create algal and rooted aquatic plant nuisance growths can be diverted rather than inhibited. In modern waste treatment practices, dissolved inorganic or mineral constituents of municipal sewage and industrial wastes are removed only incidentally by sedimentation and oxidation. Also certain organic materials are broken down, with treatment, to liberate inorganic nitrogen and phosphorus. Treatment plant effluents may actually contain more readily available nutritional substrates than are found in raw sewage effluents. In order to limit the fertilizing effect of sewage and of certain nontoxic industrial wastes, such wastes ideally should be excluded from natural lakes and impoundments. Despite exclusion of nutrient-bearing wastes, agricultural drainage, carrying nitrogenous and phosphorous compounds, will especially provide nutrients that may encourage green aquatic plant nuisances.

It has been shown that, if assets of inorganic nitrogen and phosphorus exceeded 0.30 and 0.01 ppm, respectively, at the start of the active growing season (the time of spring turnover in northern climates), a season with nuisance algal blooms could follow (17). This suggestion was made following 2 years of study on 17 lakes in southeastern Wisconsin. While it does not apply to all lakes, it has stimulated other investigations.

The facts today indicate that, with continual nutrient enrichment of waters, algal nuisances have only begun to demonstrate what they may become in future years. Domestic sewage alone may vary in its nitrogen content from 15 to 35 ppm and in phosphorus from 2 to 4 ppm (18). In relation to these nutrients, it has been stated:

"A large percentage of these fertilizing elements exists in a readily available condition or becomes so during biological treatment or while undergoing stabilization by microorganisms in the receiving body of water. Consequently, it can be reasoned that sewage contains nitrogen and phosphorus in a ratio of about 8 to 1" (18). Data on increments of nitrogen and phosphorus from various industrial operations are not at hand but the total contribution of industrially produced chemicals offers many complications to the biochemistry of the water resource.

Specific contributions by agriculture of nitrogen and phosphorus to bodies of water by runoff are not known. However, data provided by the U.S. Bureau of Reclamation points to increments of nutrients in the soil. A 1955 estimate of an average use of fertilizer per irrigated acre in California is 382 pounds, of which 42 pounds per acre are nitrogen and 26 pounds per acre are P_2O_5 .

The effects of algal nuisances have long been known to the waterworks field. Algal blooms cause tastes and odors in water, clog rapid sand filters, and form unsightly scums on basins in water treatment installations. In future years, those charged with management of water projects, such as the many multiple purpose reservoirs that are being constructed in this country, are likely to encounter a variety of biological nuisances, especially algal blooms, nurtured by nutrients introduced by man. In summarizing information on European lakes, the data suggest the potential biological nuisance that can arise, with time, in our reservoirs (19). But little has been published on lake fertilization (eutrophication) to show systematically the effects of nutrients on the lake ecology and on the uses of lake water.

Lake Zurich, Switzerland, composed of two arms connected by a narrow channel, less than 100 years ago is stated to have been clear and clean, supporting trout and whitefish. Since the turn of this century, urban drainage from small communities totaling about 110,000 persons has been discharged to one arm of this lake. Beginning in 1896, algal scums formed that were malodorous as well as unattractive. The lake ceased to be enjoyed for bathing, boating, and general recreation. The cities and in-

could not accurately be predicted. Results indicate that concentration of very short-lived isotopes is of limited consequence in higher organisms such as fish. Radiophosphorus, on the other hand, is concentrated more than 100,000 times. Although the P^{32} is highly concentrated, existing amounts in the Columbia River are well below dangerous levels. Even in the most radioactive section, the young fish receive only about 0.1 rad per day from beta emitters—far less than the amount which would produce discernible damage. Both laboratory and field studies of river forms have shown no injurious effects from the presence of the reactor effluent. It is questionable that widespread decimation of aquatic populations will occur from radiation damage in situations where contamination levels in fish must remain below maximum permissible levels for human food. The difference in the activity density of Columbia River fish over that of the water, owing to the tremendous power of aquatic forms to concentrate some radioisotopes, illustrates the need for careful consideration of potential hazards prior to disposal of liquid wastes to public waters. If radiophosphorus were allowed to reach the maximum level permitted for drinking water, organisms living in the water would suffer radiation damage and the fish would be unsafe for human food. The seriousness of radioactive contaminations in an aquatic environment depends not only upon the quantities of individual isotopes which may be released but also upon the physical, chemical, and biological properties of the water. Where contamination of a river or lake may be significant, careful investigation of each particular case is essential since complex biological processes may introduce hazards not included in such conventional limits as permissible concentrations for drinking water."

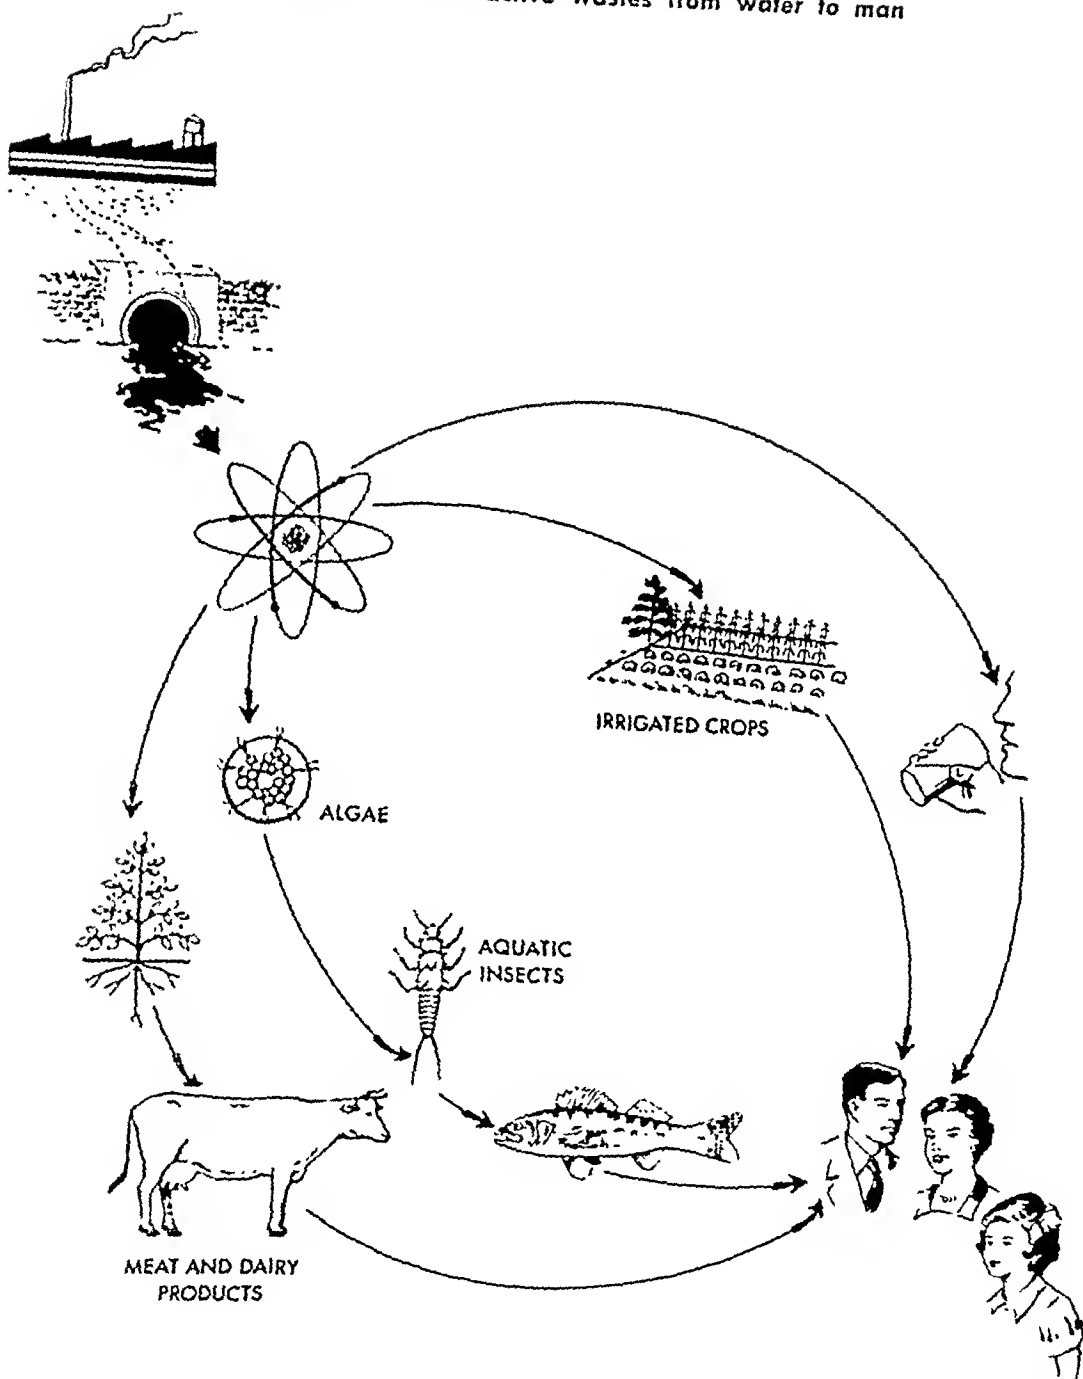

For the immediate future, increased radioactivity in streams is likely to cause little apparent damage to aquatic life or human welfare. The long-range prospect, however, even on the basis of present burdens of radiation, offers no grounds for complacency or assurance.

adequate to define completely the radiological hazard which may develop through aquatic food chains. Where biological systems are involved, the organisms may accumulate certain isotopes to many times the initial concentrations in the water" (24).

The International Conference on the Peaceful Uses of Atomic Energy enlarged upon information pertinent to this discussion (25): "Extensive studies have been made of the radioactivity in river organisms below the Hanford reactors, since the radiation levels

could not accurately be predicted. Results indicate that concentration of very short-lived isotopes is of limited consequence in higher organisms such as fish. Radiophosphorus, on the other hand, is concentrated more than 100,000 times. Although the P^{32} is highly concentrated, existing amounts in the Columbia River are well below dangerous levels. New Index Medicus

The indexing activities of the National Library of Medicine, Public Health Service, and the American Medical Association will be coordinated, according to plans approved by the Board of Regents of the library and the House of Delegates of the American Medical Association. The cooperative arrangement will go into effect in 1960.

Beginning with the January issue of that year, the National Library of Medicine will publish monthly issues only of a new medical index to be called the *Index Medicus*. The American Medical Association will issue annual cumulations of the index, to be known as the *Cumulated Index Medicus*.

Each monthly issue of the *Index Medicus* will contain entirely new material. The coverage of this index will be substantially increased over the present 110,000 to 120,000 articles in the *Current List of Medical Literature*.

After completion of the December 1960 issue, the library will rearrange and realphabetize by machine the contents of the year's 12 issues of the *Index Medicus*. The rearranged material will then be photographed by a high-

speed step camera, and the film copy will then be transferred to the American Medical Association for direct use in the preparation of printing plates.

In 1879, publication of a monthly index to the periodical literature of medicine, the *Index Medicus*, began at the National Library of Medicine. In 1916 the American Medical Association commenced publication of a quarterly index to medical periodical literature under the title *Quarterly Cumulative Index*. In 1927 the two publications were combined under the joint sponsorship of the library and the medical association to form the *Quarterly Cumulative Index Medicus*. Since 1932 the medical association has been solely responsible for publishing the quarterly index. With volume 60, covering the period July-December 1956, publication of the quarterly will cease.

Subscriptions for the *Index Medicus* will be handled by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C.; the *Cumulated Index Medicus* will be distributed separately by the American Medical Association.

An essay on the forces of nature observed by research biologists working on the treatment of waste highlights the dramatic challenges of sanitary engineering.

Observations and Speculation on Waste Treatment Research

BERNARD B. BERGER

GILBERT WHITE, the great English naturalist of the 18th century, noted that dung dropped by cattle standing in ponds became food for aquatic insects, which in turn became food for fishes. He observed: "Thus nature, a great economist, converts the recreation of one animal to the support of another" (1).

The phenomenon of the food chain which so impressed itself on the good Reverend's attention is still of enormous interest to biologists, particularly to those working in the field of waste disposal. Certainly we have gained a great deal of sophistication in biology in the last few centuries. Our colleagues in the biological sciences speak now of ecologic systems, food chains, food webs, energy flow and balances, and material transformations. Our knowledge has been vastly extended in phenomena related to the interdependence of species and in all the subtle, delicate mechanisms by which micro-organisms react to their environments.

For approximately one-half century, our col-

leagues and our predecessors have been applying their best knowledge to creating optimum environments for the satisfactory disposal of human wastes. We now have at least a basic understanding of the biological communities on which we depend for waste stabilization. We have rational and intellectually satisfying procedures for designing trickling filters, activated sludge systems, and waste stabilization ponds for the intensive bio-oxidation of putrescible materials, and in a reasonably accurate fashion we may predict a stream's ability to assimilate such materials. Much has been accomplished, therefore, since the Reverend Gilbert White made his shrewd observation. However, it must be admitted we are still a long way from desirable control of the biological processes of interest, particularly with respect to new organics with which our microbial communities have had no experience.

In the course of our striving to understand and to control this biological action, many observations of interest have been made and we have speculated long as to their nature. In discussing some of these odd observations, what I have to say represents my own views and not necessarily those of the biologists with whom I have been associated. It is, perhaps, much easier for me, a sanitary engineer and in a sense an outsider, to speculate on this subject. This I shall proceed to do with a free hand.

Mr. Berger is chief of the Research Branch, Division of Water Supply and Water Pollution Control, Robert A. Taft Sanitary Engineering Center, Public Health Service. This paper was presented at the Manufacturing Chemists' Association meeting in Cincinnati, Ohio, March 18, 1959.

Although many of you have seen a trickling filter in a sewage treatment plant, probably few have ever run fingers through the slime covering on the filter rock, wondering what was in it and how it could be so effective and so reliable in treating highly putrescible human wastes. This organic film is obviously a filthy, slimy mess, but it holds great interest for the biologist. Dr. Bridge Cooke, our mycologist, recently completed an intensive study of the surface of trickling filters serving Dayton, Ohio, and what emerged from his report was an entrancing picture of a jungle in microcosm (2).

The slime was virtually a reproduction of the earth surface, especially with respect to the harsh competition for survival among organisms. The fungi in the slime held tightly to the underlying rock and gave the slime its structural strength. Filamentous algae likewise gave support to the slime layer. The fungi were akin to jungle trees, and the filamentous algae akin to green foliage. Broad savaunahs were represented by extensive growths of surface algae. A variety of protozoa and higher animals browsed among the diverse plant life, and still others preyed indiscriminately on microscopic forms. Feeding on everything they contacted were insect larvae, worms, and snails. Here, in the slime, as in our familiar life, it is an eternal struggle for survival. Fortunately for us, the survivors represent a well-balanced energy and material flow, assuring good waste treatment.

The presence of the algae in the slime film was especially interesting. Obviously, they were thriving. Through their photosynthesis they were producing oxygen, much of which presumably remained dissolved in the film. Could this oxygen possibly be of any use in supporting the respiration of the micro-organisms feeding on the organic wastes? What gave point to this question was the common knowledge that the interface between the slime film and the atmosphere presents a barrier to oxygen movement. Here at the filter surface we have perhaps a built-in oxygen supply. Calculations based on the density of algal growth and on their normal rate of oxygen production indicated that if the entire slime film could be exposed to daylight or its equivalent, the total

oxygen requirement for stabilization of the organics could be met by algal photosynthesis alone.

Is it possible to open up a trickling filter so that every part of its surface may be exposed to daylight? There actually seems to be no good reason why novel surfaces arranged in perhaps an unconventional manner may not be used. It may well be that we have here a possible scheme for deriving another benefit from our algae, that is, growing them in a form for easy harvesting so that the high protein concentrations in their cellular material may be recovered with economic benefit. This possibility is envisaged also in the work of the University of California on oxidation ponds, or waste stabilization ponds, as a means of sewage treatment. I believe it is correct to say that a major deterrent to the application of the oxidation pond is the lack of an economical way of capturing and removing in concentrated form the algae suspended in the pond mass.

We may go beyond secondary benefits and consider the possibility of tertiary values that could result from the removal of nitrates and phosphates in solution by our algae. This is really an enormously interesting prospect in view of the increasing troubles being experienced all over the country with dense, highly objectionable algal blooms in our streams and lakes. The use of algae in special ponds to remove these minerals from sewage treatment plant effluents is under intensive study by Dr. Rohlich and his colleagues at the University of Wisconsin in Madison, and by others.

Recently I re-read that series of papers on activated sludge studies conducted by Theriault, Butterfield, McNamee, Ruckhoft, and others engaged in research at the station now known as the Robert A. Taft Sanitary Engineering Center. This set of papers is, incidentally, a classic of sanitary engineering. These engineers and scientists attempted to come to grips with basic questions of activated sludge treatment, addressing themselves to such fundamental questions as: What is activated sludge? How does it form? What is its function in waste treatment? Much sewage has flowed over the weir since then, and it is not necessary now to go into the spirited debates of a generation ago, debates on chemical oxidation versus bio-oxida-

tion, the significance of bioenzymatic action, the identification of slime-producing bacteria, and the general phenomenon of clarification. However, certain questions remain as stubbornly unresolved now as they were a generation ago.

One cannot but wonder what competitive advantage in the fight for life this jelly-like matrix called activated sludge confers on the organisms able to produce it. I put this question to our experts, physical chemists as well as biologists, and was assured that this slimy material is an excellent food-gathering mechanism. By processes of adsorption and absorption, nutrients are removed from the flowing waste and are brought within reach of the organism. This, I am sure, is true. But it is also, after all, a physical barrier to predators normally feeding on free-swimming bacteria. Does this film, therefore, provide a physical security to the organism as well as a more assured food supply? That the element of physical security is present is suggested by the work of many investigators. The following statement was made by Butterfield (3) in 1935: "Colpidium (a protozoan) added to a container of zooglea bacteria gave slightly better BOD removal and much clearer effluent than zooglea bacteria alone. Microscopic tests showed that the free-swimming bacteria had been eliminated."

The gelatinous matrix we also call "floc" definitely has survival value for the organisms. It protects them from their enemies while simultaneously bringing them food. In protected environments where food is plentiful, not only will the organisms survive, but they will grow fat. This is expressed in the polysaccharides composing the floc. So much is produced that, in waste treatment, we are forced to discard the great bulk of floc.

This matter of floc production and of the competitive advantages it provides recalls the discussions of about a generation ago on the physiological function of shells grown by marine animals on the ocean floor. In "Patterns of Survival" by John Hodgdon Bradley, the following is quoted from the address given in 1934 by the retiring president of the Paleontological Society. "All animals, and many plants, ingest with their water and food more calcium carbonate than they can profitably use. The problem of eliminating this surplus min-

eral material has always been most successfully solved by active living. The most energetic organisms possess light silicious or chitinous skeletons or no skeletons at all. The sluggards carry heavy shells." Competition forced the weak and lazy toward the ocean bottom where they are able no longer to cope with the involuntary accretion of calcium carbonate. "The more indolent began to grow shells."

Perhaps our friends, the slime-producing bacteria, are also indolent. This should not be surprising in view of the bountiful food supply they enjoy.

It is not really suggested that life in the slime is an easy one. The lurking predator sees to that. As a matter of fact, the predator is essential to a healthy system. Otherwise, our bacteria would grow fat, lazy, and inefficient.

Strange things sometimes happen in a treatment system, particularly when an intruder upsets the delicate balance. Last year when a maverick fungus got into the experimental activated sludge units (4), it succeeded in a very short time in exterminating a species of rotifer, minute bacteria-eating animals, important in the biological balance of the system. As a result, the stabilization process stopped dead.

It is well known that an effective biological treatment system depends on the voracity of microscopic animals. Their essential job is to keep the working microbial population fit and active. Recent discoveries suggest they play another important role by inhibiting the growth of *Sphaerotilus natans*, the so-called sewage fungus, which is associated with sludge bulking and fouls our streams. When Dr. Clarence Tarzwell was studying Lytle Creek, he found that profuse growths of this nuisance were accompanied by swarms of single-cell, microscopic animals, mostly ciliates and rhizopods (5). It appeared that the amebalike rhizopods, in particular, had keen appetite for this bacterial weed. A personal communication from Dr. H. Heukelekian of Rutgers University indicates that a rotifer with a similar function has been found.

When Butterfield was engaged in his study on the identification of organisms in the activated sludge floc, he recorded an observation which impresses me as being particularly odd. It occurred while he was trying to isolate bac-

Although many of you have seen a trickling filter in a sewage treatment plant, probably few have ever run fingers through the slime covering on the filter rock, wondering what was in it and how it could be so effective and so reliable in treating highly putrescible human wastes. This organic film is obviously a filthy, slimy mess, but it holds great interest for the biologist. Dr. Bridge Cooke, our mycologist, recently completed an intensive study of the surface of trickling filters serving Dayton, Ohio, and what emerged from his report was an entrancing picture of a jungle in microcosm (2).

The slime was virtually a reproduction of the earth surface, especially with respect to the harsh competition for survival among organisms. The fungi in the slime held tightly to the underlying rock and gave the slime its structural strength. Filamentous algae likewise gave support to the slime layer. The fungi were akin to jungle trees, and the filamentous algae akin to green foliage. Broad savannahs were represented by extensive growths of surface algae. A variety of protozoa and higher animals browsed among the diverse plant life, and still others preyed indiscriminately on microscopic forms. Feeding on everything they contacted were insect larvae, worms, and snails. Here, in the slime, as in our familiar life, it is an eternal struggle for survival. Fortunately for us, the survivors represent a well-balanced energy and material flow, assuring good waste treatment.

The presence of the algae in the slime film was especially interesting. Obviously, they were thriving. Through their photosynthesis they were producing oxygen, much of which presumably remained dissolved in the film. Could this oxygen possibly be of any use in supporting the respiration of the micro-organisms feeding on the organic wastes? Designs for Retirement

We have created an economy which forces people to give up their usual activities while many years of life yet remain. We have still to apply ingeniously and imaginatively the knowledge we now have to the creation of a way of life in which the retired continue to share in the social process.

The increasing commitment of American society to an extended period of retirement was recognized by the University of Michigan in planning its 12th Annual Conference on Aging, held June 22-24, 1959, in Ann Arbor.

With "Designs for Retirement" as its theme, the conference brought together more than 1,000 figures in gerontological thought to explore the nature and implications of individual and social factors in aging. The scope of these pertinent facets of retirement living was reflected by the five major segments in which the conference was divided: financing, health, housing, preparation, and uses.

An assessment of past experience and current research gave new insights into systems of cultural values, use of free time, services, varieties of suitable housing and living arrangements, and programs of individual preparation to give vitality, meaning, and social significance to the retirement years.

Five briefs of papers delivered at the conference follow.

Work, Income, and Housing

Improvements in medical procedures, new medications, and upgrading of nutrition here and throughout the world are enabling more men and women to live beyond their 65th birthday. Since the turn of the century, the number of people aged 65 and over has increased more than 3½ times, from 3 million to more than 14 million, while the total population barely doubled. By 1980, it is estimated the number of aged in the United States will have risen to some 25 million in an anticipated population of roughly 260 million.

Only a fraction of the aged population in the United States is institutionalized. The last complete census in 1950 showed that only 3.1 percent of the persons 65 years of age or over

Based on a paper presented by E. Everett Ashley 3d, director, Statistical Reports and Development Branch, Housing and Home Finance Agency.

teria from the gelatinous, zooglea matrix by washing it with distilled water. He reported as follows: "In carrying out this cleansing procedure, an unexpected phenomenon was encountered. During the course of the washing, the embedded bacterial cells would free themselves from the gelatinous matrix and move away with incredible speed, dispersing themselves throughout the dilution water long before a satisfactory washing had been accomplished" (3). Subsequent observations suggested that the bacteria had left the gelatinous matrix because no nutrient was being absorbed. The dispersing action was prevented by washing with water containing dissolved organic material. The interpretation of this occurrence is, in my opinion, simple. Bacteria have to feed continuously. When their food concentrating mechanism fails them, they are literally forced to leave their homes and go searching for food.

Butterfield's observation is of particular interest in the light of a recent report by Dr. Herman Amberg indicating that, in the laboratory, growth of *Sphaerotilus* could be prevented by substituting a schedule of intermittent discharges of pulp mill wastes for one of continuous discharge (6). Perhaps here too, the individual organisms composing the *Sphaerotilus* filaments were forced to leave their abode during the period of no discharge and seek their food by freely swimming about. Although I am not aware of any extensive observations on this point, the hypothesis is appealing.

We are slowly learning more of what goes on in the microworld of waste treatment. Eventually we may even be able to develop microbial systems to handle lignins and certain synthetic organics that presently pass through treatment practically unaltered in character or concentration. The success of geneticists in developing new strains of bacteria encourages use of their techniques in research. This goes much further than simply exposing the organisms to the organic chemicals, hoping they will, through hunger, learn how to use them as food. Bac-

teria can be trained. They have excellent capacity for adapting themselves, and they breed so fast that a mutant strain can quickly establish itself in the appropriate environment.

We are engaged in developing intelligent ways of getting micro-organisms to accept strange compounds as nutrients, shocking them if necessary into evolving the necessary appetite and digestive muscle to do the job efficiently. However, we have much to learn ourselves before we can, in scientific fashion, routinely mold microbial communities into smoothly functioning organizations for breaking down highly complex compounds.

Bacteria must feed on highly energized carbon and nitrogen compounds to satisfy growth and living requirements. They soon learn to relish most manmade compounds, even very complex ones. Others they reject, presumably because certain molecular structures are too hard to break up and digest. Perhaps, if research is sharp enough, we may be able to identify many of these barriers and learn how to overcome or avoid them. It is evident that we must learn more about bacterial enzyme systems, particularly how to stimulate the development of new ones.

Designs for Retirement

We have created an economy which forces people to give up their usual activities while many years of life yet remain. We have still to apply ingeniously and imaginatively the knowledge we now have to the creation of a way of life in which the retired continue to share in the social process.

The increasing commitment of American society to an extended period of retirement was recognized by the University of Michigan in planning its 12th Annual Conference on Aging, held June 22-24, 1959, in Ann Arbor.

With "Designs for Retirement" as its theme, the conference brought together more than 1,000 figures in gerontological thought to explore the nature and implications of individual and social factors in aging. The scope of these pertinent facets of retirement living was reflected by the five major segments in which the conference was divided: financing, health, housing, preparation, and uses.

An assessment of past experience and current research gave new insights into systems of cultural values, use of free time, services, varieties of suitable housing and living arrangements, and programs of individual preparation to give vitality, meaning, and social significance to the retirement years.

Five briefs of papers delivered at the conference follow.

Work, Income, and Housing

brief Improvements in medical procedures, new medications, and upgrading of nutrition here and throughout the world are enabling more men and women to live beyond their 65th birthday. Since the turn of the century, the number of people aged 65 and over has increased more than $3\frac{1}{2}$ times, from 3 million to more than 14 million, while the total population barely doubled. By 1980, it is estimated the number of aged in the United States will have risen to some 25 million in an anticipated population of roughly 260 million.

Only a fraction of the aged population in the United States is institutionalized. The last complete census in 1950 showed that only 3.1 percent of the persons 65 years of age or over

Based on a paper presented by E. Everett Ashley 3d, director, Statistical Reports and Development Branch, Housing and Home Finance Agency.

teria from the gelatinous, zooglea matrix by washing it with distilled water. He reported as follows: "In carrying out this cleansing procedure, an unexpected phenomenon was encountered. During the course of the washing, the embedded bacterial cells would free themselves from the gelatinous matrix and move away with incredible speed, dispersing themselves throughout the dilution water long before a satisfactory washing had been accomplished" (3). Subsequent observations suggested that the bacteria had left the gelatinous matrix because no nutrient was being absorbed. The dispersing action was prevented by washing with water containing dissolved organic material. The interpretation of this occurrence is, in my opinion, simple. Bacteria have to feed continuously. When their food concentrating mechanism fails them, they are literally forced to leave their homes and go searching for food.

Butterfield's observation is of particular interest in the light of a recent report by Dr. Herman Amberg indicating that, in the laboratory, growth of *Sphaerotilus* could be prevented by substituting a schedule of intermittent discharges of pulp mill wastes for one of continuous discharge (6). Perhaps here too, the individual organisms composing the *Sphaerotilus* filaments were forced to leave their abode during the period of no discharge and seek their food by freely swimming about. Although I am not aware of any extensive observations on this point, the hypothesis is appealing.

We are slowly learning more of what goes on in the microworld of waste treatment. Eventually we may even be able to develop microbial systems to handle lignins and certain synthetic organics that presently pass through treatment practically unaltered in character or concentration. The success of geneticists in developing new strains of bacteria encourages use of their techniques in research. This goes much further than simply exposing the organisms to the organic chemicals, hoping they will, through hunger, learn how to use them as food. Bac-

teria can be trained. They have excellent capacity for adapting themselves, and they breed so fast that a mutant strain can quickly establish itself in the appropriate environment.

We are engaged in developing intelligent ways of getting micro-organisms to accept strange compounds as nutrients, shocking them if necessary into evolving the necessary appetite and digestive muscle to do the job efficiently. However, we have much to learn ourselves before we can, in scientific fashion, routinely mold microbial communities into smoothly functioning organizations for breaking down highly complex compounds.

Bacteria must feed on highly energized carbon and nitrogen compounds to satisfy growth and living requirements. They soon learn to relish most manmade compounds, even very complex ones. Others they reject, presumably because certain molecular structures are too hard to break up and digest. Perhaps, if research is sharp enough, we may be able to identify many of these barriers and learn how to overcome or avoid them. 1. Complete dwelling facilities on one floor, including a bathroom, with that floor reached by few, if any, steps.

2. No thresholds or other tripping hazards.

3. Nonslip surfaces in hallways, bathrooms, and kitchens, to further minimize the danger of falling.

4. Handrails by all steps and inclines.

5. Adequate handgrips, capable of supporting a heavy person, by all bathtubs and toilets.

6. Adequate illumination of all steps and other potentially hazardous areas.

7. Fully automatic central heat, where climatic conditions require it.

Other features which might be present are:

1. At least one bedroom and elimination of any plan which includes use of the living room for sleeping.

2. Doors wide enough to permit moving about the dwelling in a wheelchair.

3. Windows easily operated and cleaned.

4. A bathroom large enough and so designed as to permit its use by a wheelchair patient.

Desirable features, although not always practical to obtain, would be:

1. Communication by any feasible system from the bathroom and bedroom either to an adjacent dwelling unit or any point where aid is available most of the time.

2. A floor plan and window design which permits sunlight to penetrate into the dwelling unit, especially during the winter months.

In addition to satisfactory design, a dwelling for an older person should be located:

1. Near adequate public transportation.

2. Adjacent to everyday shopping facilities.

3. Convenient to adequate medical and hospital facilities.

4. Free from major traffic hazards.

5. Away from sources of excessive noise, malodorous fumes, or smog.

6. Close to recreational facilities.

7. In a neighborhood free from serious urban blight or slums.

8. In familiar surroundings near the occupants' usual circle of friends.

Except for a small fraction of the elderly population which is institutionalized, most of the aged people in the United States either maintain their own living quarters or live with relatives or friends. The U.S. Bureau of the

Census in its census of housing in 1950 found that close to one-third of the people 65 years of age or older lived with relatives. Some of them still owned their own homes and had sons or daughters living with them, presumably to provide companionship and care. In a large proportion of cases, however, parents had moved in with their children and no longer had a home of their own.

The proportion of homeownership, some 68 percent, among this age group exceeds that of any other in the population. And in 1950, some 75 percent of the homes owned and occupied by persons 65 years of age and older were in satisfactory structural condition.

Federal Aid to Housing

In recent years far more emphasis is being placed on housing for older people in the United States. Since 1956 it has been possible for friends or relatives or even a corporation to make the down payment on a house being purchased by a person 60 years of age or older and have the mortgage insured by the Federal Housing Administration. In addition, when an elderly person, either because of age, physical condition, or financial position, is unable to qualify as an acceptable mortgage risk, it is permissible for a third party to become a co-signer of the mortgage. Loans up to \$22,500 may be insured and repaid in as long as 30 years. It is also now easier for older persons to trade their existing houses for units better suited to their retirement years, since many of them already are homeowners.

Amendments to the National Housing Act also make it easier for nonprofit organizations to finance the construction or rehabilitation of rental accommodations for the aging. Such an organization as sponsor of a rental housing project of eight units or more specifically designed for the use and occupancy of older people is eligible for FHA mortgage insurance at a maximum of \$9,000 per dwelling unit, this amount being increased to \$9,400 per unit for elevator-type structures if a nonprofit project. The mortgage may be as much as 100 percent of replacement cost, while a profit-motivated project may have a mortgage of as much as 90 percent. If the project involves

were living in institutions such as hospitals, nursing homes, homes for the aged, and the like. Other aged persons, while not institutionalized, are incapacitated by chronic illness. A survey conducted in August 1957 disclosed that 15 percent of the noninstitutionalized population aged 65 and over were unable physically and mentally to carry on major activities such as gainful employment, housework, or out-of-doors recreation. Another 42 percent, while still able to carry on major activities, were handicapped to some extent by chronic illness. (Recent figures published by the Public Health Service estimate 21 million persons over 55 years of age with chronic illness, of whom 9.5 million are limited in their activity and 2.7 million are unable to work.)

Employment and Pensions

The long-range trend in the proportion of workers among older persons has been downward. Between 1890 and 1910, the proportion of men 65 years of age and over in the labor force dropped from 68 percent to 42 percent, and by the end of 1958 it had dropped to only 35 percent. In contrast, the rates for older women in the labor force in the United States continue to rise slowly over the years. The ratio of women 65 years of age and older was less than 8 percent in 1890; it is now slightly more than 10 percent. Among men, an important reason for leaving the labor force is disability; among women, keeping house is the most frequent reason given for not working at a paying job. The increase in pension programs of one sort or another, coupled with mandatory retirement in many industries, is of growing importance.

Nine-tenths of the Nation's 65.4 million paid workers were covered by the basic national system of old-age, survivors, and disability insurance in June 1958. This broad coverage includes virtually all the gainfully employed. Major groups not covered by the basic program are certain government employees who have separate retirement systems and self-employed physicians, as well as some who work part-time or with low earnings.

Also in June 1958, 8.8 million, or three-fifths of all aged persons, were drawing benefits under

the OASDI program. The total number of the aged eligible for benefits (including those not receiving benefits because they had not yet retired) was 10.5 million, or four-fifths of all men and three-fifths of all women aged 65 or over.

The amount paid to workers is determined by past earnings, under a formula designed to give a higher proportion to low-paid workers than to those with high earnings. A recent change in the law established the maximum payment beginning in 1959 as \$116 per month for a worker alone and \$174 for a married couple in which the wife qualifies as a dependent.

In addition, the Federal Government makes grants to States for financial assistance to needy individuals and families. And other Federal-State public assistance programs aid the aged. For example, nearly one-half of the blind are 65 years of age or over; the majority of the disabled are in late middle life, with approximately one-third at least 60 years of age; and about one-tenth of the dependent children aided by such programs are living with a grandparent.

Nearly 2½ million people 65 years of age and over are now receiving old-age assistance, and about one-fourth of them are receiving assistance to supplement their insurance benefits.

Beyond the cited programs, at the close of 1957 about 23,000 American firms had pension plans covering approximately 16,800,000 persons, practically all of whom were also covered by the OASDI program. About \$1,100 million in benefits was paid to some 1,320,000 annuitants in 1957 under these private systems.

Housing

Adequate housing and living arrangements are important to people of all ages, but the living environment is of primary importance to the elderly, who are especially vulnerable to disturbing surroundings.

In individual dwellings as well as in group accommodations, healthful housing for older people depends largely upon design features which minimize accident hazards, permit easy care of the household, and supply proper size and space arrangements. It is recommended that a dwelling unit for the elderly contain the following:

field of aging. It is no less amenable to social science approaches than medicine. The amount of research by social scientists in this area is pitifully small, and we cannot expect rapid advances unless there are rapid changes.

To increase the amount and quality of research by practitioners dealing with the aged, the first step would be to record the situation, the decision or action taken, and the detailed results, so that others may have the benefit of this experience. However, this is only the first step. Very often there are opportunities where research consultants would prove helpful in establishing the investigative formula for giving results more general applicability, in setting up a research design which converts a projected change of procedure into a controlled experiment, or aiding with analysis. Whether simple or sophisticated, such research by practitioners could help fill gaps and lead to cumulative knowledge.

Retirement effects on the individual are often quite complex and sometimes contrary to accepted ideas. For example, the Cornell study of occupational retirement found no great increase in dejection, hopelessness, and dissatisfaction with life among workers who retired. Other factors obviously pertained. Those with more favorable preretirement attitudes were found to be better adjusted and less dejected. None of these relationships, however, were close.

Several criticisms may be made of what may be called the old-age-problems approach to investigating the effects of retirement. A high proportion of retirees face financial restraints, inadequate housing, and social isolation, but there is no uniform degree of impact. While we may generalize about the mass, the object of inquiry is the welfare of the individual, with all his contradictions, quirks, and idiosyncracies.

In the problems approach, there is also a tendency toward descriptive, as distinct from explanatory, research. We are ultimately interested in those factors which play a part in influencing psychological reactions to retirement. By focusing on factors common to many individuals, we may ignore the peculiar matrix of conditions in each particular case which produces a given reaction to retirement. An explanatory approach would, on the other hand, lead to investigating relationships between a

White House Conference

Aging, a tangle of physical, social, and economic strands, has summoned National, State, and local specialists to a series of sessions in preparation for a White House Conference in January 1961. Committee chairmen and members of the National Advisory Committee to the conference met with Secretary of Health, Education, and Welfare Arthur S. Flemming on July 30, 1959.

State workshops and institutes are developing individual responsibilities for the conference program. The National Leadership Training Institute, convened immediately following the University of Michigan's 12th Annual Conference on Aging, was such a session.

To date, 37 of the 50 States and the District of Columbia have applied for Federal grants from \$5,000 to \$15,000 to help finance preconference activities.

multiplicity of factors, such as preretirement attitude, and some criterion of the degree to which retirement adjustment is "successful."

If we are to evaluate preretirement programs, we must have some measure of effectiveness. What results do we expect in the individual if preparation for retirement is extremely successful? If it is not successful?

An individual's mental welfare may be viewed either negatively or positively. An example of a negative definition is adjustment, defined as the degree to which unfulfilled needs are absent. A person with extremely few needs or desires may lead a vegetative type of existence and yet be classified as well adjusted if these needs are satisfied. The limitations of such a measure should be kept in mind.

Positive mental health may be exemplified by such a measure as autonomy, defined as the degree to which the individual has strongly felt needs and is aware of them. This type of measurement avoids a definition in terms of absence of something and specifies that presence of something, namely strongly felt needs and awareness of them, is necessary to achieve a high rank on a scale of mental health. The well-adjusted yet vegetative personality would, consequently, rank low.

rehabilitation of an existing structure rather than new construction, the ratios apply to value rather than replacement cost. Projects can be in the form of elevator-type structures, row houses, or even separate dwelling units if they are grouped in a contiguous project and can be for both families and single persons. In most instances, there is a mortgage limitation of \$12,500,000 for any one project. To assist in the provision of nursing care facilities for the elderly, FHA is now also authorized to insure mortgages on proprietary nursing homes if they meet certain specified requirements of standards and services.

But there are still those who simply cannot afford to pay the current rental cost. For this group, it is now possible for single elderly persons of low income to be admitted to low-rent public housing projects. Authority is also given to the Public Housing Administration to assist local housing authorities in building new housing or remodeling existing low-rent public housing projects to provide accommodations specifically designed for older families.

In addition to Federal aid in housing the elderly, several of our States give assistance, notably New York and Massachusetts. And there is widespread interest from coast to coast in FHA nonprofit rental housing. As of June 30, 1959, there were 48 such active projects in 21 States, with mortgages running close to \$50 million and containing more than 5,600 units. sponsored in the main by church groups.

The Federally aided low-rent housing has also been gaining headway. As of June 30, 1959, there were either built or to be built 12,434 units specifically set aside for the elderly. In addition to these special units for the elderly, the Public Housing Administration estimates that better than 80,000 persons aged 65 or older are living in regular low-rent housing developments.

Benefits to the aged from the low-rent housing program are not, of course, limited to new units planned specifically for them. Fifty thousand families now residing in public housing projects are headed by persons 65 years of age or older, and many younger families include an aged person.

Experience has demonstrated that a satisfactory environment for older people requires more than comfortable living quarters. The need for interpersonal relationships does not abate with age, but rather, need for the security offered by close ties and companionship may actually increase as the individual grows older and is less capable of managing his own environment. There is considerable evidence to suggest that the homogeneity of the social structure in a housing development is even more important than good design and good location.

Viewing our present aged population and considering its prospective increase in the next quarter century, housing accommodations for the aging must be built at an accelerated rate to meet the need in the years ahead.

Retirement Research Strategy

brief There seems to be a general sparsity of interchange between social scientists and practitioners in today's research climate for studies of the aged in general and evaluation of preparation for retirement programs in particular. In spite of acknowledgment given the importance of reciprocity between research and application, we find a dearth of it in practice.

Major improvements would be to increase the number and quality of studies in this field both by social scientists and by practitioners. The burgeoning field of medical sociology is an example. Through recognition by some medical personnel that sociologists could contribute by investigating sociocultural factors associated with illness or with a variety of problems associated with medicine as a profession, opportunities have gradually opened for sociologists. These opportunities for research and teaching positions and for research grants and fellowships have stimulated the sociological profession to take a far more active interest in medical sociology. I see no major reason why a similar burgeoning cannot take place in the

Based on a paper presented by Bernard S. Phillips, assistant professor of sociology, University of Illinois.

working life expectancy to 43.0 years, and his outlook for retirement had increased to 6.5 years. In the year 2000, the length of the retirement period may well triple the 1900 figure.

The magnitude of the change which has taken place is shown in comparing source of income for persons 65 years of age and older even between 1950 and 1956:

<i>Source of income</i>	<i>Percent</i>	
	<i>1950</i>	<i>1956</i>
Total.....	100.0	100.0
Employment.....	30.8	27.7
Social insurance and related programs..	28.5	57.7
Public assistance.....	22.5	17.4
No money income or other sources.....	25.2	10.0

SOURCE: U.S. Bureau of the Census: Statistical Abstract of the United States, 1958, p. 269.

Government and private pension and retirement plans and personal savings undoubtedly are related to the fact that the older population is receiving a steadier and more dependable flow of income than ever previously achieved in the history of the industrial United States. This is not to say, however, that we have achieved a state, either in coverage or in the amount of benefits, which meets adequately the financial needs of older persons.

Rapid social change creates problems of adjustment for persons of all ages, but it poses much more difficult problems for older persons. Persons now 65 years of age and over have lived through profound technological and cultural changes. Technological innovations have frequently resulted in the obsolescence of the occupational skills providing prestige, psychological adjustment, and economic security for older persons.

Social adjustment may necessitate reconsideration of present pension plans, retirement provisions, discriminatory hiring and firing practices, and the design of flexible conditions of work, including hours and types of services for the older worker. Social adjustment may also require the revamping of government programs which, in the main, are based on traditions of "poor relief" and the meeting of dire need created by the depression during the thirties. Government maintenance of income flow for the aged is not based on a comprehensive study of the economic problems of old age but rather represents a combination of patchwork provi-

sions improvised under the pressure of severe depression and political unrest.

As our knowledge of old age and retirement and its problems has increased, we have become more aware of the need to reexamine much of what exists in the form of present policy and practice. We have become aware, among other things, of the need to reexamine the meaning of retirement itself, for certainly there is no clear-cut boundary line between the "retired" and nonretired older worker. And perhaps there should not be! We have used up to this point the lazy man's administrative device of adopting uniform, compulsory practices to deal with the extremely variable situation with which the older person is confronted as he nears the end of his work career.

Just as a variable cannot be explained by a constant in the realm of physics, so it is unlikely that variable needs can be met by a uniform program in the realm of gerontological social engineering. Compulsory retirement at an arbitrarily fixed age without regard for the productive capacity, personal desires, and psychological and social needs of the person is undoubtedly a major factor contributing to the difficulties of both personal and social adjustments to old age. Furthermore, it is becoming increasingly clear that this practice represents a huge and tragic waste of manpower and national production at all times, and especially in times of national emergency.

It would be patently absurd to abolish retirement systems or even compulsory retirement systems. But compulsory retirement could depend on criteria other than chronological age. This determination, from a personal, social, and economic standpoint, could be more sensibly based on the capacity and willingness of the person to be productive. The measurement of continued capacity to produce at older ages is admittedly difficult. It is a subject for intensive and expanded research if equitable and efficient determinations are to be made. But the problem is not insoluble.

Providing adequate employment for older workers who desire it will require significant changes in a number of attitudes and practices of management in hiring and firing. That discriminatory practices against the older worker exist is clear. That justification for such prac-

These are only examples of evaluative criteria for preretirement programs. Whatever concepts are chosen, it is vital that some measure or measures be used as criteria for the degree of success. It is all too easy to assume that a program is an effective one simply because, on the basis of intuitive judgment, its audience seems interested or enthusiastic. For a variety of reasons, such judgments are usually quite useless.

If serious evaluative efforts are undertaken, we should be prepared to stand by the results. It may very well be that most current preretirement programs do not result in any significant improvement in the lot of the retiree. It may be, for example, that the major determining factor in postretirement success has to do with personality traits developed throughout life, and that even an excellent program can add little more to the picture. Or it may be that the American value system, with its heavy emphasis on continuing occupational success, is such that it would be difficult for the retiree, no matter how well prepared, to counteract this climate of opinion.

Once criteria for evaluation are developed and careful measurements tested, the next step is to identify those factors associated with high scores. Preliminary research has shown, for example, that "felt age," or how old a person feels, is associated with adjustment among individuals 60 years of age and over. Those who feel middle aged rather than old seem better adjusted, and such an attitude successfully counteracts the shock of retirement, death of spouse, and chronological aging.

Further study has shown that individuals who feel old are more negative in a variety of attitudes. They believe that the aged should dress conservatively, that the friends of old people should be old, that interest in sex is undignified for an older person, that the aged should expect aches and pains, and that doctors treat the young better than the old, and thereby accept a low cultural evaluation of themselves through these negative attitudes. There is less tendency for this low evaluation by the individual who considers himself only middle aged.

What are some of the practical implications of such research? Examples can be found in

golden age clubs, residential areas, and hobbies for the aged, and the possible impact of advice on these matters given during preretirement programs. It is entirely conceivable that membership in golden age clubs hastens the identification of oneself as old, a factor which seems to be related to maladjustment. The establishment of segregated communities for the aged may provide the very best housing, medical, and recreational facilities, yet isolation from functions normal to a mixed community may serve to encourage older age identifications and thus prove deleterious. The value of hobbies depends on the degree they represent a genuine investment of the individual's interests.

More and better research is needed. But it will not come to pass unless something is done to change the present climate of research vis-à-vis research opportunities and closer relationship between practitioners and social scientists.

Economic Facts

brief

The elderly, if they do not work productively or gainfully, are often as individuals pinched for funds, and in the mass they are an economic burden to others unless they are assured of income from past savings or social benefits. We know relatively little about the factors underlying withdrawal of older persons from the labor force. There is some evidence, however, that such withdrawal is the result more of external factors than of a voluntary desire to retire. There is much evidence that many older men would prefer to work rather than to retire and that involuntary factors, particularly compulsory retirement, account for their exodus from the labor force.

The expected period of retirement for a young man of 20 more than doubled between 1900 and 1955. In 1900, a man of 20 had a life expectancy of 42.2 years, a working life expectancy of 39.4 years, and an expected period of retirement of 2.8 years. By 1955, his life expectancy had increased to 49.5 years, his

Based on a paper presented by Philip M. Hauser, professor and chairman of the department of sociology, University of Chicago.

It is the "everything else" which we must solve.

Some say there is little, if anything, to solve. It is quite true that almost any elderly person in the United States who needs health care will get it. It is true that, if he cannot pay for it, he will get it free, either by the generosity of the one who provides the care or by the organized generosity of charity. However, it is also true that many elderly people who need care that is beyond their means delay getting it or do not seek it at all because they do not want it under humiliating circumstances.

There is no way of avoiding the fact that the aged simply cannot afford to pay the cost of health care from current income at the time of illness. Only about 40 percent have some kind of prepayment against hospital costs, most of it expensive and limited in benefits. About four-fifths of the aged attempt to assume the burden of payment out of their own resources for other than hospital care. The story written by these crisp figures is a story of self-denial, anxiety, and an undermining of life savings meant for basic necessities. There is no way to measure the amount of helpless dependency behind these figures, the destructive pressures upon relatives and family resources. Figures such as these should be matters of great concern to any society that prides itself upon the independence of its people.

For we should be concerned, not just with the fact that health care is available to anyone who needs it, but equally with the conditions under which it is dispensed. Any design for retirement, in these days, must be loomed upon a framework of dignity and independence. A major reliance upon charity is dignified neither for the recipient nor for the giver. We should be concerned also with the fact that free care, or partly free care, which places the burden of expense and noblesse oblige upon the provider of service, is a drain upon the entire community. It pinches off sources of revenue which the community's health facilities must have in order to expand, to grow, and to stand ready to meet the health care needs of all. Our voluntary hospitals, for example, cannot tolerate much longer the economic drag on expansion and proper financing that is put upon

them by the load of free and part-pay care. Under the light of this important consideration, the whole question becomes no longer one of sentiment, morality, or compassion, nor even solely one of health care for the aged, but rather a question of adequate financing for the entire community's health plant and the establishment of fertile conditions for growth in health facilities that is in pace with the march of science. More graphically, to be concerned that elderly people be covered against the cost of hospital care under terms of decency and respect is at the same time to be concerned that the hospitals be not denied necessary equipment and expansion or adequately paid personnel because the books are in the red.

The answer must be composed of several elements if it is to work, if it is to meet the needs of the aged and of the provider of hospital services.

It must cover the cost of the entire package of hospital services. Only in this way can our aged be assured of access without barrier to the services they require, not simply because they are covered for all these services but also because the hospital, adequately financed and recompensed for their care, is able to furnish the services. Service benefits make the elderly patient a full-pay patient, a status that yields a harvest of therapy to his own self-esteem, his medical and psychological needs, and the economic health of the hospital. Indemnities, on the other hand, maintain him in a state of dependency as a part-pay patient and maintain the hospital as a "part-collect" agency writing its records in red ink, a condition not good for either. For the needs of both patient and hospital, it is often debatable whether or not part-pay status is any real improvement over no pay.

The service benefit approach is especially suited to the needs of the aged, whose admissions are characterized by prolonged and frequent use of the broadest possible scope of hospital services and facilities. It makes possible an approach to the question of prudent cost that works not within the realm of financial deterrents to use, but rather as a more rationalized and economic use of an even broader range of hospital services covered under prepayment. Services and practices

tices exists, in terms of productivity of the older worker, his skill, or his dependability, is not so clear. Such evidence as is available suggests, on the contrary, that the older worker who is not afflicted with definite physical impairments or chronic disorders which handicap him more than holds his own with younger workers in many types of occupations and industry. Many of the discriminatory hiring and firing practices appear to stem from superstitions rather than from economic and factual considerations. Here again there is a great need for effective research to provide a factual basis for evaluation of the productivity and the economic contribution of the older worker and to point up the specific occupations and industries in which he can be utilized most effectively.

In general there can be little doubt that we have the capacity to deal with the economic problems of old age. Our productivity and our expanding economy can unquestionably meet the demands represented by the requirements of older persons as well as those of other claimant groups. The question is not one of determining whether we can afford the maintenance of an older population, a large proportion of which can, in fact, maintain itself if given the opportunity to do so. Our problem is rather one of determining most effectively how to utilize our human as well as other resources to assure not only subsistence but the good life for all. We have in a major way succeeded in adding years to life; we are still only scratching the surface of the task of adding life to years.

Health Care

brief The problem of providing health care to the aged has been stated succinctly in the opening chapter of a recent report of the U.S. Department of Health, Education, and Welfare: "How can higher than average medical needs be financed out of lower than average financial resources?"

Based on a paper presented by Basil C. MacLean, M.D., M.P.H., president of the Blue Cross Association.

Unfortunately the question lends itself more easily to simple definition than to simple solution. Were the question directed to some uncomplicated primitive societies, it could be answered directly by a few basically human manifestations of compassion, love, generosity, and respect for age, an answer made even simpler by the few, if any, medical resources available. There are, of course, opposite human reactions by other primitive groups who discard at the side of the trail those of their number who can maintain no longer the productivity of health and youth.

For the problem is ultimately a moral one, regardless of the level of society in which it is posed. The answer to it is, for many, a valid yardstick of the worth of any society, simple or complicated. How do we treat and assess our older citizens? Do we discard them at the side of the trail or do we make the golden years a clear recognition of service performed and rewards deserved? And do the terms of that recognition afford dignity, independence, and respect for its recipients?

This is not the only great social question of our time that, when everything else is stripped away, stands revealed as a simple morality. It is useful, from time to time, to see these questions so, in order to maintain our bearings and to remind ourselves of our ultimate goal. Yet we must return again, however reluctantly, to that "everything else" which we so casually stripped away, because this is the meat of the matter in our immensely complicated world.

"Everything else" is the entire framework of our society, its traditions, laws, and customs as they have evolved and elaborated themselves. "Everything else" is usually a matter of money. Personal compassion may be expressed by a word or a gesture, but social compassion obligates people to subdue their differing definitions of the emotion and find a way to allocate the necessary funds for the compromise. It is easy enough to find a moral position on providing health care to our aged, but it is not so easy to find workable ways of making funds available and distributing these funds through the channels of communication, exchange, vested interests, and intensely differing opinions that offer themselves for use.

only by inactivity. And our economy and community standard of living will be seriously threatened by responsibility for their care.

We are past the time when we can debate whether we can afford to supply maximum rehabilitative services within our general hospital program. Rather, our question is how much longer can we afford not to. To the individual patient, it means rehabilitative services immediately following an accident or disabling illness and early restoration to the most active life consistent with his residual capacities without a long interval which permits the physi-

cal disability to progress or the patient to develop resistance toward rehabilitative efforts. To the community, restoration of every disabled person to the most useful existence possible, whether returned to a job or simply trained for maximum self-care, means a corresponding decrease in the responsibilities of the productive members of the population. To the general hospital, rehabilitative service means a more dynamic medical program, spreading through all departments and creating more interest in the diminution of long-term patient disability and an earlier release of hospital beds.

Health Manpower Outlook

The ratio of physicians to population in the United States, which has ranged between 131 and 135 per 100,000 persons for 20 years, will drop to 126 per 100,000 by 1975 unless the rate of graduating students increases substantially, according to the latest in a series of health manpower reports issued by the Public Health Service. The number of dentists per 100,000 persons in the population is expected to decline even more sharply.

Entitled "Health Manpower Source Book, Section 9: Physicians, Dentists, Nurses," the report reveals trends in the education, location, and specialization of these professional personnel.

In the academic year 1958-59, the 85 medical schools in the United States graduated 6,895 physicians. To maintain the present physician-population ratio, our medical schools would need to graduate about 10,360 students in 1975, nearly 3,000 above the 7,410 graduates currently predicted for that year.

The 47 dental schools in the United States graduated 3,083 dentists in the academic year 1957-58. Despite the addition of eight new dental schools since World War II and large increases in the number of graduates, the ratio of dentists to population remains below pre-World War II levels. To regain the current dentist-population ratio, about 2,700 more dental graduates above the number currently predicted will be needed in 1975. This calls for a 75 percent increase in the number of den-

tal students who, according to present estimates, will be graduated during that year.

According to the report, the ratio of dentists was 62 per 100,000 people in 1940 and 57 in 1958, and is expected to decline to about 50 per 100,000 in 1975. There should, however, be an increase in the ratio of professional nurses, from 268 per 100,000 population in 1958 to 284 per 100,000 in 1970.

The nurse-population ratio has increased almost fivefold in the United States since 1910. In the academic year 1957-58, the 1,145 schools of nursing in the United States enrolled about 113,000 students and graduated 30,410 nurses. Admissions to these schools are expected to increase in the next decade, and annual graduations of up to 37,000 students are predicted by 1965.

The current combined ratio of doctors of medicine and osteopathy to population is about 140 per 100,000 persons. This is expected to decline to 133 per 100,000 by 1975. To maintain the current ratio, about 11,000 graduates a year from the Nation's schools of medicine and osteopathy will be needed in 1975, an increase of slightly more than 3,000 above the number expected for that year on the basis of present estimates.

The report contains State and regional as well as national data. It was prepared by the Service's Division of Public Health Methods, in cooperation with the Divisions of Dental Resources and Nursing Resources.

appropriate to geriatric care can be developed which take the prepayment dollar a longer way. Expanded hospital outpatient services, home nursing, and nursing homes are but a few of these.

It is essential, as it is with other elements of retirement security, that the cost of such coverage be distributed, at least in part, over the working years. In short, the cost must be rationalized through the proved method of prepayment.

The pooling of risk and the distribution of cost must be done on some basis if cost of care for the aged is to be within reach. The public is moving toward a major policy decision on how to strengthen prepayment financing for aged citizens. The task can be done through the medium of proved and experienced voluntary prepayment plans if augmented by governmental resources as may be needed.

The opening question, "How can higher than average medical needs be financed out of lower than average financial resources," can only be answered by, "They cannot." They can be financed only through a pooling of the community's financial resources, a fact which is becoming increasingly apparent. The methods and media through which these resources will be organized, allocated, and dispensed are not yet fully chosen and committed, but are still evolving.

Rehabilitation

brief

A high proportion of all illness is caused by chronic diseases, and a significant majority of all hospital beds in the United States are occupied by patients suffering from strokes, arthritis, neurological disorders such as Parkinson's disease, cerebral palsy, paraplegia, and the like, civilian accidents, industrial accidents, and other chronic disabling conditions.

Based on a paper presented by Max Karl Newman, M.D., director, Detroit Institute of Physical Medicine and Rehabilitation, and director of the department of physical medicine and rehabilitation of Carmel Hall, Detroit Memorial Hospital, Sinai Hospital, and the Jewish Home for the Aged, Detroit, Mich.

To combat and control chronic diseases, and the illness and disability that result from them, the full force of modern medicine and almost the entire range of medical and specialized services, equipment, and physical facilities are needed. Until more knowledge is gained of primary prevention of chronic diseases in children, adults, and the aged, restorative or rehabilitative medicine is needed. If it were to be provided adequately in the State of Michigan alone, however, 23 rehabilitation centers distributed throughout the State, costing from \$1 to \$3 million per institution, would be required, exclusive of the salaries of personnel numbering into the hundreds.

In this obvious impossibility, the rehabilitative service can and should be located in a general hospital as is now being done at Detroit Memorial Hospital and Sinai Hospital in the city of Detroit. Advantages of location in a general hospital are ready availability of all types of medical specialists and consultants, access to both inpatient and outpatient care, lack of duplication of certain types of facilities, possible earlier referral of the patient, better dissemination of knowledge concerning rehabilitation, wider uses of the rehabilitation principle in patient care, and total medical and surgical service.

To the uninitiated, a restorative and rehabilitative medicine program uses physical and occupational therapy under the direction of a physiatrist (the specialist in the field of physical medicine and rehabilitation) on the patient with chronic disability, such as stroke, arthritis, or a surgically repaired bone not being properly used by the patient. Psychological and social services are then added and, as the patient progresses, a State agency gives vocational counseling, testing, and job training, or ways and means of functioning to the maximum capacity despite the disability are supplied.

Many of the disabled added each year to our population could benefit by restorative or rehabilitative medicine and they can be treated early in the general hospital. If this is not done, we shall be overwhelmed in the not too distant future with a backlog of infirm and disabled old and young persons, deprived of their earlier potentialities for rehabilitation. Our medical resources will have failed these people

However, diet is only one of the factors in atherosclerosis. Some others being studied singly and in combinations are sex, age, race, physical exercise, heredity, and stress. Until we learn more, it is impossible to pinpoint the one determining factor—dietary, physical, or environmental.

The current, widespread practice is to prescribe a modified diet on the theory that it will be beneficial to the patient with a certain heart disease.

Diet therapy in heart disease, except for a few treatments of established value, is constantly changing, partly because of new findings. It is important to establish the possible benefits of each discovery to patients with cardiovascular disease.

Because of the need for information and diet guides on fat selective and fat restrictive therapy, the American Heart Association and the American Medical Association are preparing such material for the use of physicians. Its purpose is to explain the current situation and what can be expected of this type of diet therapy with the knowledge that these prescribed diets will do no harm and that they may do some good.

However, the patient's adherence to the diet regimen is the final test. Diet therapy, for the most part, is a do-it-yourself project. It is the patient himself, or the person caring for him, who must understand and follow through on a diet.

One of the biggest blocks to a successful dietary regimen is the patient's lack of sufficient instructions when the diet is prescribed. If the patient is to derive the expected benefits, he must know what changes are required and how to make them accurately for each meal as long as he is on the prescribed diet.

When the physician prescribes a diet modification, it is his responsibility to initiate the patient's diet education and, as necessary, refer him to a diet counselor (nurse, dietitian, or nutritionist) for supplementary assistance. Few physicians can take the time to do more than explain the principles of the diet and give the patient standard diet references. But rarely can adequate instructions be given or learned in one quick lesson.

Counseling Services

The majority of patients on prescribed diets lack the adequate counseling services which they should have. I exclude patients who are referred periodically during treatment by their physicians to dietitians or nurses for dietary guidance, patients attending clinics where dietary counseling is an integrated patient-care service, and hospitalized and institutionalized patients. I am concerned about the patients who, for the most part, have had only one instruction session, generally at the time the diet was prescribed. These patients are living at home and working.

Regardless of age or education, the average person does not have sufficient knowledge to fulfill accurately the requirements of most diet prescriptions. He is deluged by new and strange duties and rules. Perhaps he must learn the names and meanings of such unfamiliar nutrients as fatty acids, sodium, polyunsaturated fats, and cholesterol, and how to measure them in units, exchanges, grams, or milligrams. He needs explanations and guidance as each new need arises. When these services are provided adequately, he can follow a diet correctly.

However, even with close guidance by physician and diet counselor, it is not always easy for the patient to master the many details of his diet. To persist in meticulous daily application of his new dietary regulations demands both interest and ability.

Patients are often told to "cut down," "cut out," or "go easy" on salt, starches, or fats. Many persons disregard such advice and continue on their way, unworried. Others are convinced, however, that the prescription is essential to their health. They seek any source of help. They spend time and money and often become confused and unduly worried because the physician said, "Watch your calories."

This picture is not exaggerated. Every day numerous inquiries about prescribed diets find their way to pharmacists, government agencies, librarians, Congressmen, and even to charlatans and special food stores. Requests for help range from questions about sodium restriction to the meaning of hydrogenated and unsatu-

Diet Care and Services for Patients With Cardiovascular Disease

BETH HEAP

AS INVESTIGATORS seek the causative and preventive factors in heart disease, the public is demanding information on how to apply findings in heart research to patterns of daily living. Articles, books, and radio and television programs have supplied information, and health agencies have held open meetings, particularly on the subject of obesity and cardiovascular disease, in an effort to meet this demand. Recently the American Heart Association and the National Heart Institute presented a summary entitled "A Decade of Progress Against Cardiovascular Disease" (1).

Although diet as therapy seems to be increasing in importance, especially in the prevention and control of atherosclerosis, it is only one interrelated factor in the medical care regimen.

Status of Diet Therapy

Briefly, current diet therapy in cardiovascular disease emphasizes (a) calorie restriction to achieve and maintain correct weight, (b) sodium restriction to control the edema which often accompanies congestive heart failure and to lower blood pressure in some cases of hypertension, and (c) selection and restriction of fats as a possible factor in the treatment and prevention of atherosclerosis.

Obesity, or even relatively mild overweight,

is considered a hazard to patients with heart disease, and weight reduction is generally the physician's first order for overweight cardiac patients. Physicians vary in their methods for treating obesity, but they agree as to its danger to health, especially in heart disease. Generally, they also agree that patients should continue on an adequate diet, and when specific modifications are necessary, they should be made only on the physician's recommendations.

Sodium restriction is the established diet therapy in the treatment and control of the edema accompanying congestive heart failure. Physicians prescribe diets of designated levels of sodium according to the individual patient's needs. In some cases of hypertension, sodium restriction helps to lower blood pressure.

Sodium-restricted diets are also prescribed for the prevention of edema when treatment includes the use of such medications as adrenal steroids which have sodium-retentive properties and cause excessive fluid accumulation in the tissues.

At present there is no established dietary treatment for atherosclerosis. Current studies indicate several important facts that relate dietary fat to the level of blood cholesterol. Increasing evidence points to the importance of the ratio of saturated to polyunsaturated fats in the diet in altering serum cholesterol. Metabolism studies indicate that polyunsaturated fats in the diet usually reduce the serum cholesterol and increase the cholesterol and cholic acid in the feces. Serum cholesterol concentration is a good indication of the total lipid concentration, but its true relation to coronary artery disease is still undetermined.

Miss Heap is chief nutrition consultant, Heart Disease Control Branch, Division of Special Health Services, Public Health Service. The article is based on a paper given at the Annual Health Conference of the Pennsylvania Department of Health, held at University Park, August 18, 1959.

Hospitals and Nursing Homes in the United States, 1959

LESLIE MORGAN ABBE, B.S.

This report brings up to 1959 the general review of hospital beds in the United States published in Public Health Reports, May 1955, pp. 484-491. It includes for the first time inventories and programs of skilled nursing homes under the Federal grant-in-aid (Hill-Burton) program.

IN THE YEARS since World War II good health has become popular. People generally know that the modern skills in health care have greatly improved, and that the resources for treatment and prevention are an important part of their personal needs. This awareness has led to broad public support for the major outlays needed to build hospitals, clinics, nursing homes, and rehabilitation centers. Gains in the postwar period have been impressive for some of our health resources, while losses have occurred in others. The new forms of therapy, together with changing characteristics of our population as a whole, pose new needs hardly imagined a generation ago.

This report reviews national trends and net gains in health facilities in the United States in the last 10 years and it provides a look ahead. It is based on the series of comprehensive plans for hospital and medical facilities developed by the States under title VI of the Public Health Service Act. Hospital data are now available on a comparable reporting basis for 12 years, from 1948 through 1959. Data for skilled nursing homes are available only since 1957, but such record is considered to be reasonably com-

prehensive. Inventories in these plans reflect designed capacities, rather than present bed complements. The State plans include long-range programs for additional bed needs. Another, more limited, approach to the future is also described in this paper, with specific goals for health facilities in the next decade, as developed recently by the Public Health Service.

The State plans provide data on all facilities open to civilians, with the exception of Federal hospitals of the Veterans Administration and the Public Health Service. They report all hospitals according to the four principal categories of service provided: general, mental, chronic, and tuberculosis. They also include skilled nursing homes and a variety of facilities confined entirely or principally to outpatient care, such as public health centers, diagnostic and treatment centers (both as outpatient departments of hospitals and as independent clinics), and rehabilitation centers. This report deals only with inpatient facilities.

At the beginning of January 1959, according to the State plans, the Nation had 1,322,000 hospital beds and 245,000 beds in nursing homes which provide skilled nursing care. Not all these beds, however, are acceptable for long-range planning purposes. On the basis of fire and health hazards, 168,000 hospital beds and 112,000 nursing home beds are classified as nonacceptable.

Data for each State and Territory are shown in tables 1 and 2. For easy comparison, the States are grouped by the broad socioeconomic regions of the United States. Federal beds for civilians are not included in these figures. They comprise 126,000 beds in hospitals of the

Mr. Abbe is assistant chief of the Program Evaluation and Reports Branch, Division of Hospital and Medical Facilities, Public Health Service.

rated fat. These requests make it clear that patients are interested in learning what their diets mean and how to carry them out.

Printed as well as oral instructions should always be a part of any prescribed diet. Standard diet references are a tool designed to help the patient help himself. Three sodium-restricted diet booklets (2) are the most recent patient education references. However, any diet pamphlet is standard only while on the shelf. Little attention or space can be devoted in standard guides to individual problems such as limited education, inadequate income, or lack of interest. And it is in solving these difficulties that individual counseling is of the greatest benefit.

A patient is justified in expecting adequate dietary instructions, just as he expects the services of a pharmacist for his drugs, of a nurse for his injections, and of a physical therapist for his exercises. Yet today only a small percentage of patients have the opportunity to obtain dietary counseling. The question is how can more of these services be developed.

There are several ways, but few of them have been explored, and few have been successful. Perhaps the most practical would be a cooperative community service designed to serve all patients on their physicians' referral. Such a service would assure physicians that their patients would receive sound dietary instruction supported by recommended diet guides or manuals. The patient would be better prepared to shoulder his diet therapy responsibilities, and the community would be one step higher on the ladder of improved health services.

Although there is a dearth of counseling services, recognition is growing that adequate diet education is essential for more effective diet therapy and for the development of sound nutrition practices in the general population.

Among the many diet pamphlets particularly helpful to persons who are not on prescribed diets are three basic guides. "Food for Fitness: A Daily Food Guide" is designed for all ages (3). "The Food You Eat and Heart Disease" summarizes current knowledge about diet and cardiovascular disease (4). "Food Guide for Older Folks" includes pointers on planning, buying, and preparation of food and recom-

mendations for adjustment of calories as energy and maintenance needs decrease (5).

Future Activities

For the future, I visualize nutrition education activities which will encompass the presumably healthy adult population as well as those under medical treatment. On the premise that the earlier one starts to achieve and maintain maximum nutritional health, the better the results, the development of two new nutrition education activities seems advisable.

The first is a sound nutrition course for all high school students. Its primary aim would be to teach students the relation of adequate diet to good nutritional health. Most young people, particularly boys, leave high school and soon accept family responsibilities with the scantiest understanding of this fundamental subject.

Second, I envision a community dietary counseling service available to anyone who requests nutrition information. This same service would also be available on referral by a physician to any patient on a prescribed diet. Such a service would be one more means of helping to prevent as well as to correct nutritional disorders.

A community dietary counseling service will achieve effectiveness only when it is initiated, directed, and used consistently by members of local medical societies in cooperation with other community health groups.

Veterans Administration, 6,500 beds in hospitals operated by the Public Health Service for merchant seamen and others, and about 1,200 beds in Indian hospitals.

Postwar Construction and Net Gains

During World War II and for most of the depression decade preceding the war, hospital construction was curtailed, piling up a serious backlog of need. After the war when money, men, and materials became available for peacetime development, a great upturn in hospital construction took place. This was stimulated by Federal assistance provided by the Hospital Survey and Construction Act of 1946 (now referred to, with its amendments, as title VI of

the Public Health Service Act). In this period, too, a large increase occurred in construction of new Federal hospitals for the Veterans Administration. As shown in figure 1, total hospital construction reached a peak of more than \$5 per capita in 1951, dropping to a little more than one-half this level in 1956. Thereafter, another marked upturn took place, largely as a result of increased Federal support. A further rise is predictable through 1960 on the basis of Federal funds now appropriated. Figure 1 is based on constant prices, thus discounting the marked increase in construction costs, amounting to 44 percent, which has occurred since 1947-49. In current dollars, the 1958 volume of \$1,011 million exceeded the previous alltime peak of \$947 million in 1951.

¹ Excluding Federal facilities.² As limited by title VI of the Public Health Service Act and State programing thereunder. For some types of service, some States now have beds in excess of these measures of need.³ No data reported for nursing homes for 1948-55.⁴ Preliminary report for nursing homes, from 34 States.

Source: State plans, approved under title VI of the Public Health Service Act.

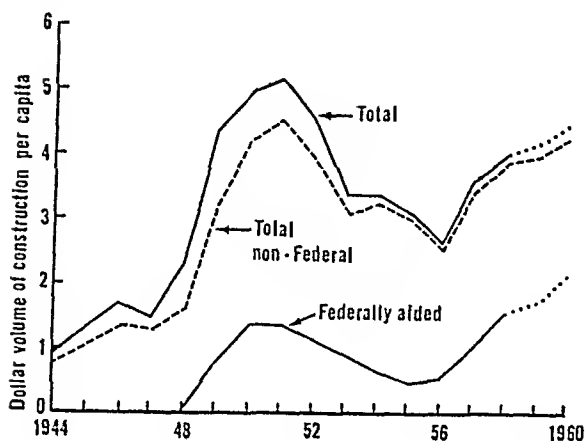

population. In this context it is useful to analyze specific levels of actual programing in each State. The additional construction definitely planned at identified sites is found, upon study, to be strongly related to the level of average income in a State, as well as to the level of acceptable beds now available.

Figure 3 shows the trend of beds now available and those programed in relation to income level for three main classes of care: short-term care in general hospitals, long-term care in chronic hospitals and nursing homes, and care in mental hospitals. The charts reflect a sum-

mary of trends found in scatter diagrams prepared from data for all the States and must not be taken as an exact pattern for all States. They show a marked tendency at all incomes for States to program at a constant level above that of the acceptable beds available, rather than to a uniform standard of need. This is particularly true for mental hospitals.

It appears that the short-term plan of most States reflects official judgment on feasible advances for the near future. This may be entirely realistic, as against arbitrary standards of long-range need. The Public Health Service

Figure 1. Value of all hospital construction in the United States and Territories, at constant prices, 1944-60

Trends in the Nation's total civilian resources for inpatient care appear in table 3, together with rates of availability per 1,000 population and of additional need, as recorded in the State plans. An expanding population and mounting obsolescence have offset new construction to a marked degree, so that from 1948 to 1959 the increase of 306,000 beds for all hospital purposes has resulted in a gain of less than 0.5 bed per 1,000 population for acceptable facilities. There are now 20,000 more nonacceptable beds in hospitals than were reported initially in 1948. Also, nearly one-half of the nursing home beds failed to meet current standards.

An elaboration of table 3 is presented in table 4 to show annual trends by type of service provided. In rates per 1,000 population, this record displays substantial progress for general hospitals, a small gain and subsequent decline in mental hospital beds, a rise and decline in tuberculosis beds, and a slow growth in chronic hospital beds. Every category has increased in the actual number of acceptable beds.

The distribution by State of the net gain in total beds available in the decade 1949-59 shows substantial variation (fig. 2). States with rapid population growth increased their total beds much more rapidly than States of little or no growth. This relation applies both to percentage increase and to the quantitative increase expressed as gain in beds per 1,000 of the population living in the State during the base year 1949. The net gain in beds per 1,000 pop-

ulation is not related to State income levels; the general trend for all States shows a gain of about 2 beds per 1,000 of the base year population at all income levels. However, percentage gains were much higher in low-income States, where the initial level of availability was low.

Local circumstances have produced occasional wide departures from the trend. Still, the broad pattern of relationship between net gains, income levels, and rate of population growth provides a new dimension of understanding and prediction. It is encouraging to find that net gains are related to population growth and that they are largely commensurate with it. Study has shown that the gains in the low-income States are predominantly the result of the Federal assistance (Hill-Burton) construction program. It must be noted that this analysis of net gains in the 1949-59 decade relates to total existing beds for all categories of hospitals. Throughout this period between 8 percent and 9 percent of these beds have been deemed obsolete and needing replacement.

Additional Needs

Basic standards of need developed in the State plans have undergone gradual changes since 1948, as shown by the data on acceptable beds and additional beds needed in table 3. From 1948 to 1959 the total need for hospital beds reported decreased from 12.8 beds per 1,000 population to 11.8. This decrease is two-thirds of the net decrease in additional need reported.

Historical data on need by single categories appear in table 4. The need for additional general hospital beds has been reduced nearly one-half, and the need for more tuberculosis beds, on a nationwide basis, reduced drastically (from 0.61 to 0.11 bed per 1,000 population) because of diminishing incidence of new cases. The States have continued to use a presumptive standard of need for mental hospitals of 5 beds per 1,000 population. According to this measure, construction of mental hospitals has not kept pace with population growth, with the result that there is a net increase in additional need of 0.17 bed per 1,000 population.

There is prospect of a long-continued backlog of needed construction, to judge by the historical trend of slow overall gain in beds per 1,000

Table 4. Trends in civilian hospital beds,¹ by type of service, United States and Territories, 1948-59

Source: State plans, approved under title VI of the Public Health Service Act.

Figure 2. Increase in total civilian hospital beds in relation to State income level and population growth, 1949-59

AMOUNT OF INCREASE
(Rate on 1949 population base)

PERCENTAGE INCREASE
(From beds in 1949)

has recently withdrawn all uniform standards of adequacy from its regulations for carrying out title VI of the Public Health Service Act, except for a minimum planning level of 2.5 beds per 1,000 population for each service area of general hospitals. Changes may therefore be expected as each State comes to identify its own formal targets of need. This new flexibility may mark a second major phase of positive planning for the Nation's health facilities, after

the early pioneering stage when statewide planning was itself an innovation and uniform standards were a valuable guide.

A Look Ahead

Prospects for the future in regard to the Nation's health plant point to a high construction expenditure during 1959 and 1960. However, because of increased construction costs (about

Table 5. Health facility program goals, 1960-70

Purpose and type	Average annual program		
	Added capacity		Estimated cost (millions)
	Rate per 1,000 pop.	Number

Population increase at 3 million per year.	7.5	22,500 beds..	405
Additional facilities for 185 million population (average).	.2	37,000 beds..	590
Replacement (facilities 50 years old).	-----	22,000 beds..	395
Modernization.....	-----	-----	100
<i>Outpatient care</i>			
Facilities for diagnosis, treatment, and rehabilitation.	-----	230 units..	70
<i>Research</i>			
At 0.5 percent of operating cost.	-----	-----	40

• Increase in research on hospital planning, operation, and use.

These goals would require construction to provide annually about 81,500 inpatient beds and 230 outpatient facilities, at a total annual cost of \$1,600 million, as shown in table 5. This annual expenditure is about \$600 million more than the amount expended in 1958 for health facility construction. It would constitute a substantial acceleration, with important shifts in emphasis to meet changing conditions. It cannot be achieved without broad understanding and support for its underlying purposes as a national investment for health as a basic resource.

Summary

At the beginning of 1959 the Nation had 1,322,000 non-Federal hospital beds and 245,000

beds in nursing homes which provide skilled nursing care, besides about 134,000 beds for civilians in Federal hospitals.

The rate of new construction is now at an alltime peak, in current dollars, but construction costs have increased by 44 percent within the last decade.

The total gain of more than 300,000 hospital beds since 1948 appears substantial, but when offset by the increase in population it amounts to only 0.5 beds per 1,000 population for acceptable facilities.

States with rapid population growth have increased the total number of hospital beds more rapidly than States of little or no growth.

Percentage gains were greatest in low-income States, where the initial level of availability was low.

Basic standards of total need for hospital beds have decreased somewhat with operating experience in State planning, but the relatively low rates of net gain in beds for hospitals and nursing homes during the past decade in relation to population to be served, indicates a long-continued backlog of needed construction.

State planning tends toward programing for specific construction at a uniform level above present level of availability, rather than upon a uniform standard of need. This may be realistic in the light of economic differentials.

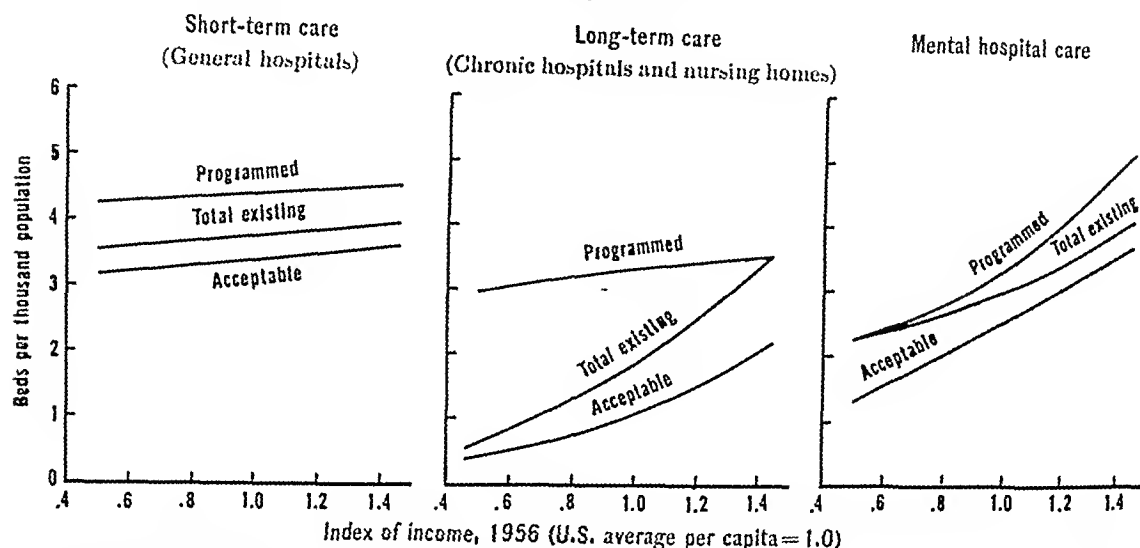

For the future, changes in emphasis to meet shifting needs and new scientific and technological discoveries are expected.

A 10-year program goal has been developed by the Public Health Service to raise the total level of inpatient beds from 7.5 beds per 1,000 population to 9.5 beds per 1,000 by 1970, with increased emphasis on mental hospitals, long-term facilities for the aged, and a modernization program. This would require an estimated expenditure of \$1,600 million annually, which is about 60 percent above the present level of construction.

Figure 3. Trend of civilian hospital beds available and programed, 1959, in relation to State income level, 1956

44 percent since 1948) much larger sums are required than in the past for comparable results. In addition, scientific and technological changes have created new services and new means of therapy requiring new kinds of facilities, while changes in the age of the population and shifts in population to large cities and their suburbs are creating new needs and maldistribution of facilities, requiring costly relocations. Other factors to be considered include the following:

1. In urban centers the hospital plants are relatively old, needing much renovation and modernization aside from actual replacement.

2. There is a new understanding of the importance of community resources for mental health care in clinics and psychiatric treatment units of the larger community hospitals.

3. The great cost of building and operating hospitals today forces attention to planning for coordination of all resources for health in the community. In particular, the long-term care of the elderly in family settings, clinics, nursing homes, and hospitals requires more attention to provide skilled services in facilities which are interrelated for common purposes.

In the light of these circumstances, which suggest substantial shifts in emphasis, the Public Health Service has recently developed national goals for health facilities during the next decade (1). These goals have guidance status only, but they reflect a concrete program (a)

with genuine net improvement on a scale appropriate to current purposes, (b) feasible to achieve within a time span which recognizes the possible impact of new discoveries in medical knowledge and therapy, and (c) reasonably possible to finance. The goals are as follows:

- Provision of sufficient new beds annually to continue the present level of 7.5 beds per 1,000 population for the annual population increase, which now exceeds 3 million persons.

- Provision of an additional 0.2 beds per 1,000 population annually in order to bring the level of all inpatient beds to 9.5 beds per 1,000 by 1970 (more than double the net advance of 0.80 beds per 1,000 population achieved in the past decade). The total gain by 1970 would be apportioned as follows:

- 0.5 beds per 1,000 for general hospital care.

- 0.5 beds per 1,000 for mental hospital care.

- 1.0 beds per 1,000 for long-term care facilities.

- Replacement of old hospital plant which becomes obsolete annually (obsolete plant being defined as that 50 years old).

- Renovation and modernization over a 10-year period (estimated at \$1 billion).

- Increase in outpatient care facilities to equal the net gain of the last decade for public health centers and diagnostic and treatment centers and a reasonable increase in rehabilitation centers.

**Table 5. Health facility program goals,
1960-70**

Purpose and type	Average annual program

Genetics and Public Health

N. C. MYRIANTHOPOULOS, Ph.D.

The epidemiological-genetic approach is ideally suited to investigations concerning the estimation of gene frequencies and mutation rates, the selective advantage of certain genotypes, the detection of heterozygous carriers, the metabolic etiology of genetic disease, and the practice of genetic counseling. Progress in any of these areas has numerous public health applications.

THE INCREASING application of human genetics in the fields of epidemiology and preventive medicine has brought about a necessary collaboration of these disciplines on a close and equal basis. Efforts to understand, control, prevent, or eradicate disease are greatly aided by the advances in genetics during the past 25 years and the growing appreciation of the human host as an important factor in the etiology of disease. The ensuing reevaluation and realinement of concepts regarding etiology are well illustrated by Shimkin (1), who, in a recent review on the etiology of cancer, writes:

"There are few, if any, simple or single causes in biology. There are, instead, complex situations and environments in which the probability of certain events is increased. The probability of the neoplastic event following exposure of an organism to a carcinogenic stimulus is modified by a large series of factors. In regard to the stimulus, among the more evident influences are those of dose, route of exposure, physical state of the material, and length and schedule of exposure. In regard to the host, the probability of the neoplastic reaction is influenced by the genetic background, age, sex, nutritional status, and intercurrent

infections. The longer the period between initial exposure and the end point of the reaction, the more opportunities occur for the introduction of additional modifying factors."

It is not too farfetched to claim that all diseases have a genetic component. Heredity, of course, does not operate in a vacuum. The environment influences its expression to a greater or lesser degree, so that it is well nigh impossible to differentiate between "purely genetic" and "purely environmental" disease. In this context the human condition appears as a continuum formed by the interaction of genetic and environmental influences. At one end of the continuum are those diseases in which the genetic factors are most powerful and the influence of the environment negligible; these are illustrated by Huntington's chorea or Tay-Sachs disease. At the other end are those diseases in which environmental factors play the chief role while genetic elements are least influential; these are exemplified by infectious diseases whose occurrence depends on the presence of the infectious agent. Between these two extremes, the genetic and environmental influences operate with varying degrees of interaction in the causation of disease.

When diseases are observed to occur in familial aggregations, it is desirable to clarify the relative roles of heredity and common exposure to some environmental stress. Neel and Schull (2) advance four criteria by which the influence of genetic factors in the etiology of disease can be detected: (a) the occurrence of the disease in definite numerical proportions among individuals related by descent; (b) failure to "spread" to nonrelated individuals; (c) onset at a characteristic age without a known precipitating cause; and (d) greater concordance in identical twins than in fraternal twins. These

Dr. Myrianthopoulos is a geneticist in the Epidemiology Branch, National Institute of Neurological Diseases and Blindness, Public Health Service.

criteria must be applied with extreme caution and critical judgment, for the pitfalls of error are many. For years, for example, because syphilitic women tended to have syphilitic babies, the disease was considered hereditary, although it is now realized that the infant is infected during gestation. Even in a disease such as tuberculosis, although predisposition may be genetically determined, the aggregation of many cases in a family is generally conceded to be a result of common exposure.

In the study of the natural history of a disease, epidemiology is, in a sense, the intelligence service of medicine. It provides information on the extent and distribution of the disease by analyzing its prevalence and incidence, mortality, age and sex distribution, geographic distribution, periodic occurrence, and association with other diseases and environmental factors. Attempts to control, prevent, and eradicate diseases depend largely on such epidemiological studies to guide the attack on the causative factors or to strengthen the host and his environment, or both.

Genetics has become an adjunct to both of these fundamental phases of public health: epidemiology and preventive medicine.

Genetics and Epidemiology

The circumstances which have brought genetics and epidemiology together result in part from increasing attention to those usually chronic diseases in which host or genetic factors appear to be relatively important. The incorporation of genetic concepts and techniques in epidemiological research has added a new dimension to medical demography: the assessment of the genetic endowments of populations.

Human genetics has developed in two areas; each stems from the same principles and laws, but operates on a different level. One, the so-called "pedigree genetics," deals with the individual case, the individual family, or a group of families, and is more directly concerned with preventive medicine. This will be discussed later. The other, "population genetics," transcends the individual case and operates at the population level. It deals with the dynamic balance between mutation and selection in relation to the inherited traits of man, that

is, with population characteristics, which are the stock-in-trade of the epidemiologist.

Following are some of the fields where the geneticist and the epidemiologist together study the natural history of genetically determined disease.

Estimation of Gene Frequencies

Knowledge of the presence of a gene which determines a disease is only a first step toward the study of its natural history. We like to know next the prevalence rate, as this is an indispensable tool for the estimation of the gene frequency by genetic theory and method. Suppose a disease determined by a pair of autosomal recessive genes has a prevalence rate of 1 per 30,000 population in the United States. Such a disease is phenylketonuria (3). According to the Hardy-Weinberg law, the gene frequency of this disease (q) is 1 in 173 and the carrier frequency ($2pq$) is 1 in 86. In other words, 1 person out of 86 in the population is a carrier of the phenylketonuria recessive gene. In England the prevalence rate of phenylketonuria is half that of the United States, 1 per 60,000 population (3). The gene frequency of this disease in England is 1 in 215, and one person out of 122 is a carrier of the recessive gene for phenylketonuria. (Actually the frequencies of phenylketonuria as estimated by Jervis in the United States and Munro in England are 1 in 25,000 and 1 in 50,000 respectively. The figures 1 in 30,000 and 1 in 60,000 presented here were derived by excluding those cases known to have consanguineous parents.)

An estimated gene frequency may not apply to the whole population for which it was estimated because the gene may be present in greater frequency among some subgroups of the population than others. The study of the frequency of thalassemia in Rochester, N.Y., is an example (4). It was found that 11 out of 100,000 children born in the city between 1928 and 1942 were affected with the disease, and from this it would appear that the frequency of the heterozygous carriers would be about 1 out of 50 persons. It so happens, however, that there is a rather large isolate of Italian descent in Rochester, and the 11 cases were of children born within this group. The estimate of the thalassemia gene, therefore, would apply only

Recent advances in research in genetics and biochemistry are described in a series of three articles, which began publication in the September 30, 1959, issue of *Scope Weekly*, as offering high hopes for public health.

In effect, the report says the studies give promise of almost unlimited uses of chemistry to correct physical deficiencies and to strengthen the genetic strain. It notes that awareness of enzymatic defects in metabolism has been coupled with methods of repairing such chemical flaws. Moreover, it cites the discovery of the principle of transduction, the transfer of genetic material from one cell to another, as suggesting possibilities of strengthening resistance to parasites, as well as enlarging the mental and physical potentials of humanity.

Basic ideas that have become apparent from such research were defined by Dr. Edward Lawrie Tatum of Rockefeller Institute, who along with Prof. George W. Beadle of the California Institute of Technology and Dr. Joshua Lederberg, then at Stanford University, was a Nobel medical laureate in 1958. Tatum listed the following concepts:

All biochemical processes in all organisms are under genic control.

These processes are resolvable into a series of individual stepwise reactions.

Each single reaction is controlled in a primary fashion by a single gene; there is a one-to-one correspondence between gene and biochemical reaction.

Therefore, the mutation of a single gene results only in an alteration in the ability of the cell to carry out a single primary chemical reaction.

"Perhaps within our lifetime," he said, "the code of life processes tied up in the structure of proteins and nucleic acids will be broken. This may permit the improvement of all living organisms by processes which we might call biological engineering."

In the same article, Dr. Laurence H. Snyder, president of the University of Hawaii, said that biochemistry and genetics offer a sound approach to diagnosis, prevention, and therapy.

He said there are "reasons for believing that genetics is involved in one way or another in the development of all disease."

to the Italian isolate. The total number of births in the isolate during the 15-year period was estimated to have been in the order of 26,000. The frequency of thalassemia in the Italian subpopulation, then, becomes 1 in about 2,400 and the frequency of the heterozygous carriers 1 in 25 persons.

Another case in point is the frequency of the recessive gene for Tay-Sachs disease which has long been suspected of occurring more frequently among Jewish than among non-Jewish people. Kozinn(5) and his associates in a recent study in the New York City area estimated that the gene frequency for Tay-Sachs disease among Jews is about 1 in 100 and the frequency of carriers about 1 in 50, while for non-Jews the gene frequency is about 1 in 660 and the frequency of carriers about 1 in 300. Another study now being conducted by the National Institute of Neurological Diseases and Blindness, Public Health Service, shows the same trend. Since the homozygote in Tay-Sachs

disease dies before reaching reproductive age, only matings between heterozygous carriers will produce affected children. The chance that two Jewish heterozygotes will marry is the product of their separate probabilities of carrying the gene, or 1 in 2,500. The chance, however, that two non-Jewish carriers will marry is only 1 in 90,000 which, admittedly, is very remote. The task of control and prevention of Tay-Sachs disease is quite different in magnitude and intensity in the two groups.

Estimation of Mutation Rates

Nature tends to maintain a balance of forces between selection and mutation. Selection against deleterious genes occurs either naturally or by eugenic practices. Mutation, however, reintroduces these deleterious genes in the population at a specific rate. It is of great importance, therefore, to know the rate at which normal genes mutate in the population if their control or elimination rate is to be ef-

fective. The tools needed here again are both epidemiological and genetic, for any attempt to arrive at an estimate of the mutation rate of a gene must stem from an accurate knowledge of the incidence rate of the disease determined by the gene in question.

Progressive muscular dystrophy of childhood may serve to illustrate the point. This type of muscular dystrophy is inherited in a sex-linked recessive manner; that is, it occurs only in males who receive the "defective" gene, located on the X (sex) chromosome, from their mothers. The mothers of affected boys act as genetic carriers but are not themselves affected because the defective gene is masked, so to speak, by the normal gene, or allele, located at the same position on the other X chromosome. (Females have two X chromosomes, while males have only one.) Thus mothers who are genetic carriers for childhood progressive muscular dystrophy pass on the gene to half of their sons, who develop the disease, and to half of their daughters, who in turn act as genetic carriers.

The onset is usually in about the third year of life and its progress is so rapid that the affected children are invalids by the time they reach 10 to 12 years of age. Few live past the age of 20 years. In spite of the fact that the gene is eliminated with the death of the affected individual before he reaches reproductive age, the frequency of the disease does not change appreciably in the population, and a rather high mutation rate would be required to maintain it at a constant level. Stephens (6) and his associates estimated the mutation rate by ascertaining the number of dystrophics born in Utah during the 10-year period 1931-41. There were 18 such cases, and 6 of these were considered as new mutations because there was good evidence that the gene had not been passed down through a line of female carriers to the affected individuals. Approximately 126,000 children were born in the State during that period. If half of them were males, then 6/63,000 gives the approximate mutation rate per X chromosome per generation. The estimate is 9.5×10^{-5} , or about 1 mutation per 10,000 male births.

The epidemiological-genetic cooperative approach during the last few years has been

instrumental in enabling us to estimate the mutation rates of the genes responsible for many diseases. Some of these estimated mutation rates in man are summarized below:

Condition produced by gene	Mutation rate per million genes per generation
Autosomal dominant:	
Epiloia	8
Chondrodystrophy	42
Pelger's nuclear anomaly.....	80
Aniridia	5
Retinoblastoma	14
Autosomal recessive¹:	
Albinism	28
Congenital total color blindness.....	28
Tay-Sachs disease	11
Ichthyosis congenita.....	11
Cystic fibrosis of the pancreas.....	700
Amyotonia congenita.....	20
Sex-linked recessive:	
Hemophilia	32
Pseudohypertrophic muscular dystrophy.....	95

¹ The general feeling among investigators currently is that mutation rate estimates for autosomal recessive genes may not be valid because of unknown heterozygote effects. If, for example, the heterozygote has a slight advantage sufficient to perpetuate a rare recessive lethal gene in the absence of mutation, then the estimate of the mutation rate would appear to be too high.

Selective Advantage of a Genotype

It has been known from experimental work in lower animals, especially in *Drosophila*, that the heterozygous condition of certain traits may have some selective advantage, that is, be reproductively superior, over either dominant or recessive homozygote. This phenomenon is known in genetic terms as "balanced polymorphism." Although it has been suspected for a long time that balanced polymorphism may operate in man, the first instance of such selective advantage in a human population was dramatically demonstrated by Allison (7) in 1954 with his work on sickle-cell anemia. This disease is genetically determined by a pair of incompletely dominant genes (genes which in the heterozygote produce detectable phenotypic effects). In the homozygous condition, the gene results in a severe, chronic hemolytic anemia which is often fatal before puberty.

In the heterozygous condition, the clinical picture is known as sickle-cell trait and results

in a variable syndrome which is compatible with survival. The gene is apparently much more frequent in Negroes than in whites. It is present in 10 percent of American Negroes, and 1 out of 500 of them is affected with sickle-cell anemia. Allison noted that in spite of the mass elimination of the recessive gene because of its lethality in the homozygous condition, its frequency was abnormally high in certain regions of Africa. This could be explained either on the basis of a high rate of mutation which would reintroduce the gene in the population or by attributing to the heterozygote some selective advantage. Indeed, Allison showed by both observation and experiment that in some regions of central Africa in which the frequency of the gene was very high, the heterozygous state afforded protection from falciparum malaria, which is endemic in those areas. Allison also observed that sickle-cell trait frequencies of 30-40 percent occur in geographically widely separated tribes in Africa and that these tribes are characteristically found in intensely malarious regions. He calculated that the reproductive fitness of the heterozygote must be 1.26 times that of the normal homozygote for an equilibrium to be maintained under these conditions.

Investigations along these lines have barely begun. It is possible that the distribution of many other genetic diseases and the gene frequencies that perpetuate them can be explained by balanced polymorphism. The question should be pursued by epidemiological-genetic methods.

Effects of Geographic Factors

It is well known and accepted as axiomatic that heredity alone is incapable of producing any character; the character in question will appear only if an optimal environment makes its expression possible. A study of environmental conditions, therefore, is essential for the complete understanding of the natural history of a genetically determined disease.

One environmental factor is geographic. Recently Mackay and Myrianthopoulos (8) presented evidence favoring genetic determination of multiple sclerosis. Although they could not postulate a mode of inheritance, they noted, after preliminary analysis of the affected sib-

lings and first cousins of their probands, that the hereditary factors involved must operate with greatly reduced penetrance. Earlier, Kurland and Westlund (9) demonstrated that multiple sclerosis was more prevalent in cold northern climates than in warm southern ones. It is possible that a correlation exists between penetrance and geographic distribution in multiple sclerosis.

Geographic isolation continues to be one of the most important factors in differential distribution of gene frequencies. On the island of Guam, for example, amyotrophic lateral sclerosis is responsible for approximately 10 percent of the deaths, while in the United States amyotrophic lateral sclerosis is estimated as the cause of death in only 0.1 percent of the population. There is good reason to believe that the majority of cases on Guam are genetically determined, while in the United States only a small proportion of cases are found to have positive family history. Whether the geographic isolation, the population size, or other environmental conditions are responsible for the high prevalence of amyotrophic lateral sclerosis on Guam, it is the natural responsibility of the epidemiological-genetic team to investigate.

Genetics and Preventive Medicine

The contributions which genetics has made to many facets of preventive medicine, especially diagnosis and treatment, are well recognized. For example, understanding of the genetics of the Rh factor by physicians and parents has aided in saving thousands of newborn babies that might have perished from erythroblastosis fetalis. Most physicians now routinely include a "family history" in the anamnesis of events of their patients' histories, and some even consider it a deciding factor in differential diagnosis.

Other possible applications of genetics to preventive medicine are not as widely appreciated. In many respects they constitute an untapped source of valuable information in the fight against disease.

Detection of Heterozygous Carriers

Heterozygous carriers, as the term is used here, means not only the carriers of recessive

genes in the heterozygous condition but also the carriers of dominant genes for diseases which have a late onset, such as Huntington's chorea or progressive muscular atrophy. The importance of being able to recognize these individuals who have the potentiality either to produce affected children or become affected themselves is self-evident.

In our search for signs or symptoms by which we would be able to identify the heterozygote, we are presently limited to the observation of recognizable morphological deviations or to the identification of detectable biochemical deviations from the normal. More often than not, these are elusive either because they are so minute as to be considered insignificant or because they occur in areas in which they are inaccessible and unsuspected. In spite of these difficulties, progress toward the recognition of the heterozygous state has been considerable for a good number of diseases. In some cases the heterozygote can be detected with 100 per cent accuracy. In others, the degree of accuracy is much less.

On the basis of our ability to recognize the heterozygous state, genetic diseases can be classified in three categories.

First are those conditions in which the heterozygous state produces a recognizable clinical picture, albeit not as severe as that produced by the homozygous conditions. In this category belong the by now classic sickle-cell anemia which in the heterozygote is manifested as a sickle-cell trait; and thalassemia major which in the heterozygote is manifested as thalassemia minor.

Second are those conditions in which the carrier state is characterized by a subclinical effect with corresponding slight phenotypic change which can be detected with appropriate known and available tests. In this category belong gout whose carrier state shows only hyperuricemia; hereditary hemolytic jaundice which in the carrier state is characterized by asymptomatic spherocytosis; xanthomatosis in which the heterozygote shows hypercholesterolemia.

Finally are those conditions for which the carrier state can be recognized in some but not in all cases. Dystrophia myotonica, Huntington's chorea, galactosemia, Friedreich's ataxia, hemophilia, and a score of other conditions be-

long in this group. For some of these the rate of the detection of the heterozygote comes close to the genetic expectation while for others the degree of accuracy is small. This is not surprising since, as previously mentioned, for most of these conditions the detection of the heterozygote probably depends on the recognition of minute or subtle biochemical deviations which presently available techniques cannot assess accurately.

Neel and Schull (2) compiled a list of diseases in which it may be possible to recognize the carrier state. They devised a grading system of 1-4 to indicate the reliability of recognition of the carrier state, grade 1 being the most reliable and grade 4 the least reliable.

Whatever information is available now, even for diseases in the less reliable grades, can be very useful, when interpreted by an experienced worker, in preventive medicine and especially in genetic counseling. With the perfection of such methods as tolerance tests and the refinement of bioassay methods, it may become possible to detect accurately the heterozygote for many genetic diseases.

Genetics and Metabolism

Modern genetics has particularly studied the ways in which genes act. There is abundant accumulated evidence that genes produce their effects through metabolic pathways. The original investigations in this field by Beadle and Tatum with the mold *Neurospora* won them the Nobel Prize for medicine in 1958. Actually, Sir Archibald Garrod can be regarded as the prodrome of biochemical genetics, for he first drew attention to what he called "inborn errors of metabolism" as far back as 1908. The inherited diseases based on metabolic abnormalities which Garrod described were: alcaptonuria, cystinuria, albinism, porphyria, and pentosuria.

Today a large number of diseases are believed to result from hereditary flaws in protein, carbohydrate, or fat metabolism. For a good number of these diseases, investigators have identified the enzymatic level where occur the metabolic blocks controlled by genes. It is easy to see the significance of such precise knowledge for now the problem can be attacked

at its roots. Two examples cited here illustrate the possibilities.

Phenylketonuria is a metabolic disorder in which, due to metabolic deficiency, there is a failure of transformation of phenylalanine to tyrosine. This block is controlled by a pair of autosomal recessive genes. The molecule whose dysfunction is responsible for this failure is a liver enzyme concerned with the oxidation of phenylalanine. The disturbance is present at birth and is characterized by elimination of phenylpyruvic acid in the urine, various neurological signs, and mental deficiency. Several attempts are now being made to treat children suffering from phenylketonuria with a special diet, free of phenylalanine. Although it is early yet for full evaluation of this treatment, encouraging results have been reported. The present status of the situation has recently been reviewed by Knox and Hsia (10).

Galactosemia, or idiopathic galactosuria, is another metabolic disorder of infants apparently dependent on a pair of recessive genes. It is the result of an inability to convert galactose, a component of milk sugar, into glycogen due to a decrease or absence of the hepatic enzyme Gal-1-P uridylyl transferase. The disease is accompanied by severe clinical symptoms such as failure to gain weight, hepatomegaly, jaundice, diarrhea, vomiting, albuminuria, and zonular cataract. When galactosemia is correctly diagnosed, it is often enough to remove galactose from the diet and the clinical manifestations, which otherwise may have serious consequences, disappear.

An opinion shared by many geneticists and biochemists is that all genetically determined diseases are metabolic in origin. If this be true, then as biochemical techniques become more refined and precise, research should be able to uncover the underlying metabolic defect not only in the affected individuals but also in the heterozygous carriers.

Genetic Counseling

Genetic counseling not only has potential importance in the prevention of genetic disease, but also helps to dispel false fears about hereditary traits. The primary function of genetic counseling is to provide people with information regarding their genetic problems.

The physician should be the person most qualified to give genetic advice. He is thoroughly versed in medical matters and also knows intimately the personalities and needs of his clients. Unfortunately, few physicians are trained to give professional advice in genetic problems. Medical schools seldom offer formal training in medical genetics. Neither do they ask for courses in general or human genetics as entrance requirements.

Some of the institutions which have given serious consideration to the teaching of human genetics and the training of scientists in this field have established genetic counseling centers where physicians can refer their patients for counseling and where genetic problems per-

taining to the individual, the family, and the community can be handled. There are about a dozen or more such centers in the United States, less than 1 per 10 million people (see list).

No two of the problems which confront the genetic counselor are the same even if they involve identical conditions. Obviously, the people who seek genetic counseling differ in each case with respect to physical and mental makeup, social and economic background, educational level, religious upbringing, and emotional content. Requests for counseling may be anticipatory, as with people contemplating marriage who know that a certain disease exists in one of the families. They would want to know what the chances are that their future children may inherit this disease. Some persons seek genetic counseling inevitably "after the fact," that is, after they have had one or more affected children. In these cases, the condition is usually recessive and the parents not affected. They find that they are genetic carriers when they have one affected child, and they are concerned about the chances of repeating their misfortune.

Many requests for counseling concern children to be placed for adoption. The adoption agency or the prospective parents want to know whether the child is a good adoptive risk, especially if it is known that there has been some undesirable trait in the child's family, such as epilepsy or mental deficiency.

The counselor's job is often complicated by situations which result from irregular action and expression of genes. Some conditions, such as peroneal muscular atrophy, show reduced penetrance; others, such as Friedreich's ataxia and retinitis pigmentosa, are inherited in more than one way; in still others, such as central nervous system malformations, the complex interaction between heredity and environment distorts the genetic ratios to such a degree that a precise evaluation of each component is impossible. The counselor has to consider all of these, and at times he has to resort to empiric risk figures in order to give effective advice. As Reed (11) put it, "It has been our lot to struggle with such complicated traits as schizophrenia, in which the heredity seems to be that of an in-

complete dominant with incomplete penetrance. This sounds too incomplete for words and the impatient soul may decide to toss out the genes altogether."

These difficulties are listed here only to show that the quality of genetic advice depends on thorough mastery of the subject matter in all its known intricate details. Genetic counseling without competent and scientific training in this field may be disastrous to the individual, defeating the whole objective of the profession.

Comment

It is evident that genetics has become an important adjunct to public health practice, teaching, and research. Even so, in some of the areas, such as the detection of the heterozygote or the understanding of the metabolic etiology of disease, the surface has barely been scratched.

The manpower needs are now acutely felt. There is a serious shortage of well-trained human and medical geneticists. In the United States and Canada hardly a dozen institutions offer adequate training in human genetics. There is need for the establishment and support of many more training institutions. There is need for the introduction of courses in human and medical genetics in our medical and public health schools. There is need for the establishment of genetic counseling centers at convenient locations to serve all the people. Only such efforts can realize the potential of genetics in contributing toward the reduction of chronic disease and improvement of public welfare.

Foster homes for New York City's aged have been provided for nearly 15 years by the New York City Department of Welfare. A few voluntary agencies also have foster home programs on a limited scale.

Foster homes meeting prescribed standards are needed for those older or handicapped individuals who require a semiprotected living arrangement but who neither desire nor need the institutional setting for congregate living.

Proprietors of foster homes in the Department of Welfare's supervised program currently receive \$100 a month for single accommodations and \$90 a month when two boarders share a room. The fee includes room, board, and personal service which may be required by the older or handicapped person.

The first patients have been admitted to New York State's research unit in narcotic addiction at Manhattan State Hospital, Ward's Island, New York City. According to Commissioner of Mental Hygiene Paul H. Hoch, the unit is the first full-time narcotics research unit in the State combining laboratory investigations and outpatient and inpatient operations. There are 55 beds for inpatients, and about 150 outpatients can be treated.

Organized for research purposes, the unit's staff will concentrate on basic investigations in an effort to determine causes of addiction and to improve treatment methods.

A wristwatch with a band too tight for the wearer was found by Dr. Howard R. Bierman to be the cause of a progressive unilateral neuritis of the thumb and index finger in an otherwise healthy woman, it was reported in the *New England Journal of Medicine*, July 30, 1959.

The art of screening for glaucoma, a combined effort of health officials and the Lions Club of Brookline, Mass., is described by John G. McCormick in *Health Educators at Work*, May 1959. From the basic planning and preparatory information campaign, through the personal courtesies provided at the clinic and evaluation, this is a lucid, blow-by-blow community case history.

By Arthur S. Flemming, Secretary of Health,
Education, and Welfare, August 26, 1959

The Federal Radiation Council

As most of you are probably aware, the President on August 14, 1959, issued an Executive order establishing the Federal Radiation Council, and along with the order the White House issued a press release which elaborated upon the order.

On August 22, the White House issued a second press release in which I had the honor of being designated by the President as the current chairman of the Federal Radiation Council. That press release also stated:

"The President also directed that the Department of Health, Education, and Welfare intensify its radiological health efforts and have primary responsibility within the executive branch for the collation, analysis, and interpretation of data on environmental radiation levels such as natural background, radiography, medical and industrial use of isotopes and X-rays, and fallout, so that the Secretary of Health, Education, and Welfare may advise the President and the general public."

The action of the President, as reflected in the three documents referred to above, constitutes, in my opinion, a constructive and effective method for dealing with the growing problems of radiological health protection.

Under the President's directive, the existing work of this Department in the radiological health field will be intensified, and the Department will undertake the additional "primary responsibility within the executive branch for the collation, analysis, and interpretation of data on environmental radiation levels . . ."

As a first step in organizing the Department for our expanding work, I have made specific delegations of responsibilities for radiological health activities. These responsibilities, which primarily concern the Public Health Service and the Food and Drug Administration, are

spelled out in the "Manual of General Program Policy—Part 10, Radiation Health," dated August 1959. This is being made a part of the Department's internal manual in which general program policy is set forth.

It should be noted that I have assigned to the Public Health Service the responsibility for "collation, analysis, and interpretation of data on environmental radiation levels as a basis for the Secretary's advice to the President and the general public."

Financial ability, of course, is always an important factor in undertaking new work. For the current fiscal year we have funds available as shown below. For comparison I have also listed the funds that were available in the preceding fiscal year.

	Fiscal year 1959 (actual)	Fiscal year 1960 (available)
Food and Drug Administration.....	\$78,500	\$100,000
Public Health Service:		
Division of Radiological Health.....	634,100	2,459,100
General research and services.....	259,000	300,000
Cancer research ¹	15,000	15,000
Total	\$1,016,600	\$3,204,100

¹ Represents costs of a special study of the effects of uranium radiation on uranium miners.

It will be noted that the 1960 funds are a substantial increase over the funds for 1959.

In addition to the funds identified in the table, the National Institutes of Health also expend funds for therapeutic and diagnostic services in the radiological field. For 1960, the funds available for this purpose total \$3,000,000.

In allocating the funds for 1960, careful consideration will be given to the new assignments given to the Department by the President. As

Chlorinated Organic Pesticide Residues in Fluid Milk

PAUL A. CLIFFORD, JONAS L. BASSEN, and PAUL A. MILLS

DURING the 4-month period August through November 1958, the Food and Drug Administration conducted a nationwide survey of antibiotic and pesticide residues in raw fluid milk in cooperation with many State, county, and municipal milk control officials.

A total of 936 raw milk samples from 16 Food and Drug Administration Districts were tested for residues of chlorinated organic pesticides. Twenty-three showed residues of 0.1 ppm or more. The findings on antibiotic residues have recently been published (1).

An earlier survey (1955) of antibiotic and pesticide residues in fluid milk by the Food and Drug Administration (2, 3) revealed that 62 percent of the 800 samples tested contained pesticide residues. The samples consisted of pasteurized milk collected at dairies in retail cartons or bottles; thus it was not possible to correlate samples which bore residues with a specific group of producers and thereby to pinpoint the source of contamination.

The results of the 1955 survey were made available to milk control officials, milk industry associations, and the Federal Extension Service of the U.S. Department of Agriculture. The Food and Drug Administration encouraged each group to conduct an educational campaign to promote the safe use of pesticides on dairy farms.

Cooperation was excellent. The four regional committees of State Extension Dairy-men, meeting with State Extension Directors and representatives of the U.S. Department of Agriculture in the spring of 1957, adopted a series of recommendations for eliminating antibiotic and pesticide residues from the milk

supply. One of the recommendations was that the Food and Drug Administration continue its surveys.

County agents were encouraged to hold meetings with dairymen. The American Butter Institute, with the assistance of the Food and Drug Administration, prepared a leaflet entitled "Safe Use of Pesticides on Dairy Farms." The leaflet received wide distribution and its message was reprinted in several national farm journals. Other milk industry associations and local national farm organizations conducted an educational campaign among their members.

In planning the present survey the Food and Drug Administration had the active cooperation of State, county, or municipal milk control officials in those areas selected as sampling stations. The Food and Drug Administration supplied the methods of analysis used in the survey for pesticide residues to interested milk control officials and dairy plant managers (4, 5).

Objectives and Plan of the Survey

This survey extended beyond the determination of the incidence and range of pesticide residues in fluid milk. A main objective was to find the source of pesticide residues in all samples containing substantial amounts of any chlorinated organic pesticide. "Substantial"

The authors are with the Food and Drug Administration, Mr. Clifford serving as assistant to the director of the Bureau of Biological and Physical Sciences, Mr. Bassen as food and drug officer in the Bureau of Program Planning and Appraisal, and Mr. Mills as chemist in the Division of Food.

soon as I know how far we can go in carrying out the President's assignments with available funds, I will give consideration to the question of requesting additional funds. It is not necessary for me to cross this bridge at the present time, because such a request cannot be adequately developed and considered until the Congress reconvenes in January.

The Department approaches its expanding role in the radiological health field with the most serious determination to carry out the President's assignment. At the same time, we are sensitive to the complexities involved in the subject, and we have the utmost respect for the labors of the pioneers, both in and out of government, who have preceded us.

Summary of a Doctoral Dissertation

LONGITUDINAL STUDIES OF TUBERCULOSIS PATIENTS REGISTERED IN HAWAII: FACTORS IN SURVIVAL RATES

Survival patterns of tuberculosis patients were investigated. The material was supplied by the history of 4,909 persons placed on the Hawaii tuberculosis case register during the period of January 1, 1947 to June 30, 1953. Various patient-cohorts were categorized by medical and demographic characteristics on registration and by mode of detection of the patient. Survival rates were computed for successive periods after registration for each cohort by methods of analysis which eliminate all competing causes of removal from the register other than death from tuberculosis. The "net" survival rate, so obtained, was used for the comparison of risks of death from tuberculosis in different patient-cohorts.

Of the total study population, 91 percent were alive 6½ years after registration. Patients whose disease was "active" on registration showed a much lower survival rate than did the "nonactive" patients. The rate of mortality from tuberculosis diminished with time after registration, particularly for the "active" patient. The significance of "activity undetermined" seemed dubious from the survival pattern. A clear time trend was noticed for

survivorship improving with year of registration, especially in "active" patients.

The survivorship differed by certain medical and demographic factors. In general, the variation was relatively large in "active" patients but it was relatively slight in "nonactive" patients. The survival rate varied more strongly by bacteriological finding than by clinical sign of activity status of the disease. The mortality was greatest for far advanced active patients.

Survivorship was relatively low for the first five years of life, rose to a maximum at the 15-24 age group, and then decreased with age. Little difference in survival by sex was noticed within specific age groups. The mortality peak observable with the group of adolescents and young adults in the general population, especially in the developing countries, may be due to excessive exposure rather than lowered resistance. Survivorship varied considerably by race.

Patients detected by minifilm surveys had more favorable survival rates than those first diagnosed because of "symptoms."—CHAI BIN PARK, M.D., M.P.H., Ph.D., *University of California, 1959.*

tial residues by paper chromatography, 17 were also analyzed by the appropriate quantitative method. Four of the 17 samples showed no residues. Obviously, these samples can only indicate the extent of false positive results by chromatography whereas we are also concerned with false negatives. A number of districts analyzed some negative phase A and B samples by both paper chromatography and by quantitative methods. Of the 49 samples, there were no false negative results, that is, cases in which the quantitative method revealed substantial residues and paper chromatography did not.

Results

Of a total of 936 phase A samples, 23, or 2.5 percent, contained substantial amounts of residue (an estimated 0.1 ppm or more). DDT, DDE, and DDD were most commonly found. Toxaphene, chlordane, and BHC were encountered less frequently. The results for each district for the 4-month period are given in table 1. No trend was noted toward a higher incidence of samples with substantial residues during any particular month.

During October and November, each district submitted 10 duplicate samples to the Food and Drug Administration's Division of Food for check analysis. These were analyzed by paper chromatography and by fly bioassay. Table 2 summarizes the results by the two methods. By paper chromatography, the Division of Food found substantial residues in 5 of 168 samples (3.0 percent). This figure compares well with that found by the districts. DDT and DDE, DDD, dieldrin, chlordane, BHC, and lindane were found in that order. Indications of aldrin and of heptachlor or its epoxide or both were noted in a few cases. The florasil column eluates of 67 percent of the samples produced no symptoms in flies. Fifteen percent of these eluates caused mortality of more than 10 percent (more than 10 of 100 flies). The MgO column eluates caused no symptoms in 46 percent of the cases and mortality of more than 10 percent in 39 percent of the cases. The higher mortality for the MgO eluates may be due to minute traces of dieldrin, aldrin, or heptachlor epoxide; flies are especially sensitive to these pesticides.

Ten districts found one or more phase A

Table 1. Results on phase A samples examined by Food and Drug Administration Districts

amounts, for this survey, were fixed at 0.1 ppm or more of pesticide residues. We were also anxious to test the value of another chemical screening procedure, namely, paper chromatography, as a control method for the average laboratory. We hoped to detect any seasonal differences in the occurrence of pesticide residues by conducting the survey over a 4-month period; thus from August through November there would be a change in the cow's diet from predominantly pasture to bulk and solid feeds. By including all 16 Food and Drug Administration Districts in the survey, the results might reveal differences in the incidence of pesticide residues in various parts of the United States.

Each Food and Drug Administration District, with the assistance of State and local milk control officials, selected one city in its territory in which to conduct the survey. The cities surveyed and the headquarters of the Food and Drug Administration District in which they are located were: Atlanta, Ga. (Atlanta); Washington, D.C. (Baltimore); Providence, R.I. (Boston); Buffalo, N.Y. (Buffalo); Chicago, Ill. (Chicago); Cincinnati, Ohio (Cincinnati); Denver, Colo. (Denver); Wichita, Kans. (Kansas City); Minneapolis, Minn. (Minneapolis); Los Angeles, Calif. (Los Angeles); New Orleans, La. (New Orleans); Metropolitan New York City (New York); Trenton and Camden, N.J. (Philadelphia); St. Louis, Mo. (St. Louis); San Francisco, Calif. (San Francisco); Seattle, Wash. (Seattle).

In each of these cities, three dairy plants were selected as monthly sampling stations. Thus, 48 sampling stations were included in the survey. Criteria used in selection were (a) an interest and desire on the part of management to cooperate in the survey; (b) a minimum of five milk pickup routes; and (c) feasibility of identifying each producer on each pickup route.

The survey was divided into three phases; phase A, the collection of fluid milk samples from bulk farm tank trucks (a few samples were composites from can routes) at each dairy; phase B, the collection of milk samples from individual producers from the pickup route found to contain "substantial" pesticide residues; and phase C, a visit to the farm pro-

ducer whose milk collected under phase B contained "substantial" residues.

Under phase A, starting in August, 1-quart samples of milk from five milk pickup routes were collected monthly at each dairy. In subsequent months, five additional routes were to be sampled, so that over the 4-month survey period all or nearly all routes were sampled at least once. Among the selected dairy plants the number of routes varied from 5 with an average of 8 producers to 54 with an average of 20 producers. Thus, more intensive testing of the milk supply was possible at those plants with a small number of milk routes. For example, one dairy plant in San Francisco had only five routes and each route was resampled every month for 100 percent coverage of the milk supply. On the other hand, at a dairy plant in Cincinnati with 54 routes, only 20 routes were sampled during the survey period.

Analytical Methods

The samples were initially analyzed by paper chromatography (4,5) for residues of DDT, DDE, DDD, lindane, BHC, dieldrin, chlordane, methoxychlor, toxaphene, and heptachlor. Samples with substantial residues, that is, an estimated 0.1 ppm or more, were analyzed by more exact quantitative methods. Where available, official quantitative methods of the Association of Official Agricultural Chemists were used. Paper chromatography gives only semiquantitative results which are not directly comparable with the results obtained by specific quantitative methods.

Successful application of paper chromatography to milk fat demands a rigorous sample "cleanup" which involves the isolation of microgram quantities of pesticide from all but traces of fatty residues. The cleanup requires steps in which losses of pesticide are almost certainly bound to occur, namely, the acetonitrile partition, the chromatography through adsorbent columns, and the evaporation of the relatively large volumes of solvents.

Thus, the usefulness of paper chromatography as a screening procedure depends on the probability of not missing samples containing substantial residues. Of the 23 phase A samples found by the districts to contain substan-

ed that a commercial exterminator had sprayed this farmer's barn. The inspector visited the exterminator and found that he had sprayed a number of barns in the area with a 0.5 percent DDT solution. He acknowledged knowing that use of DDT around dairy barns was prohibited but finally admitted that he had used DDT because it was cheaper than some of the pesticides approved for use in dairy barns. Among the producers whose barns were sprayed by this exterminator, the inspector found the name of the first producer he had visited.

The New Orleans District investigated one producer under phase C. None of the feed materials—whole corn, wheat shorts, and cottonseed meal—contained pesticide residues although the milk contained 0.06 ppm DDT. A tentative explanation was contamination of pasture with DDT from an unknown source.

The San Francisco District found two producers' milk on one bulk tank route to contain substantial residues of DDT and DDD. Joint inspections were undertaken in December 1958 by the Food and Drug Administration, California Bureau of Dairy Inspection Services, and the fieldman of the dairy bottling plant which received this milk. At one producer's, no substantial residues were found in the milk. The second producer's milk contained 6.3 ppm DDT (8.0 ppm calculated as DDD). Subsequent samples of milk and corn silage from this producer, analyzed by the State Bureau of Dairy

Inspection, revealed 4.8 ppm DDT in the milk and 12 ppm DDT in the silage. The State Bureau of Dairy Services suspended this producer from shipping milk. After this producer's milk was eliminated, a retest of the bulk tank route revealed only trace amounts of DDT. Contaminated corn silage grown on the producer's farm was the source of the pesticide residue in the milk.

The milk of the producer on the second route investigated by San Francisco District in February 1959 contained 2.0 ppm DDT. A sample of alfalfa hay being fed to the herd did not contain detectable residues of DDT. The inspection did not reveal the source of pesticide residue in this producer's milk supply.

Discussion

Although it is difficult to compare the findings in this survey with those in the 1955 survey because more sensitive procedures have since been devised, it is quite clear that there has been a definite improvement in the milk residue picture. As in the 1955 survey, DDT was the most notorious offender in the current survey. Where the sensitive bioassay procedure was employed in essentially the same manner in both surveys (florasil column, table 2) 33 percent of the 1958 samples gave a positive test (which includes trace amounts) for chlorinated organic pesticide residues, as compared with 62 percent in the 1955 survey. Moreover, in the 1955 survey the samples consisted of market milk pasteurized and ready for the consumer; in other words, they represented the mixed output of many individual producers.

In the 1958 survey the primary purpose was to pinpoint the source of contamination. The samples were drawn from bulk tank trucks in which was mixed the raw milk output of only a few producers, generally less than a dozen. Thus, in the 1958 survey one might have expected a higher incidence of very excessive residues, but we did not find this.

Summary

In a 1958 survey conducted by the Food and Drug Administration, 936 samples of raw milk

² Percentages not computed because of insufficiency of data.

samples to contain substantial residues. Nine of these districts proceeded to collect phase B followup samples. In table 3 are given the number of phase B samples collected by each of these districts and the results. Some of the negative results on the phase B samples may be attributed to a transient contamination with pesticide residues or to a delay in followup.

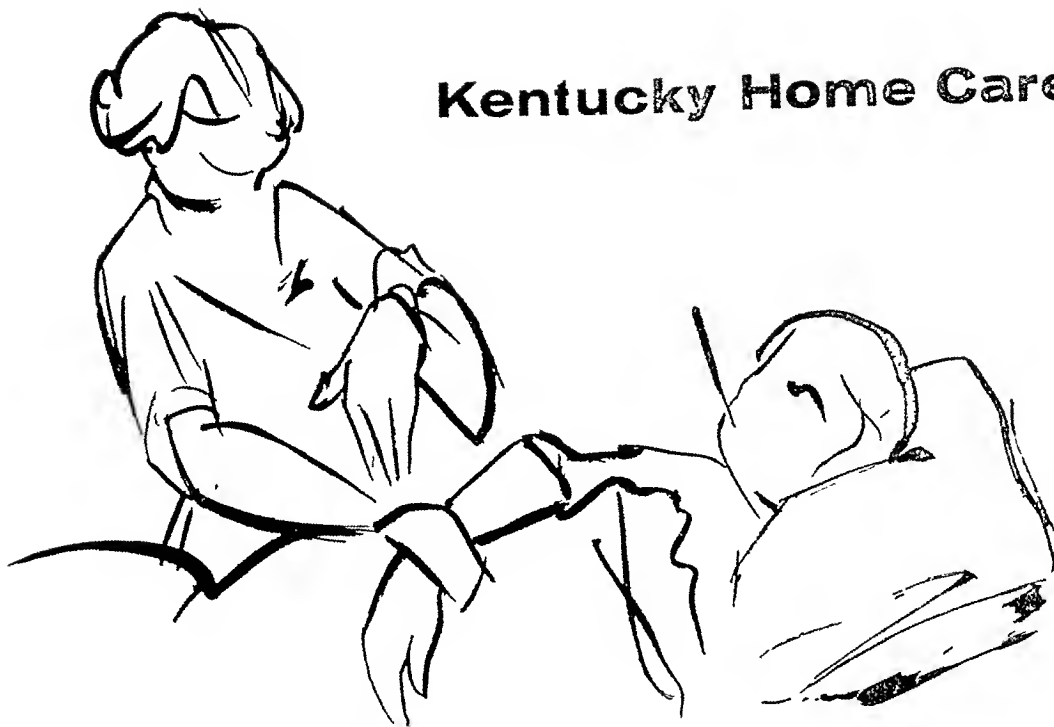

The eight producers whose milk was found to contain substantial residues in phase B were visited by Food and Drug Administration inspectors, usually accompanied by a State or local milk inspector, under phase C of the survey. The producers were questioned about their spraying practices around and in the barn, type and source of feed, and other likely sources of contamination. Samples of milk in all cases, and feed materials where indicated, were collected and analyzed for pesticide residues.

The Baltimore District investigated two producers in January 1959. Milk samples from these farms were negative for pesticide resi-

dues. The cows on both farms were fed a similar diet consisting of mixed dairy feed, clover or alfalfa hay or both, and grass or alfalfa silage. On one farm only one item, clover hay, was found to contain traces of DDT. On the other farm, alfalfa hay and alfalfa silage contained traces of toxaphene.

The Kansas City District investigated two producers under phase C. These producers were delivering milk to two different dairies. Followup at one farm revealed no detectable pesticide residues in any of the samples of hay, grain, and silage being fed. The sample of milk collected at the farm contained 0.03 ppm DDT. The source of the DDT in this producer's milk might have remained a mystery except for the investigation of the second producer. At the latter farm, samples of milk, hay, mixed grain, and silage were collected. The mixed grain, of intrastate origin, contained 0.32 ppm DDT and the milk, 0.3 ppm DDT. On questioning this farmer, the inspector learn-

Kentucky Home Care

Sadieville, Ky.

Dear Doctor _____:

I want to express to you my sincerest appreciation for the work done by the health department in helping old people.

My mother Mrs. _____ aged 87 requested that her last days be spent at home rather than in a hospital. This request would have been impossible to grant had it not been for the untiring efforts of your health nurses.

Especially am I indebted to Mrs. _____. Mother anxiously awaited her visit each day. She always brought along a ray of sunshine with her. Towards the last, when mother was so ill, she worked fervently trying to ease her and make her more comfortable. She showed me many things that made the nursing job easier.

I think this home visitation by the nurses is the most wonderful thing that has happened for the physical welfare of the aged.

Again, may I congratulate you and your staff for the wonderful work which you are doing.

Best regards,

Mrs. _____

THIS LETTER and others like it put into words the public's warm, spontaneous response to Kentucky's home care program, which was set in motion January 1, 1958, by the State health department.

Cooperation the Keynote

Working closely with county medical societies and health agencies, the division of chronic diseases of the Kentucky State Department of Health spearheads and broadens the home care program throughout the State. This is done with the assistance of the department's divisions of health education, public health nursing, and nutrition.

The home care program is more than home nursing. It includes nutrition, physical therapy, and psychiatric and community services. Yet it remains essentially a simple type of service for chronically ill patients needing medical supervision but not hospitalization; those needing continuing medical care, instruction in self-administration of drugs, or special diets; and those who might benefit from home physiotherapy. Services also extend to patients in

from 48 dairies in 16 metropolitan areas in all sections of the United States were analyzed by the 16 Food and Drug Administration's Districts for residues of chlorinated organic pesticides by a paper chromatographic method. The survey was conducted over a 4-month period starting in August. Twenty-three samples (2.5 percent) showed residues of 0.1 ppm or more. Of the 936 samples, 168 were further examined by the Food and Drug Administration's Division of Food. By paper chromatography, five of these, or 3.0 percent, showed significant residues.

These 168 samples were also analyzed in the Division of Food by a fly bioassay procedure. Depending upon the cleanup technique employed, toxic reactions were noted in 33 percent of the samples (florisil column) and in 54 percent of the samples (MgO column). Significant mortalities (taken as more than 10 percent of 100 flies) were 15.5 and 39.3 percent, respectively. The difference in incidence between the chromatographic and bioassay methods is due to the fact that the bioassay reflects the sum of all residues toxic to the housefly. Also, flies are extremely sensitive to certain pesticides (lindane, heptachlor or its epoxide, dieldrin, and others) and a few hundredths of a ppm of these might not register on the paper chromatogram. Comparable figures for the previous and the present survey are: 67 percent positive reactions in 1955 and 33 percent in 1958.

Investigations to determine the source of pesticide residues were limited to eight producers

whose milk was found to contain "substantial" residues. Of these, the source of contamination was definitely accounted for in only three cases. Feeding of DDT-contaminated corn silage (1.2 to 12 ppm DDT) was responsible for high residues, 4.8 and 6.33 ppm DDT, in one producer's milk. The contamination of the milk of the other two producers was traced to the careless spraying of barns with a concentrated DDT solution by a commercial exterminator.

The survey did not reveal any seasonal monthly differences in the occurrence of pesticide residues.

The survey showed that paper chromatography is a useful procedure in detecting substantial residues of organic chloride pesticides in fluid milk.

Deaths From Septicemia

Septicemia and pyemia caused 1,633 deaths in 1958. Of these, 353 were staphylococcal, 64 streptococcal, and 30 pneumococcal. Other agents were specified for 90 of the deaths and 1,126 were unspecified. The increase in all deaths from septicemia and pyemia over the previous year was about 23 percent, and for staphylococcal septicemia it was about 63 percent. The number of deaths from sepsis among the newborn (infants under 1 month) was 1,055, an increase of about 27 percent over 1957. Deaths from septicemia during the period 1949 through 1957 were reported in *Public Health Reports*, April 1959, p. 354.

THIS LETTER and others like it put into words the public's warm, spontaneous response to Kentucky's home care program, which was set in motion January 1, 1958, by the State health department.

Cooperation the Keynote

Working closely with county medical societies and health agencies, the division of chronic diseases of the Kentucky State Department of Health spearheads and broadens the home care program throughout the State. This is done with the assistance of the department's divisions of health education, public health nursing, and nutrition.

The home care program is more than home nursing. It includes nutrition, physical therapy, and psychiatric and community services. Yet it remains essentially a simple type of service for chronically ill patients needing medical supervision but not hospitalization; those needing continuing medical care, instruction in self-administration of drugs, or special diets; and those who might benefit from home physiotherapy. Services also extend to patients in

nursing homes without a registered nurse on the staff.

In the five-county area selected for the program's demonstration, an additional nurse has been added to each county nursing staff. All the staff nurses have been trained further by the Louisville Visiting Nurse Association and the Rehabilitation Clinic of the Louisville General Hospital, and a nutritionist, physical therapist, and social worker have been made available by the State health department.

Physician and Nurse Liaison

Home care patients first enter the program on recommendation of the attending physician, who prescribes a specific regimen of care for the nurse. After the visit, the nurse reports back to the physician. The conditions found most frequently among home care patients are cancer, heart disease, hypertension, and rheumatic fever.

Public enthusiasm for the home care program

has brought the opportunity for group activities for the chronically ill and aged in one county, through a Senior Citizens Health Club.

To health agencies contemplating home care programs, the Kentucky State Department of Health offers these guidelines:

If you are waiting for more money, remember, there will never be enough. If there isn't adequate staff, let us use what we have. Leadership? Why not supply your own?

The people, the taxpayers know what they want. When they get services that they want they will support them. There is a lot of evidence that the people want tangible services—not just advice. Where tangible services are provided, the public supports the health department. It's just common sense.

To obtain more information about the Kentucky program of rural home care, write to Russell E. Teague, M.D., Secretary, Kentucky State Department of Health, Louisville, Ky., for a copy of the Bulletin of March-April 1959.

Cutler on Special Assignment

Dr. John C. Cutler, Assistant Surgeon General for Program, Public Health Service, has been assigned to the Allegheny County (Pa.) Health Department to direct that agency's central district.

The assignment was requested by the health directors of both the State and county, primarily to help materialize their plans for a local health demonstration unit which may serve as a model for other areas. Dr. Cutler has also joined the faculty of the University of Pittsburgh Graduate School of Public Health.

Prior to his current post, which he has held since July 1958, Dr. Cutler was assistant director of the National Institute of Allergy and Infectious Diseases, Public Health Service. After his appointment to the Commissioned Corps in 1942, he held a number of research,

instructional, and administrative posts in this country and abroad. He conducted venereal disease research at the Service's research laboratory at Staten Island before continuing his research and control work in this field overseas. In 1948 he received from the Guatemalan Government the Order of Merit for his work during an assignment to the Pan American Health Organization. He also organized a public health demonstration and training program in India for the World Health Organization in 1949-50.

Dr. Cutler is a diplomate of the American Board of Preventive Medicine and Public Health, a fellow of the American Public Health Association, counselor for the International Union Against Venereal Disease and Treponematoses, and director of the District of Columbia Social Hygiene Society.

A careful review of one county's hospital records contributes to the limited knowledge of the pattern of fetal and early neonatal loss and provides information about the adequacy of registration and the medical use of terminology.

Fetal and Early Neonatal Deaths in Onondaga County, New York

EDWARD R. SCHLESINGER, M.D., M.P.H., RUTH K. BEECROFT, M.D., M.P.H.,
HILDA F. SILVERMAN, B.S., and NORMAN C. ALLAWAY, M.Sc.

IN COMPARISON with infant and later mortality, relatively little is known about the incidence of fetal mortality, especially deaths occurring during the early months of gestation. Most information on fetal mortality relates to deaths occurring after 20 weeks of gestation. There are many reports on fetal mortality in individual hospitals, but these have the major drawback of possible selection of patients unrepresentative of the population as a whole. In a few areas, such as in New York City, reporting of fetal deaths at any stage of gestation is required. Since the responsibility for reporting fetal deaths in such an area rests mainly with the hospitals, the extent of possible under-reporting is difficult to ascertain.

Dr. Schlesinger is associate director of medical services, New York State Department of Health, Albany. Dr. Beecroft is regional medical director for the Children's Bureau, Department of Health, Education, and Welfare, Region II, New York City. The late Mrs. Silverman, biostatistician with the New York State Department of Health, supervised the field aspects of the study. Mr. Allaway is associate biostatistician with the department.

As one attempt to make up for these deficiencies, information has been obtained on fetal mortality covering an entire geographic area—Onondaga County, N.Y.—from a direct study of original hospital records. Although this method includes only fetal deaths requiring hospitalization of the mother, it does obviate the factor of selection of patients present in studies in individual hospitals. Furthermore, it permits comparison with data for New York City, where all but a negligible number of the fetal death reports emanate from hospitals.

The primary objective of the study was to obtain as complete a picture as possible, from a review of hospital records, of the incidence of fetal losses occurring in 1951 and 1952 among residents of Onondaga County who were hospitalized in the county. Neonatal deaths occurring during the first 24 hours after birth in the same years were included also because of the possible difficulty in distinguishing fetal deaths occurring immediately before or during birth from neonatal deaths occurring immediately after birth. A secondary objective was the exploration of such questions as the accuracy of the period of gestation reported on the still-birth certificate and the completeness of re-

porting of stillbirths (or fetal deaths occurring after a gestation period of 20 or more weeks, as defined for purposes of reporting in New York State) as compared with information from the hospital records.

Method

Onondaga County was selected for the study for several reasons. Its population, 342,000 at the time of the 1950 census, provided a large enough base for the development of significant rates. More than half the county's population was concentrated in Syracuse, the county seat and only city, which also was its trade center and center for medical and hospital care. Furthermore, all the hospitals in the county were located in Syracuse, and all but about 0.5 percent of the recorded births in the county occurred in these hospitals. Only 5 percent of the births to Onondaga County residents were recorded outside the county.

Local facilities and the possibilities of local cooperation were even more important determinants in the selection of Onondaga County. The performance of many studies in problems relating to fetal and neonatal mortality by the Syracuse City Department of Health and by the departments of obstetrics and pediatrics at the Upstate Medical Center of the University of the State of New York, in Syracuse, tended to assure a receptive attitude on the part of the hospital authorities. The location of a medical school in Syracuse made it feasible to obtain students for a review of hospital records during the summer months between their third and fourth years of medical school.

Four medical students were assigned to the study with the aim of locating as many as possible of the hospital records of fetal and early neonatal deaths in 1951 and 1952. Cases were included in the study if the delivery occurred in a hospital or if the mother was hospitalized within 2 weeks after the event. Each medical student was assigned to one or more hospitals, where he reviewed the records and tabulated the information on schedules designed for the purpose.

A search was first conducted of the diagnostic files of the hospital, using a special guide based on the Standard Nomenclature of Dis-

eases and Operations (1). The hospital discharge diagnosis file was the principal source of cases. This file was supplemented by referral to the doctor's diagnosis card and any other available official hospital files of neonatal deaths, fetal deaths, and operations. Other supplemental sources, when available, included the pathology laboratory file of diagnoses on surgical specimens and autopsies, including those obtained from dilatation and curettage; obstetrics and gynecologic service admitting books; any special files compiled for use of obstetrics and gynecology staff; and information from specific studies.

Review of a patient's chart included examination of the physicians' and nurses' notes, especially at the time of admission and in the delivery or operating room. Each chart was searched also for pathology laboratory reports, special attention being given to reports of microscopic specimens for findings of decidual tissue or other evidence of pregnancy. No cases were included in the study purely on the basis of a history of a pregnancy which terminated previous to 2 weeks before hospital admission. The length of gestation in weeks was calculated directly from information obtained from hospital records.

The decision as to whether any case should be recorded as a fetal death or an early neonatal death depended on information pertaining to evidence of life on the hospital records. Each fetal death was recorded, in accordance with the recommendation of the World Health Organization, as early (less than 20 completed weeks of gestation), intermediate (20 completed weeks

Table 1. Fetal and early neonatal mortality, Onondaga County, N.Y., 1951-52

Mortality index	1951	1952	1951-52

¹ Percent of fetal deaths.

² Within 24 hours after birth.

of gestation but less than 28), late (28 completed weeks of gestation and over), or period of death not stated for a death that could not reasonably be classified. The physician's statement of the outcome (abortion, miscarriage, stillbirth, neonatal death, or not stated) was also recorded. Stillbirth and live birth certificates were reviewed, and the reported length of gestation was noted.

For residents of Syracuse the census tract in which the family resided was established, and mortality rates were related to the socioeconomic status of the tracts. Socioeconomic status was determined by using an index developed by Willie (2). This index is based on average monthly rental, market value of owned homes, proportion of detached single-family dwellings, median school years completed by adults 25 years of age or older, and the proportion of operatives, service workers, and laborers reported in the 1950 U.S. census. Six groups of census tracts were constituted, and were designated on a scale from I (high) to VI (low).

Results

The fetal and early neonatal death rates for each of the study years are given in table 1. For comparison with other areas, in which the ratio of fetal deaths to live births is used, rather than the ratio of fetal deaths to the total of live births and fetal deaths, the fetal death ratios are also given.

The number of fetal and neonatal deaths and the proportion of fetal deaths according to length of gestation, by the World Health Organization classification, are given in table 2. Sixty-eight percent of the 1,456 fetal deaths were classified as early, contrasted with 8.4 percent in the intermediate group and 14.8 percent in the late group; 9.1 percent could not be readily classified because of lack of information in the hospital records.

The only study which we have found to lend itself readily to comparison with the Onondaga County experience is one reported by Erhardt relating to New York City data for 1950 (3). As indicated previously, the New York City figures are based on reports submitted to the city department of health, rather than from a direct study of the hospital records. The type of material provided by the two studies is comparable, however, since the reports received in New York City emanate almost entirely from hospitals.

The proportions of classifiable fetal deaths in the early, intermediate, and late groups were very similar in the Onondaga County and New York City studies (table 3). The only marked

30-34-----	90.7	11.3
35-39-----	130.7	20.6
40 or over-----	184.8	23.3

¹ Fetal deaths per 1,000 live births and fetal deaths.

² Deaths within 24 hours after birth per 1,000 live births.

differences in distribution of fetal deaths occurred in the breakdown of early fetal deaths by 4-week periods. The proportion of fetal deaths in the 4- to 7-week and the 8- to 11-week groups is higher in New York City. These differences were balanced by a higher proportion of deaths between 12 and 20 weeks of gestation in Onondaga County. Whether these differences are real or due simply to errors in reporting cannot be determined. If the latter, it would mean that there is a tendency for hospitals to report fetal deaths occurring before the 20th week of gestation as having a shorter gestation period than is actually the case, since the Onondaga County data are based on direct calculation of the length of gestation from data in the hospital records.

Table 5. Fetal and early neonatal death rates by socioeconomic status of census tract of family residence, Syracuse, N.Y., 1951-52

Socioeconomic status ¹	Number of census tracts	Fetal death rate ²	Early neonatal death rate ³
I-----	3	88.7	3.7
II-----	6	99.9	9.8
III-----	10	79.7	10.0
IV-----	11	92.6	10.0
V-----	12	93.6	13.6
VI-----	17	97.3	16.1

¹ I is highest, VI is lowest.

² Fetal deaths per 1,000 live births and fetal deaths.

³ Deaths within 24 hours after birth per 1,000 live births.

As shown by the data in table 4, the fetal death rate increased steadily with advancing age of the mother, with a sharp increase after age 35 years. The early neonatal death rate was definitely higher only in the groups aged 35 years and over. Since the number of early neonatal deaths is much smaller than that of fetal deaths, however, the variations in the early neonatal death rates are not as significant.

A crude index of the relationship of socioeconomic status and fetal and early neonatal mortality among Syracuse residents is presented in table 5. The census tracts are grouped by descending status from the highest in group I to the lowest in group VI. It should be emphasized that the considerable degree of variation in socioeconomic status within the census tracts may tend to reduce the sharpness of any differences among the various tracts. No trend in the fetal death rates is discernible with change in socioeconomic status. On the other hand, the early neonatal death rate, even though based on smaller numbers, shows a distinct increase with decline in socioeconomic status.

Table 6 shows the extent of agreement, within 2 weeks, of the length of gestation as calculated from 382 hospital records with that stated on

² Within 24 hours after birth.

stillbirth and live birth certificates. (Only fetal deaths after 20 or more weeks of gestation are reportable in New York State outside New York City.) Among both the fetal deaths and the early neonatal deaths there is about two-thirds agreement. There appears to be greater agreement at and around term than at other periods of gestation.

An analysis of the extent and kind of vital registration according to the World Health Organization classification of deaths is presented in table 7. The greatest degree of under-registration among the deaths for which reporting is mandated was found among the intermediate fetal deaths. In this group, stillbirth certificates were filed for only 52 out of 123, or 42 percent of the deaths. Among the 216 late fetal deaths, 94 percent were registered as stillbirths. Of the 194 early neonatal deaths, 97 percent were registered as births and deaths, 1 percent were registered as stillbirths, and 2 percent were not registered.

Comparison of evidence of life found in hospital records with the kind of vital record filed revealed a close correspondence between the two (table 8). Of the deaths with evidence of life indicated in the hospital record, all but six had birth and death certificates filed. Among

these six, there were two registered as stillbirths. One of these, at 22 weeks' gestation, was stated to have had a detectable heartbeat for several minutes. The other, surprisingly, had a calculated length of gestation of 40 weeks and was stated to have lived for 7 hours.

There were four deaths with recorded evidence of life which were not registered. Every one of these had periods of gestation of less than 20 weeks, and in each instance the evidence of life after delivery was fleeting. The large number of instances in which there was no specific reference on the hospital record to presence or absence of life is rather striking.

The relationship between the physician's statement of the outcome of pregnancy in clinical terms to the outcome according to the World Health Organization classification was the final point investigated. Roughly, the term "abortus" or "abortion" corresponds to early fetal death, "miscarriage" to intermediate fetal death, and "stillbirth" to late fetal death. Comparison revealed the greatest degree of agreement, 92 percent, between the physician's statement of abortion and early fetal deaths among those classifiable by the World Health Organization's definitions (table 9). Agreement between the use of the term "stillbirth" and the classification as late fetal death, 82 percent, was less, but only in the use of the term "miscarriage" was there a gross discrepancy. Only 5 out of 23 deaths called miscarriages with calculable periods of gestation, or 22 percent, fell within the limits for intermediate fetal deaths. Fourteen, or 61 percent, corresponded to early fetal deaths, and 4, or 17 percent, to late

Table 8. Relation between evidence of life and extent and kind of vital registration, Onondaga County, N.Y., 1951-52

¹ Within 24 hours after birth.

fetal deaths. A larger proportion of deaths termed miscarriages were not classifiable by World Health Organization definition than either abortions or stillbirths.

Summary

A study was made of 1951 and 1952 hospital records in Onondaga County, N.Y., to determine the incidence of fetal and early neonatal losses.

Of the total of 1,456 fetal deaths, 67.7 percent occurred before 20 weeks of gestation, 8.4 percent between 20 weeks and 28 weeks, and 14.8 percent after 28 weeks; 9.1 percent could not be readily classified. The proportions of classifiable fetal deaths in the early, intermediate, and late groups were very similar to those found in New York City studies based on reports to the city health department.

The fetal death rates and, to a lesser extent, the early neonatal death rates increased with advancing age of the mother. No trend was discernible in the fetal deaths with change in socioeconomic status of the census tract of family residence, but the early neonatal death rate was inversely related to socioeconomic status.

Agreement between the length of gestation calculated from the hospital records and that stated on the registration forms was about two-thirds for both fetal and early neonatal deaths. Under-registration was greatest for the intermediate fetal deaths, with only 42 percent of such deaths registered. Only 6 out of 182 deaths with evidence of life indicated in the hospital records, however, did not have live birth and death certificates filed. In comparing the physician's statement of the outcome of pregnancy with the classification of the deaths according to the World Health Organization definitions, agreement was lowest between the term "miscarriage" and the corresponding classification of intermediate fetal death.

Sampling Microbiological Aerosols

ANALYSIS of biological forms in the atmosphere has not, until recently, enjoyed the attention given to the study of chemical, inert, and radioactive pollutants. However, the emergence of antibiotic resistant staphylococcal strains in hospitals, the high prevalence of minor respiratory illness revealed by the U.S. National Health Survey, and the potentialities of biological warfare have stimulated attention to the processes of airborne infection and the use of instruments to detect, identify, and assess biological contamination of the air. In particular, instrument methods are sought to sample the flora of the atmosphere.

This monograph acquaints personnel in hospitals and government and private research laboratories and other interested persons with the principles and problems of sampling airborne micro-organisms and with the numerous devices that can be used for a variety of air-sampling conditions. It serves as an aid to those establishing and conducting a biological air-sampling program by supplying information concerning bacterial air-sampling methods, particle sizing, selection of samplers, operational methods, and descriptions and characteristics of many different biological air samplers.

The basic methods of aerosol sampling are: impingement in liquids, impaction on solid surfaces, filtration, sedimentation, centrifugation, electrostatic precipitation, and thermal precipitation. Samplers based on all of these methods have been developed and are described in the monograph.

When selecting a sampler for a specific sampling program one must first have a clear understanding of the type of information that is desired and the particular determinations that must be made. For example, in the studies of airborne micro-organisms and their relation to respiratory infections, information is required concerning the size of the sampled particles. This can be obtained by use of impac-

tion-type samplers, which contain a series of stages through which air passes at different velocities.

For other studies it may be desirable to determine how the airborne microbiological content varies with time. This also can be accomplished with impaction-type samplers if the impacting surface is moved in such a way that the location of the aerosol particles on the collecting surfaces indicates the time that the particles were collected.

No one type of sampler can provide the answers required for all sampling problems. It is because of this consideration that so many different types of aerosol samplers have been de-

Public Health Monograph No. 60

Sampling Microbiological Aerosols. By Harold W. Wolf, Peter Skaliy, Lawrence B. Hall, Marvin M. Harris, Herbert M. Decker, Lee M. Buchanan, and Charles M. Dahlgren. Public Health Monograph No. 60 (PHS Pub. No. 686), 53 pages, illustrated. U.S. Government Printing Office, Washington, D.C., 1959, 45 cents.

The accompanying summary covers the principal contents of Public Health Monograph No. 60, published concurrently with this issue of *Public Health Reports*. This monograph is the joint work of members of the Technical Development Laboratories, Communicable Disease Center, Public Health Service, and the U.S. Army Chemical Corps, Fort Detrick, Md.

For readers wishing the data in full, copies are on sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. Official agencies and others directly concerned may obtain single sample copies without charge from the Public Inquiries Branch, Office of Information, Public Health Service. Copies will be found also in the libraries of professional schools and the major universities and in selected public libraries.

veloped. To help the investigator select the type most adaptable to his particular problem, a table lists the samplers according to the basic methods of aerosol sampling and gives operating characteristics and limitations of each type.

A section devoted to operational methods discusses the control and measurement of air-sampling rates, sterilization of samplers, formulations of bacteriological media and collecting fluids, and processing of samples. It contains formulas for computation of sampling data.

Another section contains suggestions for consideration when planning a sampling program. Since selection of a proper sampler is also de-

pendent upon the expected concentration that must be sampled, information is provided on the normal bacterial levels found in an industrialized urban area and in a rural area. Bacterial levels created by various activities inside several buildings are also presented.

The final chapter illustrates 37 different biological samplers. Accompanying each illustration is a detailed description of the sampler, including operating information. References relating to the use of the sampler and the commercial source are listed. If the sampler is not commercially available, a source is given where engineering drawings can be obtained.

International Conference on Mental Retardation

A pioneer worldwide medical conference for the purpose of bringing into sharper focus and evaluating causes of mental retardation was held in Portland, Maine, July 27-31, 1959. More than 600 conferees representing 40 States in this country and 33 foreign lands attended the sessions.

Underscoring the need for continuing research in mental deficiency, the First International Medical Conference on Mental Retardation set up a permanent organization for concerted work. A permanent committee was organized of physicians from Wales, Germany, Austria, Sweden, Denmark, Italy, Poland, France, Argentina, and the United States. Dr. K. Kundratitz of Vienna, Austria, was named chairman. That city was selected for the 1961 conference.

Featuring 35 speakers, the program included reports on pathological findings in the brain of mentally retarded patients; malformations produced in animals by abnormal food, poisons, or other types of damage; inborn metabolic errors explained by abnormalities in the enzyme function; experiments

in autonomic regulation in the brain; pathological findings in birth trauma and asphyxia; differences of metabolism and oxygen utilization in animals before and after birth; sequels of infectious diseases of the central nervous system in respect to mental development; metabolism of the amino acids and the diseases now considered related to abnormalities in amino acid metabolism; the metabolism of copper, iron, and lead and related diseases with mental deterioration; and recent findings of chromosomal abnormalities in mentally retarded persons.

Conference exhibits included aspects of phenylketonuria; a simple method for the detection of amino-aciduria; rare types of mental deficiency; toxoplasmosis; and ataractics in the treatment of mentally retarded children.

The conference recommended that all governments of the world set aside sufficient funds for furthering knowledge of mental retardation, as well as its medical treatment and social and educational needs.

Proceedings of the conference will be available in published form in the spring of 1960.

Federal Publications

Proceedings of the 1959 Annual Conference of the Surgeon General, Public Health Service, With State and Territorial Mental Health Authorities. *PHS Publication No. 705; 1959; 36 pages.*

Addresses and actions of the annual conference of the Surgeon General with mental health authorities are reported. This is his first conference with this group at a time different from the meeting with State and Territorial health officers.

Recommendations pertain to the use of Hill-Burton funds for joint interstate facilities, an ad hoc committee to work with the Service in formulating treatment and administrative guidelines for statewide plans for mental health facilities, study of patient-care costs, training and research programs, matching requirements for community mental health grants, additional grant aid where needed, amendment of social security laws relating to mental health patients, projects in research applications, aftercare programs and services, and vocational rehabilitation.

Health Statistics From the U.S. National Health Survey. Limitation of activity and mobility due to chronic conditions, United States, July 1957-June 1958. *PHS Publication No. 584-B11; 1959; 40 pages; 30 cents.*

Activity limitation data in this report refer to persons reported in household interviews as being unable to carry on their major activities of working, keeping house, or going to school; limited in amount or kind of major activity; or not curtailed in major activity but otherwise restricted. Mobility limitation data describe persons having difficulty getting around alone, unable to get around alone, or confined to the house. Twenty tables show numbers and percentage distributions by major activity, family income, sex and age, sex and urban-rural resi-

dence, and age and urban-rural residence.

The appendixes carry technical notes on methods, definitions of terms, and a reproduction of the questionnaire on which the information was elicited.

Sanitary Engineering Manpower. *PHS Publication No. 703; 1959; by Frank A. Butrico and Israel Light; 32 pages; 25 cents.*

An attempt to assess the strength of the sanitary engineering specialty, this booklet presents a composite picture of almost two-thirds of the total estimated sanitary engineers in the country. It gives the age, education, professional experience, years of service, kind of work and type of employer, income, and related characteristics of approximately 4,000 such engineers.

The original data were gathered in cooperation with the National Science Foundation's Scientific and Engineering Manpower Unit.

Bibliography on Cancer for Nurses. *PHS Publication No. 687 (Public Health Bibliography Series No. 26); 1959; by Patricia B. Geiser; 38 pages; 20 cents.*

Four hundred and fifty-one selected references and thirty-seven films are listed to help nurses and nursing students locate source material from nursing and other related fields. References from professional journals and the films are annotated.

A list of companies that manufacture prosthetic devices and equipment used in the care of patients with cancer is also provided.

Methods of Making Sanitation Ratings of Milk Sheds. *PHS Publication No. 678; 1959; 19 pages; 15 cents.*

Procedures for evaluating community milk supplies are presented to help State milk control authorities measure objectively the extent to which communities adopting the

Milk Ordinance and Code recommended by the Public Health Service are enforcing its provisions. Figures are included to show how data collected are tabulated and the numerical rating calculated.

This booklet can also be used as a guide for rating interstate milk supplies under the cooperative State-PIIS voluntary program.

Examinations for Cervical Cancer. *PHS Publication No. 707; 1959; leaflet.* Intended for private practitioners and physicians attending beneficiaries of governmental medical care. Briefly describes digital and visual examinations, Papanicolaou smear, and Schiller test and biopsy. Outlines steps in prevention and control of cervical cancer. Depicts advantages of early diagnosis.

Facts on Blindness in the United States. *PHS Publication No. 706; 1959; 6 pages; single copies 5 cents, \$2.50 per 100.*

Written for the general public, this leaflet is intended for use by health departments and community groups in promoting information programs and glaucoma casefinding activities.

It identifies the 10 leading causes of blindness and emphasizes the importance of periodic physical examinations in preventing unnecessary loss of sight. Text and tables present basic information on incidence and prevalence of blindness and the cost of financial aid to the blind.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D.C.

The Public Health Service does not supply publications other than its own.

EXPERIMENTAL STUDIES OF NATURAL PURIFICATION IN POLLUTED WATERS

IV. THE INFLUENCE OF THE PLANKTON ON THE BIOCHEMICAL OXIDATION OF ORGANIC MATTER

By C. T. BUTTERFIELD, *Bacteriologist*, W. C. PURDY, *Plankton Expert*, and E. J. THERIAULT, *Chemist*, *United States Public Health Service*

The abstraction of dissolved oxygen from polluted water during the natural purification process is a well-known phenomenon. It is also well known that the amount of dissolved oxygen used up is definitely related to the amount of pollution present. While these facts in regard to the natural purification of polluted water are well established, the mechanism by which the oxidation is accomplished can only be surmised. For instance, if a portion of polluted water is examined, many bacteria and plankton are found. If all of these organisms are killed or removed from the water, oxidation ceases. The interrelations of these biological factors and the part that each plays in the process of natural purification constitute the subject of this study.

Extensive studies are described in the literature on the rate and extent of biochemical oxidation of polluted water. In general, these studies have been confined to a determination of the amounts of dissolved oxygen absorbed after various periods of incubation at different temperatures without reference to the biological factors con-

FEBRUARY 20, 1931, pp. 393-426

C. T. Butterfield, W. C. Purdy, and E. J. Theriault advanced the theory that the chief function of certain plankton in the biochemical oxidation process was to reduce bacteria below the saturation point, thus providing conditions suitable for bacterial multiplication, which resulted in more complete oxidation. In a series of seven articles they reported experimental studies of the interaction of biological factors in the natural purification of polluted waters.

1959 INDEX

Public Health Reports

Volume 74, January–December

and

Public Health Monographs

Numbers 56–60

THIS INDEX to *Public Health Reports* and Public Health Monographs is divided into a subject index and an author index.

The subject index carries one or more entries for each item published. In addition to the subject headings, categorical headings include ANNOUNCEMENTS (EXAMINATIONS, ORGANIZATIONS, PERSONNEL), CONFERENCE REPORTS, DEATHS, LEGAL NOTES, and MONOGRAPHS.

Public Health Monographs published concurrently with *Public Health Reports* in 1959 are listed in numerical order under the category heading MONOGRAPHS. The monograph summaries appearing in the journal are indexed under appropriate subject headings.

One asterisk before the page number indicates an original, signed article. The sign of two asterisks, used only in the author index, indicates a monograph. Entries without any symbol may refer to summaries or briefs of papers presented at conferences, narrative conference reports, statements or reports of committees, short reports without authors, or similar items.

Illustrative material on the inside of the front cover of each issue is indexed by month under the heading FRONTISPIECES. It is recommended that the covers be included in a bound volume.

An annual list of Public Health Service publications may be obtained from the Public Inquiries Branch, Office of Information.

Division of Public Health Nursing, PHN, established.....	83

THIS INDEX to *Public Health Reports* and Public Health Monographs is divided into a subject index and an author index.

The subject index carries one or more entries for each item published. In addition to the subject headings, categorical headings include ANNOUNCEMENTS (EXAMINATIONS, ORGANIZATIONS, PERSONNEL), CONFERENCE REPORTS, DEATHS, LEGAL NOTES, and MONOGRAPHS.

Public Health Monographs published concurrently with *Public Health Reports* in 1959 are listed in numerical order under the category heading MONOGRAPHS. The monograph summaries appearing in the journal are indexed under appropriate subject headings.

One asterisk before the page number indicates an original, signed article. The sign of two asterisks, used only in the author index, indicates a monograph. Entries without any symbol may refer to summaries or briefs of papers presented at conferences, narrative conference reports, statements or reports of committees, short reports without authors, or similar items.

Illustrative material on the inside of the front cover of each issue is indexed by month under the heading FRONTISPICES. It is recommended that the covers be included in a bound volume.

An annual list of Public Health Service publications may be obtained from the Public Inquiries Branch, Office of Information.

CHILD HEALTH AND WELFARE--Continued

EDITOR'S CORRECTION

In the article entitled "Inapparent Infection: Relation of Latent and Dormant Infections to Aerobial Persistence," by Walsh McDermott, M.D., *Public Health Reports*, June 1959, the seven paragraphs beginning with "It might well be questioned . . ." on page 493, middle of the first column, and ending with ". . . with dysentery bacilli" on page 494, bottom of first column, should be inserted on page 489, second column, preceding the subhead "The Antimicrobial Drug."
